In America the blue crab ranges from Nova Scotia to Uruguay, but is common only along the American coast from Cape Cod to Louisiana. Especially the young prefer sheltered bays or estuaries, and are occasionally found in fresh water. Correspondingly, all the five European records are from fresh water or more or less brackish water.

(2) *Rhithropanopeus harrisi* (Gould). In November 1953 Mr. Erik Rasmussen found plenty of crabs of this species on piles in the South Harbour of Copenhagen. They were all quite small (6–7 mm.). In the middle of t ice winter another visit to the known localit in the harbour only gave four specimens in a ranging in width from 6·8 to 10·5 mm. This pa of the harbour was the only area free of ice, becau waste water from a nearby factory raised t temperature to 6° C.

In eastern America this species occurs locally estuaries from Nova Scotia to Mexico. Previo records outside this area are: (1) San Francis Bay[3]; (2) Coos Bay, Oregon[4]; (3) Holland, whe until 1949 the crab was regarded as endemic (it w known as the Zuiderzee crab, *Heteropanope tridenta* Maitland, but is now considered a subspecies, *R. tridentata* Maitland)[5]; (4) Flemhuder Lake near t Kiel Canal in North Germany[6]; (5) estuaries of t Rivers Dnieper and Bug in the Black Sea[7].

Transportation of *Callinectes sapidus* to Europ and of *Rhithropanopeus harrisi* to Holland (befo 1874, when the Zuiderzee crab was described) and the Black Sea may have taken place in various wa Many examples are known of crabs clinging to shi sides or living in growths of algae, etc., on ships' hu (*Pachygrapsus transversus*, *Plagusia chabrus*, *depressa* and *P. tuberculata*, *Planes minutus*, *Ca cinides maenas*, *Menippe convexa*, etc.). In m opinion, this mode of transportation does n however, apply either to *C. sapidus* or to *R. harri* The former never occurs on piles, etc., or see shelter in crevices (as do the species mentioned abov and the latter is a brackish-water crab which cou scarcely withstand transportation for several wee through sea water of high salinity. It is more like that the two species have crossed the Atlantic in t ballast tanks of ships. This was probably the w in which the mitten crab (*Eriocheir sinensis*) w brought to Europe, as shown very convincingly Peters and Panning[8]. Another possibility in the ca of the blue crab may be active swimming, presumab in the shadow of floating sea weeds or wood, tr trunks, etc., carried by the Gulf Stream. During t

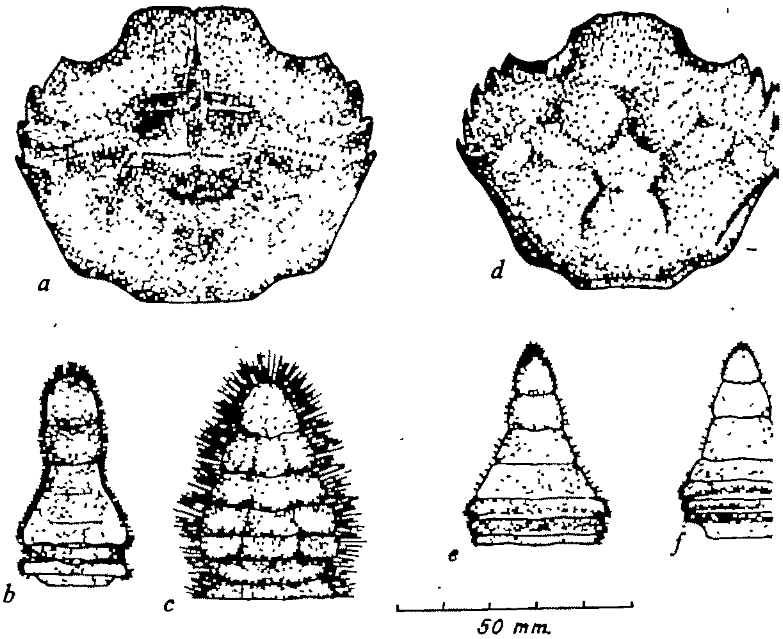

Fig. 1. (*a–c*) *Rhithropanopeus harrisi*; (*d–f*) *Carcinides maenas*; (*a, d*) carapace; (*b, e*) male abdomen; (*c, f*) female abdomen

alathea Deep Sea Expedition, I several times saw astal swimming crabs together with numerous astal fish, other Crustacea, etc., seeking shelter nd shadow under such floating objects, far from nd.

It is reasonable to suppose that finds of *Callinectes pidus* are normally recorded, since this crab is so g and conspicuous. But *Rhithropanopeus harrisi* ever exceeds some 25 mm. and can easily be istaken for a juvenile shore crab, *Carcinides maenas*. can be distinguished by the presence of only three ntero-lateral teeth and the conspicuous lines of ranules on the carapace (Fig. 1*a* and *d*).

In Holland the two species are known to occur gether[6]; but at Copenhagen *Rhithropanopeus* seems fill an ecological niche, occurring in the South arbour where the salinity (normally $9-12^{\circ}/_{00}$) is o low for *Carcinides*, which only penetrates into e Middle Harbour.

Modified Horizontal Migration Method in Paper Chromatography

Very recently, Matthias[1] has described a modified echnique which may be looked upon as a combination f uni-dimensional and circular paper chromatoraphy. In this case, substances to be chromatoraphed are applied near the edge of a strip of aper, the end of which is made in the form of cone; thus the substances are at first radially istributed, which results in better separation.

We have developed a further odification. Whatman No. 1 lter paper sheet (18·5 cm. × 18·5 m.) or circular paper (18·5 cm. iameter) is cut as shown in Fig. 1. he black rectangles indicate openngs of equal size on paper at equal ntervals; thus, *A*, *B*, etc., may be oked upon as a number of strips ined together. The samples are pplied at *X* and, as in circular aper chromatography, paper wicks f equal size (2·0 cm. × 1·5 cm.) re inserted at *W*, so that one ick develops two samples at a ime. The piece of paper (sheet or ircular) is then placed between wo Petri dishes of the same diaeter (16·0 cm.), inverted one over e other, in which there is another maller Petri dish (10·5 cm. diaeter) containing the developing lvent. Development starts simultaneously through all the wicks and is complete within 30 min. Detection and identification of the samples are as usual. Fig. 2*a* shows the resolution achieved by the modified technique; twenty-two samples of varying concentrations were chromatographed on a sheet of paper 11 cm. × 18·5 cm. The solvent was allowed to travel a distance of 7 cm. The effective travel can be doubled if the wicks are transferred from the centre to the periphery of the paper, as shown earlier[2] for circular paper chromatography; but in this case only half the number of samples can be analysed. The 'cuts' in the paper can be of various shapes and sizes, provided that the solvent front moves radially at first. The poor resolution of the same sample on ordinary strip without 'cuts' is shown in Fig. 2*b* for comparison. Since there is clear separation of the constituents by the modified technique, quantitative analysis by elution can be done very easily in this case.

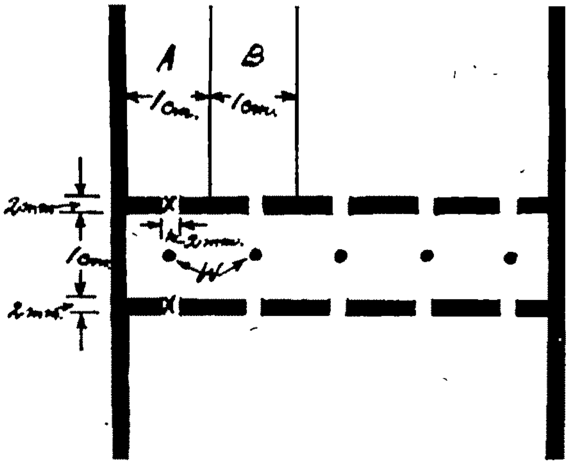

Fig. 1

As was pointed out earlier, all these improved methods depend upon the radial distribution of the chromatographed substances, at least in the beginning of development. In the case of strip chromatography, spots are formed which are generally elongated in the direction of the flow of solvent. This results in the merging of spots of close R_F values. In circular paper

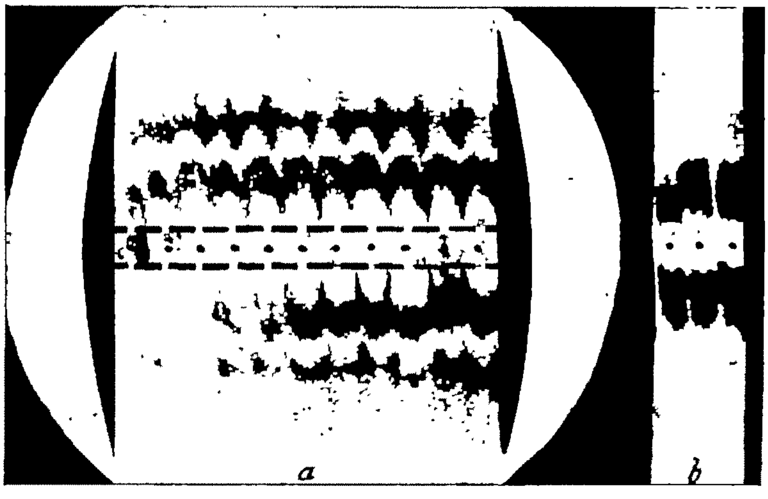

Fig. 2. Samples of amino-acid mixture of varying concentration which have been chromatographed with butanol : acetic acid : water (40 : 10 : 50)

chromatography or in these improved techniques, the substances form either rings or arcs; that is, elongation takes place at right angles to the direction of flow of solvent. This helps to increase the distance of separation between substances of close R_F values and therefore results in improved separations.

I wish to thank Dr. S. C. Roy, of this College, for his interest, and Dr. D. P. Burma, Bose Research Institute, Calcutta, for helpful criticism.

Staining of Bound Lipids

METHODS at present used for staining bound lipids either give an inadequate result histologically or depend on chemical reactions not characteristic of lipids as a class.

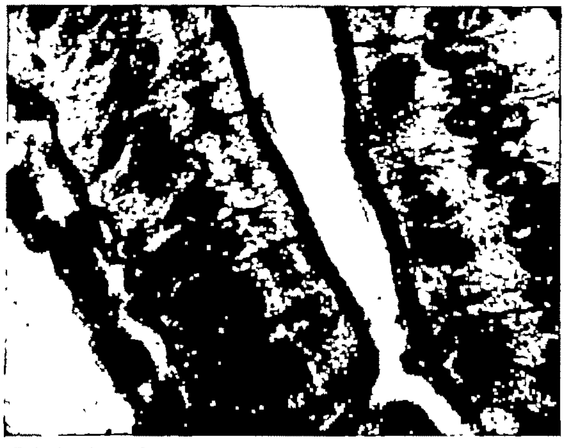
It has been found that if paraffin sections of variously fixed tissues are washed in water for several hours, and then rinsed in alcohol, they are well stained by 2 per cent sudan black *B* in acetone at 37° C. Staining is carried out in an airtight container, is progressive, taking one to twelve hours, and is followed by rinsing in xylol and mounting.

Structures stained include those containing nucleic acids, various cytoplasmic particles, nerve cells and processes, corpora amylacea, lipofuscin, basement membranes, reticulin, collagen, cartilage matrix, mucin, fibrin, amyloid, muscle striations, pituitary and thyroid colloid, bacteria and epithelial brush borders.

Alternatively the sections, washed as above, or exposed to dry heat at 60–65° C. for some hours, may be stained by burning saturated sudan black *B* in 70 per cent alcohol over them[1] six to ten times, washing in alcohol, clearing and mounting.

Here stained structures are those containing nucleic acids, red cells, erythroblast cytoplasm, eosinophil granules, muscle striations, cartilage matrix, mucin, lipofuscin, bacteria and thyroid colloid.

Continuous refluxing of tissues with ethanol–ether, methanol–chloroform and *n*-butanol–petroleum–ether mixtures progressively reduces stainability, litt being left after extraction for two weeks. The difficulty of disrupting some lipoprotein bonds by solven alone is well known[2].



Intestinal epithelium of guinea pig; alcohol-fixed; washed 24 hr.; acetone – sudan black 6 hr. Showing staining of brush border, cytoplasmic granules, nuclei and basement membrane

It is postulated that washing dissociates protei from laminated lipoproteins, allowing access to th stain[3].

This hypothesis is supported by the effect of mil peptic digestion (0·2 per cent pepsin in 0·05 hydrochloric acid for 30 min. at 37° C.) and of soap (1 per cent sodium ricinoleate at *p*H 7 for 1 hr. 37° C.), after either of which procedures sectio stain intensely without further washing.

This evidence suggests that these methods sta lipids bound to protein, and possibly to carbohydra and nucleic acids.

It is hoped to publish a full account of this an related work in due course.

Extension of Range of the Angwantibo

I WISH to correct a pardonable error in the revie of "The Overloaded Ark" published in *Nature* May 15, one in fact which I myself held until ver recently. *Arctocebus calabarensis* is not found onl in the forests of the British and French Cameroon Two specimens of it have, a short time since, bee taken in the Mamu River Forest Reserve, a patch isolated remnant high forest situated some thirt miles east of Onitsha on the left bank of the Nige

This is an interesting if not important discover since it extends the known range of this animal we beyond what is with some justification regarded as faunal frontier precluding several animals of the mai central African forest block from the West Africa block—the Cross River basin. The Angwantib which in its main habitat cannot truly be describe as a "very rare" lemuroid, was certainly regarded one of the chief of these; so, too, was *Hylarnu batesi*, which has likewise been captured well to th west of the Cameroons.

The high forests lying between the Cross Rive and the Niger, that is, in the densely populou Eastern Region of Nigeria, have been very largel destroyed, and it is thus difficult to determin precisely the limits of the central African block. I our present state of knowledge there appear, however, to be indications from plants as well as anima that it is the somewhat insignificant Cross Rive rather than the Niger which forms the dividing lin To a scientific worker interested in animal di tribution, investigation of the few remaining an little-known forest remnants of the Eastern Regio of Nigeria, rather than the over-done Cameroon would be well rewarding.

D. R. ROSEVEAR
(Inspector-General of Forests)

Lagos,
Nigeria.

APPOINTMENTS VACANT

pplications are invited for the following appointments on or ore the dates mentioned:

urator (with a degree in geology) in the Geology Department Head of the Geology Department, Imperial College, South Kensing-, London, S.W.7 (July 28).

ecturer (with special interests in animal husbandry) in Agri-ture—The Registrar, The University, Nottingham (July 28).

emonstrators (with an honours degree in chemistry) in Chem-ry—The Registrar, College of Technology, Manchester (July 29).

cientific Officer or Senior Scientific Officer (with a first-second-class honours degree in physics or chemistry, and with eral years experience in the study of surface chemistry), to work problems associated with the surface chemistry of materials of erest in the nuclear energy field—The Establishment Officer, omic Energy Research Establishment, Harwell, Berks (July 29).

ecturers (with a good honours degree in electrical engineering) Electrical Engineering—Head of the Electrical Engineering partment, City and Guilds College, London, S.W.7 (July 30).

esearch Assistant (with a good degree in botany and high ualifications in chemistry and with physics to at least introductory al) to the Professor of Plant Biophysics in the Department Botany, to study problems in growth and senescence of apple cell lls using electron microscopy and other physical methods—The gistrar, The University, Leeds 2 (July 30).

enior Lecturer (with high academic and research qualifications) Organic Chemistry—The Clerk to the Governors, Woolwich lytechnic, London, S.E.18 (July 30).

ssistant in Mathematics, and an Assistant in Statistics—e Secretary, The University, Aberdeen (July 31).

hair of Chemistry—The Secretary, The University, Aberdeen ly 31).

Lecturer (preferably with an interest in low-temperature physics in the theory of the solid state) in Physics, at St. Salvator's College The Secretary, University of St. Andrews, College Gate, St. Andrews ly 31).

emonstrator (with a good honours degree in chemistry or bio-mistry, and prepared to engage in research in biochemistry with a w to obtaining a higher degree in this subject) in the Department Chemistry and Biochemistry—The Dean, St. Thomas's Hospital dical School, London, S.E.1 (August 3).

cientific Assistant (with a knowledge of systematic zoology l/or foreign languages), for duties which will include abstracting, lexing and proof reading—Commonwealth Bureau of Agricultural rasitology (Helminthology), Winches Farm Drive, Hatfield Road, Albans, Herts (August 4).

Principal Scientific Officer (with an honours degree in civil gineering or Corporate Membership of the Institute of Civil gineers) at the Road Research Laboratory, Harmondsworth, iddlesex, to take charge of full-scale experiments in bituminous road struction and occupy a senior position in the section dealing with earch on bituminous materials—The Civil Service Commission, entific Branch, 30 Old Burlington Street, London, W.1, quoting 356/54 (August 12).

ssistant in Research in Animal Physiology; an Assistant Research in Soil Chemistry, and an Assistant in Research Agricultural Engineering—The Secretary, School of Agri-ture, Downing Street, Cambridge (August 13).

Lecturer or Assistant Lecturer (preferably with experience of iversity teaching and with special qualifications in petrology or physics) in the Department of Geology—The Secretary and gistrar, The University, Southampton (August 13).

enior Lecturer in Education at the University of Sydney, stralia—The Secretary, Association of Universities of the British mmonwealth, 5 Gordon Square, London, W.C.1 (Australia, August

ollege Lecturer in Electrical Engineering, and a College cturer in Mechanical Engineering—The Secretary, University lege, Cork, Ireland (August 16).

ecturer (with a good honours degree in mechanical engineering l practical experience in industry and teaching) in Mechanical gineering—The Principal, Wigan and District Mining and Tech-al College, Wigan (August 16).

ssistant Lecturer or Demonstrator (with a good honours gree in chemistry or biochemistry) in Chemical Pathology—e Registrar, The University, Manchester 13 (August 25).

ecturer (preferably with qualifications in the fields of human l regional geography, and a special knowledge of the regional graphy of Monsoon Asia and/or the South-West Pacific) in Geo-aphy, at Victoria University College, Wellington, New Zealand—e Secretary, Association of Universities of the British Common-alth, 5 Gordon Square, London, W.C.1 (New Zealand, August 31).

ecturers (2) (with a special interest in one or more of the following ds: clinical psychology (with therapeutic experience), experimental l statistical, physiological, social, industrial) in Psychology, at University of Natal—The Secretary, Association of Universities the British Commonwealth, 5 Gordon Square, London, W.C.1 uth Africa, August 31).

rofessor of Philosophy at the University of Otago, Dunedin, w Zealand—The Secretary, Association of Universities of the tish Commonwealth, 5 Gordon Square, London, W.C.1 (New land, August 31).

enior Lecturer in Pure Mathematics at the University of Witwatersrand, Johannesburg, South Africa—The Secretary sociation of Universities of the British Commonwealth, 5 Gordon uare, London, W.C.1 (Johannesburg, August 31).

lant Pathologist (with a good degree in botany, including cology, and preferably with postgraduate research experience or ivalent training in plant pathology or mycology) for research on fungal diseases of hops and fruit—The Secretary, East Malling Research Station, near Maidstone, Kent (September 1).

Lecturer in Applied Pharmacology and Therapeutics—The Dean, St. Thomas's Hospital Medical School, London, S.E.1 (September 6).

Lecturer (well qualified in organic chemistry, and preferably with experience of the chemistry of vegetable tannins or synthetic dyestuffs) in the Department of Leather Industries—The Registrar, The University, Leeds 2 (September 13).

W. J. Rees Research Fellowship, tenable in the Department of Refractory Metals in the Faculty of Metallurgy—The Registrar, The University, Sheffield (September 15).

Senior Technician (with some training in zoology and experience in laboratory work, and preferably with a practical knowledge of taxidermy and modelling) in Zoology, at Auckland University College, Auckland, New Zealand—The Secretary, Association of Universities of the British Commonwealth, 5 Gordon Square, London, W.C.1 (New Zealand, September 30).

Agronomist/Plant Breeder (with a degree in agriculture or botany, and preferably with some postgraduate experience) on the Research Staff of the Empire Cotton Growing Corporation, Aden, to work on general problems of agronomy and plant breeding, and selection work on the irrigated cotton crop, and to some extent on food crops; and a Soil Chemist or Physicist, to study the soils in Aden Protectorate and possibly Somaliland—The Secretary, Empire Cotton Growing Corporation, 12 Chantrey House, Eccleston Street, London, S.W.1.

Assistant Experimental Officer (with at least H.S.C. in science or mathematics) in the Department of Atomic Energy, Risley, for technical information duties, which include preparation of bibliographies, bulletin of journal references, and maintenance of indexes—The Department of Atomic Energy, Industrial Group Headquarters, Risley, Warrington, quoting 638.

Assistant Experimental Officers (with at least H.S.C. in mathematics or science subjects, or equivalent) in the Department of Atomic Energy, Capenhurst, near Chester, for (*a*) work in a small computing section (after a period of training); (*b*) theoretical investigations, under supervision, of problems arising in the development of power producing reactors and diffusion plant; (*c*) assisting in research concerned with development in fields such as fluid dynamics, mass spectrometry, heat transfer and general physics—The Department of Atomic Energy, Industrial Group Headquarters, Risley, Warrington, quoting 637.

Assistant Lecturer in the Department of Pure Mathematics—The Registrar, University College of Wales, Aberystwyth.

Chemical Engineer (with an honours degree, A.R.I.C., A.M.I.Chem.E., or equivalent qualifications, and at least three years experience in an industrial research organization) in the Department of Atomic Energy, Sellafield, Cumberland, to lead a team working on chemical engineering problems connected with the development of new processes—The Department of Atomic Energy, Industrial Group Headquarters, Risley, Warrington, quoting 632.

Chemist, to work in the United Birmingham Hospitals Department of Clinical Endocrinology, on an investigation of protein hormones—The House Governor, Birmingham and Midland Hospital for Women, Showell Green Lane, Birmingham 11.

Electronics Technician, to work on the 8 MeV. Linear Accelerator—The Director, Radiotherapeutic Research Unit, Hammersmith Hospital, Ducane Road, London, W.12.

Lecturer, Grade IIa (with an honours degree or equivalent qualification, and preferably industrial and/or research experience) in Physics—The Principal, Paisley Technical College, Paisley.

Lecturer in Market Garden and Glasshouse Crops—The Clerk to the Governors, Essex Institute of Agriculture, Writtle, Chelmsford, Essex.

Lecturer (with special qualifications in pure mathematics) in Mathematics—Head of the Mathematics Department, Imperial College, London, S.W.7.

Master to teach Physics to Scholarship level—The Warden, The College, Llandovery, Carmarthenshire.

Physicist (preferably experienced in instrumentation, with particular reference to the inspection and testing of metallic materials)—The British Non-Ferrous Metals Research Association, 81 Euston Street, London, N.W.1.

Physicist, to continue fundamental research on surface electrification of polymers—The Secretary, British Rayon Research Association, Heald Green Laboratories, Wythenshawe, Manchester.

Physicist (with a good honours degree) for technical assessment and development of inventions chiefly in the applied physics and scientific instrument field—The Secretary, National Research Development Corporation, 1 Tilney Street, London, W.1.

Physicist or Electrical Engineer (with an honours degree in physics or electrical engineering), for work with a 1-million-volt cascade generator—Dr. J. F. Loutit, Medical Research Council Radio Biological Research Unit, Atomic Energy Research Establishment, Harwell, Didcot, Berks.

Research Assistants in Chemistry, Physics and Mathematics—The Northern Polytechnic, Holloway, London, N.7.

Research Officer (with a first-class honours degree in a natural science and at least two years postgraduate research experience, preferably of freshwater fish and fisheries) with the East African Fisheries Research Organization, to carry out research into the ecology and/or physiology of fish—The Director of Recruitment, Colonial Office, Great Smith Street, London, S.W.1, quoting BCD.195/194/02.

Scientific Assistant (with a degree in agriculture or natural science, and a knowledge of French and German and ability to write clear concise abstracts in English), for duties which will include examining and abstracting world scientific literature on grassland and field-crop research—The Director, Commonwealth Bureau of Pastures and Field Crops, Hurley, near Maidenhead, Berks.

Technician or Senior Technician (with some experience of electronic equipment) in the Londonderry Laboratory for Radiochemistry—The Secretary, Science Laboratories, University of Durham, South Road, Durham.

COASTAL FLOODING IN BRITAIN

THE recently published report* of the Departmental Committee on Coastal Flooding is of considerable interest to a wide variety of authorities and individuals. The Committee was appointed in April of 1953 and was charged with the task of examining the causes of the floods on the east coast of Britain which had occurred in the previous January, and with estimating the possibilities of their recurrence. The Committee was also asked to consider what margin of safety for sea defences would be reasonable having regard to the estimated risks and the cost of protective measures, and whether any system of warning was desirable to lessen the risk of loss of life and damage to property. Finally, the existing administrative and financial structure for the maintenance and replacement of sea defences was to be reviewed.

With commendable speed and efficiency the Committee has studied the problem and made its report and recommendations in a little more than twelve months. Indeed, it had already distinguished itself by the early publication of an interim report on a warning system which appeared in July 1953. Priority was given to this aspect of the terms of reference in view of the public anxiety which had been created by the tragic events of January 1953, when more than three hundred people lost their lives, some 24,000 houses and more than 200 large industrial premises were flooded and damaged, and some 160,000 acres of land inundated.

The Committee proposed in this interim report that a winter warning system should operate initially on the east coast of Britain between September 15 and April 30 each year. It was suggested that water-level reports should be sent in to the Central Forecasting Office at Dunstable, where a seconded officer of the Hydrographic Department of the Admiralty would interpret them in the light of predicted tidal levels and the possibility of surges. If dangerous levels were likely to be exceeded, then the river boards and county police were to be informed immediately, and were locally to be charged with the responsibility of giving adequate warning. This system was put into operation and has apparently stood the test of a trial winter season quite satisfactorily.

As is now well known, the severe coastal flooding of January 1953 was caused by the combination of a fairly high tide with a very high surge, and the effect was increased by severe wave action. Tidal oscillations are well-known phenomena and can be predicted with reasonable accuracy, but the surge has only been recognized and studied in the past thirty years. A surge is mainly due to strong winds blowing forward the surface waters of the sea ; this in certain circumstances may lead to an accumulation of water in a particular locality and hence to a rise in sea-level. Smaller differences in level may also be produced by changes in atmospheric pressure from one part of the sea to another. The surge is therefore clearly a meteorological phenomenon, although once the accumulation (or deficit) of water has been formed in any region it will tend to move away from that region according to the laws of mechanics. Forecasting the incidence and periodicity of a surge is difficult, although once established a fairly reasonable estimate of the dispersal behaviour can be made. Here the Committee is strongly in favour of more fundamental research being carried out in order that the warning system can be further improved.

---

* Report of the Departmental Committee on Coastal Flooding. (Cmd. 9165.) Pp. 48. (London : H.M.S.O., 1954.) 2s. 6d. net.

The primary causes of tides and surges are completely unrelated, so that it might seem a maximum in both could coincide. Their combination is not, however, a simple superposition. In steady conditions the slope on the surface produced by a given wind varies inversely with the total depth of water under the wind, so that when the tide is high the slope of the sea surface is somewhat less than when the tide is low. The highest surges have, in fact, reached their greatest heights when the tides have been nearer low water than high water. The flood of January 1953 did not occur at high tide, nor did it occur with the highest spring tides; and the surge, although 9 ft. in height and exceptional, was not the greatest on record. A moderate surge coming near high water on a high spring tide is thus likely to prove even more disastrous. Here again, further information is needed before the precise nature of the interaction between the tide and surge can be understood.

Another somewhat disturbing factor which the investigation has brought to light is the progressive increase over the past hundred years in the highest levels reached in exceptional storms and in the frequencies with which such levels occur on the east coast of Britain. This is largely attributed to the steady rise of mean sea-level relative to the land which appears to be taking place at the rate of one foot per century along the coasts of south-eastern England. Attention is further directed to the effect of large waves upon the coastal defences, since the meteorological conditions favourable to surges will also produce exceptional waves. It also becomes necessary to bear in mind the possibility of upland river flood water adding to tidal and surge waters in constricted estuaries—an important point in the problem of the Thames estuary.

Having established the causes of the severe flooding and shown where additional information is desirable, the report then considers the practical problems of coastal defence which arise on the east coast. Here there are long stretches of natural defences such as dunes and shingle ridges, to which has been added some 1,270 miles of man-made earthen and other types of banks: the whole protecting considerable areas of land now lying well below high-tide level. To reinforce all these defences to meet the maximum water-level that is theoretically possible in the light of present knowledge would of course be financially out of the question. The Committee recommends that the level of January 1953 should be taken as a reasonable working basis for areas of high propert value; elsewhere defences should be at a standar which would have been thought reasonable prior t January 1953. But preparations should be mad where desirable to deal with a limited amount overspill for occasional exceptional water-levels (th statistical chance of the January 1953 level is onc in every two hundred years). Where possible, secon line defences should be strengthened or constructe to create a cell or honeycomb structure which woul contain any overspill flood waters during an eme gency. Where the risk of overtopping is accepte earthen banks should be waterproofed with a carp of material such as asphalt/concrete to preve erosion on the back slopes and the conseque collapses which were so common in 1953. Th sealing of minor tidal creeks is recommended, an the possibility of deliberately spilling water on th seaward side of vulnerable areas is also considered.

The importance of maintaining the natural defenc of dunes and shingle ridges is stressed, together wit the advisability of pressing ahead with research o the behaviour and suitability of binding and stabi izing vegetation for use on such areas. The Committ might also have mentioned the need for a code public behaviour in such localities—few holiday makers and caravan dwellers realize how deleterio their activities can be to the natural coastal defence Further research is also considered advisable int the movements of beach material and offshore san banks, together with the use of groynes as a contr medium for beach retention; conflicting eviden was deposited with the Committee relative to the problems.

Finally, the field of existing responsibilities for th coast protection and defences of eastern England surveyed. As might be expected, there is here complex situation with duties spread over rive boards, county borough councils, county distri councils and government departments, with here an there a part of the coast completely 'unadopted' After careful consideration, however, the Committ does not recommend any change in the distributio of existing responsibilities, but does advise in som instances closer co-operation between certain autho ities. Financial responsibilities are also considered i the report, and an effort is made to lay down som working principles on the problem of who shoul pay for construction and maintenance of th defences.

The special problem of flooding in the Tham receives separate consideration. A surprising amou of the City of London is built on former marsh la and is now below high-tide level; substantial are would be flooded if the embankments were ove topped or gave way. The 1953 flood water general reached the top of the city defences, and low downstream some 30,000 acres were inundated. was fortunate that the down-river inflow was low or much greater damage would have resulted.

Experiments have since been made on the Port London Authority's tidal model of the Thames study the interaction of river flow, tidal changes an surge effects. A complicated picture emerges, as solution in one locality may intensify the problem lsewhere. Thus the raising of the downstream defences in Kent and Essex by 3–4 ft. which followed immediately upon the flood of 1953 will appreciably aise the Thames level in central London should such an incident be repeated; further, any greater surge height at Southend means a progressively greater increase in height upstream towards London Bridge. Relief by means of controlled spill is now almost mpossible, and similarly the raising of the defences of inner London would be extremely difficult and costly because of the associated ancillary work. Two other possibilities were therefore considered: one method would be to erect a barrier across the estuary, leaving gaps through which shipping could pass; but this carries the disadvantage that it would cause deterioration of the estuary. An alternative suggestion which was tried out on the model, and which the Committee recommends for serious consideration, was he construction of a suitable structure across the Long Reach (between Purfleet and Greenhithe) provided with 'gates' which could be closed on occasions of impending high flood.

The report also directs attention to certain unsatisfactory aspects of the present financial and administrative arrangements in the existing Thames flood defence scheme, and to the fact that little positive action followed upon the report of the Hart Departmental Committee of 1931–33, which was set up to consider floods in the tidal portion of the Thames. The present Committee urges that the special problem of the Thames should be resolutely tackled without further loss of time.

This report on coastal flooding is a model of its kind, and one could only wish that the associated, but even more serious and more frequent, problem of river flooding (see *Nature*, 172, 263 and 823; 1953) was also in receipt of equally careful attention and consideration.

ORIGINAL PAPERS OF WILBUR AND ORVILLE WRIGHT

The Papers of Wilbur and Orville Wright

Including the Chanute–Wright Letters and other Papers of Octave Chanute. Edited by Marvin W. McFarland. (Sponsored by Oberlin College on the Wilbur Wright Memorial Fund, and prepared for the Press, with Notes, Appendices, and Bibliography, by the Aeronautics Division of the Library of Congress.) Vol. 1: 1899–1905. Pp. lv+676+141 plates. Vol. 2: 1906–1948. Pp. xxvii+677–1278+plates 142–236. (London: McGraw-Hill Publishing Company, Ltd., 1953.) 2 volumes, £10.

THESE two volumes give for the first time a full account by the Wright brothers of the history of the solution of the problem of human flight. In the ntroduction it is explained that they fully intended to write up the results of their work for publication, but that they became so preoccupied with their experiments and later with the marketing of their machines that they never did so. After Wilbur's death in 1912, Orville had the same good intention, but never carried it out. After his death in 1948, the voluminous correspondence of the brothers and their note-books eventually came into the possession of the United States Library of Congress, and it is from this material that the present volumes have been compiled. The story is told almost entirely by the reproduction of the correspondence in full, so far as it affects the progress of the aeronautical work, with an occasional letter that sheds light on the character and personality of the Wrights. By far the greater part of the letters passed between the Wrights and Octave Chanute, with whom they formed a close friendship in the early days and with whom they discussed, usually by writing, the results of their experiments. It is most fortunate that these letters have been preserved.

The books are by no means easy reading, partly because of the great amount of material in them and partly because the Wrights invented their own terminology, and one must translate it into modern aeronautical nomenclature in order to see precisely what they were thinking. There is, however, a very clear picture of the whole process through which they went, from the first desire to explore the possibility of flight to the successful achievement of powered flight for the first time in history and on again to the development of their machines into forms suitable for practical use in peace and war. The first volume carries the reader from 1899 to 1905 and contains chiefly an account of aerodynamic experiments made to determine the basis on which flight depends. This is unfolded almost entirely by the letters to Chanute and his replies, but in appendixes there is an account of the Wright brothers' nomenclature, of their wind-tunnel experiments and results, and of their study of the problem of the propeller. There are also extracts from Chanute's diary which shed further light on the subject.

The second volume contains later experimental work; but is largely taken up with the efforts made by the brothers, sometimes separately and sometimes together, to obtain some reasonable financial recompense for all their work by selling their invention to governments or private companies, a matter in which they met with no small difficulty. There is also an account, amplified by footnotes, of the various controversies which arose concerning the Wrights' claim to have been the first to fly, and, in particular, of the lengthy battle which raged over the claims of Langley, in which the Smithsonian Institution took, at the time, a rather inglorious part, but later fully recanted.

The broad outline of the Wrights' pioneering work is now fairly well known through details which have been given in Wilbur Wright Lectures and in the publications of the Royal Aeronautical Society and other bodies; but it may be well to direct attention here to salient points. The Wright brothers were no theorists, but practical engineers whose life had started in the cycle trade. They realized, from the start, the extreme importance of obtaining numerical data on the performance of their machines as a basis for future progress. They followed, in fact, the road that has been followed ever since in aeronautical research, combining measurements in flight with experiments on models and endeavouring to correlate the two to form a practical basis for design. In the earliest days they used gliders, which they sometimes flew as kites, and by observations of angles of glide and incidence in the former case, and of tension in the cable in the latter, they were able to get a fairly good quantitative idea of the forces acting on the wings. They soon realized that the existing tables of aerodynamic data, chiefly Lilienthal's, were far from satisfactory, and it was this that led them to devise a wind tunnel in which they could make tests of lift and drag on a whole series of wings of various sections. On these data they based the design of all their subsequent machines, with conspicuous success. They showed the greatest wisdom in their flying, never rising more than a few feet above the ground until they had fully solved the problem of control and had learned how to use that control in all circumstances. They state repeatedly in their letters that the real problem of flight is one of control, rather than the mere provision of wings that can sustain the weight and power to pull them through the air. They did their best to follow the work of others in the field; but it seems fair to say that they owed very little to such work and that from their own resources and tests they evolved the machine, its engine and its propeller, all of which they made with their own hands. This is surely one of the most notable achievements in the history of man. They seem to have been unaware, however, of the writings of Lanchester, and of the theoretical and experimental work of Eiffel and Prandtl; at least, there is no mention of these investigators until almost the last letters of Orville Wright.

It is perhaps surprising that it should be so late before a full account of the Wrights' work has become available. The main reasons are that they themselves did not write out their results, and that they were always careful not to discuss their work, except to close friends, lest they should lose to others some of the credit that they felt was their own. We can now be thankful that the story has at last been told and that the magnificent achievement of the Wright brothers can be appreciated to the full extent it deserves in this air age which they did so much to inaugurate. ERNEST F. RELF

UNIVERSITY OF LEEDS: JUBILEE VOLUME

The University of Leeds

The First Half-Century. By Prof. A. N. Shimmin. Pp. xv+230+8 plates. (Cambridge: At the University Press, 1954. Published for the University of Leeds.) 21s. net.

THIS is a remarkable book about a remarkable institution, and a more fitting foreword than that of its Royal Chancellor can scarcely be imagined. The Princess Royal says: "The making of a University calls for inspiration and enterprise. Although the University of Leeds is still young, the men and women who have created and cherished it have displayed the same devotion to truth in the service of their generation as their forbears in the older Universities. This book is the story of a triumph over many obstacles and over the ill effects of two world wars. So much strength and vigour, gained in so short a time, is good testimony to the loyalty and robust energy of the members of the University themselves. But as the record shows, they have not done what they have done in isolation. Through all the years, while steadily building up its esteem in the world of learning, the University has felt a characteristic impulse from the Yorkshire people whom it serves. In a Jubilee celebration it is most fitting t honour those who have laid the foundations and commend this history to all who care for our University of Leeds. MARY".

In these words Her Royal Highness has mos aptly summarized the intention of the jubilee an the purpose of the commemorative volume which th University authorities so wisely entrusted to the car of Arnold Shimmin, professor of social science.

The volume presents a broad, general, historica sketch of the antecedents of the University and make a most successful effort to indicate the vicissitude and successes from the days of the Medical Schoo (1831); the Yorkshire College of Science (1874) the amalgamation of these two (1884); the federatio of the Yorkshire College in the Victoria Universit (1887); and lastly the granting of a charter t the infant University of Leeds (1904) and so t 1954.

The first pre-natal stirrings are touched on, with reference to an account in the *Leeds Mercury* (1826 of a proposal by the president of the Philosophica and Literary Society of Leeds to establish a universit in Leeds. The scheme was still-born—but was a any rate a stirring of thought. Who knows bu that the processes so started led to the foundatio of a School of Medicine in 1831, for was not the firs president of its Council one Dr. James Williamson who had been the first secretary of the Leed Philosophical and Literary Society?

Prof. Shimmin gives such matters the fulles possible attention in the first of six chapters whic make up Part 1 of the book, entitled "The Makin of the University". In this part, additional to th historical background, are included also such topic as "The Years of Expansion (1925–53)"; "Studen Welfare"; and a revealing section under the title o "Town and Gown".

This Part 1 is the more impersonal of the two mai parts into which the book divides itself. Nevertheless, even the casual reader will realize, as has bee the treasured realization of all members of th University, that distinguished and well-remembere names were foremost among the original teachers i 1874: Arthur Rucker was professor of physics A. H. Green was professor of geology; Edwar Thorpe was professor of chemistry; and these wer soon to be joined by Louis Miall, professor of biology The Yorkshire College of Science had stepped off o the right foot on its path towards university statu and was thus destined, from the start, to be no entirely vocational. Indeed, from one of th appendixes (No. 3) which illumine the historica details, this breadth of vision and balance of stud was (as it still is) well maintained, since, at the tim of the charter in 1904, there were eleven arts departments, six of science, seven of technology and ten o medicine.

During this fifty years, Prof. Shimmin points out many distinguished names have helped in th building up of the external prestige of the Universit and have added to its growing lustre. Such men a George Gordon, Lascelles Abercrombie, Paul Barbier A. Hamilton Thompson, John Clapham, William H Bragg, Arthur Smithells, Arthur G. Perkin, Henry Procter, Henry Raper and Berkeley Moynihan al won in their time high international reputations fo themselves and for the University. Others are to near the present day to be mentioned in this review but in Part 2 of his work, entitled "Et Augebitu Scientia"—the University motto—Prof. Shimmin has, with full justice to all, sung the praise of the present and the immediate past.

But praise for achievement is due not only to the distinguished vice-chancellors and their academic colleagues, but also to those high-minded and far-seeing laymen who have given such ungrudging and helpful service in high administrative and advisory capacity; the functions and purpose, therefore, of all in the hierarchy, from chancellor, through pro-chancellor to members of council and their committees, are set out and particular personalities singled out for special mention. The reader will note with interest, perhaps, that even in the short space of fifty years the outlook and methods of these public-spirited men—often the sons of fathers who have similarly served—have changed in evolutionary manner from the firm, though kindly, autocracy of the past to the gentler advisory guidance of the present.

Many of the illustrations have been charmingly executed by Maurice de Sausmarez, head of one of the youngest University Departments, that of Fine Art; the printing, photographic reproductions and binding are quite impeccable, and the whole effect is most pleasing.

In short, this is a most interesting book, full of information about the University, historically, geographically, architecturally, numerically and financially, but nevertheless it is full also of the human and personal side of a great and continuing endeavour; it will stand as a lasting and authoritative summary of the early life of the rapidly evolving University of Leeds.

R. WHIDDINGTON

FLOWERS AND FUNGI

Wild Flowers

Botanising in Britain. By Dr. John Gilmour and Dr. Max Walters. (The New Naturalist: a Survey of British Natural History.) Pp. xiv+242+56 plates. (London: William Collins, Sons and Co., Ltd., 1954.) 25s. net.

Mushrooms and Toadstools

A Study of the Activities of Fungi. By Dr. John Ramsbottom. (The New Naturalist: a Survey of British Natural History.) Pp. xiv+306+71 plates. (London: William Collins, Sons and Co., Ltd., 1953.) 30s. net.

IT is said that every age has its book, and the book of the present age would almost seem to be a natural history book, so many are these and so insatiable the demand for them. Why this should be opens up a most interesting field for speculation, and many explanations are offered. Some think that it merely expresses the swing of the pendulum in the fashion in books; but it seems unlikely that this can be the whole story, and many prefer to think that it betokens something more than this and, especially, a growing realization that we have wandered too far from the simple and beautiful, and are now seeking, with no little nostalgia, to recapture something that is escaping us.

Whatever the truth may be, there is now an immense array of books dealing with nature study in Great Britain. They are of all sorts and sizes; but their general level is high, and in none of them more so than in the volumes of Collins's "New Naturalist Series". The list of titles here is now impressive; but that there are springs still unexhausted is well shown by two recent (though long adumbrated) additions to it, "Wild Flowers" by John Gilmour and Max Walters (No. 5) and "Mushrooms and Toadstools" by John Ramsbottom (No. 7), both of which fully maintain the standard set by their predecessors. The former is, essentially, a rather new treatment of a theme which never seems to tire, and perhaps the best compliment that can be paid to its authors, who write most pleasantly, is to say that they have succeeded in making something of their own that is distinctive. Incidentally, it should be noted with reference to p. 29 that ancient *Nelumbo* fruits from Manchuria were germinated in Britain almost thirty years ago (see *J. Bot.*, 1926). The latter book is, as essentially, a rich mine of information, both scientific and curious, about a narrower field, which, like some of the plants it contains, is something of an acquired taste, and here again the author has succeeded admirably in his task.

Indeed, if criticism is called for at all it is to be directed, in both cases, at matters of policy rather than content. "Wild Flowers" makes necessary, yet again, the strictures which have so often been passed on the inappropriate use of colour photographs in books of this kind. Surely so reputable a book should not suggest to the botanical tyro that birds-foot trefoil (Plate 12*b*) has large entire leaves, or that betony (Plate 2*b*), which is one of the strongest-hued plants in the flora, is one of the least convincing. All this, moreover, amid some very lovely black-and-white pictures. In "Mushrooms and Toadstools", where the subject eminently suits them, colour photographs are a success, and indeed may steal more of the author's thunder than they warrant; but here an unnecessary weakness is the inclusion of a chapter on penicillin, which, though vastly interesting, does not fall within the title of the book, and seems to have been put in more to tickle the public fancy than for any better reason. Nevertheless, both these books are notable additions to the literature of our countryside and remind us, once again, of the real truth in Stephen Leacock's words:

> "Surely no nobler theme the poet chants
> Than the soft science of the blooming plants".

CHEMICAL ANALYSIS OF INDUSTRIAL SOLVENTS

Chemical Analysis of Industrial Solvents

By Dr. Morris B. Jacobs and Dr. Leopold Scheflan. (Chemical Analysis Series, Vol. 7.) Pp. xxii+501. (New York and London: Interscience Publishers, Inc., 1953.) 10 dollars.

THIS book, the seventh volume in a series on chemical analysis, is a collection of methods used in the examination of solvents. The text can be divided into four sections: sampling and general physical and chemical methods; physiological effects of solvents and vapours; methods for the analysis of solvent mixtures; and the testing and determination of solvents in specific groups.

The general methods are comprehensive and include details of the determinations of specific gravity, viscosity, flash point, boiling range, acidity and iodine value, to name a few at random. The authors have drawn the description of the testing equipment and many details of experimental methods from current American specifications, and not all the tests described can be applied to meet specifications accepted in Great Britain. The section dealing with the determination of pH is perhaps unnecessarily sketchy and curtailed, and this criticism can be applied to most of the physico-chemical methods described in later chapters—polarographic methods, for example, being dismissed in one page.

The chapters dealing with the analysis of solvent mixtures cover both the chemical examination of the liquid solvents and the absorption and examination of solvent vapours. Several schemes are given for chemical identification, and a section on the determination of functional groups is included. One feels that ultra-violet and infra-red spectroscopic methods should merit inclusion in this section, since both can be very useful tools in the analysis of mixtures.

The remaining two-thirds of the book is occupied by detailed analytical procedures for specific groups of solvents. Included are aliphatic, aromatic and cyclic hydrocarbons, alcohols and polyhydroxy compounds, esters, acids, aldehydes and ketones, and solvents containing nitrogen and sulphur. Methods suitable to the general group of solvents, again mainly drawn from specifications, and detailed procedures for the determination of individual solvents are described. The use of trade names for reagents is sometimes confusing, and a mistake appears in the tests for acetic anhydride and formic acid. The general layout and binding are excellent, and the contents list and index satisfactory. References in the text are numerous, and an additional list of selected references is to be found at the end of each chapter.

The book is a most valuable addition to the library of all analytical chemists, and all concerned with the varnish and lacquer industries will find it particularly useful as a book of reference.

C. Whalley

WHAT IS KNOWN ABOUT SLEEP

Sleep

How to Get More of It. By Chapman Pincher. Pp. 120. (London: "Daily Express", 1954.) 5s.

THIS little volume will probably be added to the 3,500 titles currently listed in "How-to-Do-It Books: A Selected Guide"—books that are intended to instruct the reader in "how to do, be, become, make, or cope with something". However, in this sense, the title of Mr. Pincher's book is misleading, as it contains nothing to suggest that *more* sleep is desirable, or how to get it. Quite to the contrary, there is a chapter on "How to Stay Awake".

The eighty-odd pages of text, divided into seventeen chapters, each preceded by an appropriate humorous drawing, represent a fairly accurate digest of findings in research laboratories and hospitals, culled from "day-to-day study of technical reports from many countries". Interspersed historical and contemporary anecdotes pertaining to sleep, as well as accounts of the author's own varied experiences, in war and peace, serve to enliven an otherwise dry recital of scientific and medical discoveries. Mr. Pincher's interpretations of the latter are, unfortunately, not altogether free from contradiction an one-sidedness. Thus, in Chap. 1 ("Settling Down t Sleep"), he chooses to "plump for the side-lyin posture put forward recently as most satisfactory b Dr. James McDonnell, a London physician", usin three drawings to illustrate the one proper and tw faulty positions. Nevertheless, he admits, in the sam chapter, that "no matter what posture you adop for going to sleep however you are certain t change your position many times during the night' Evidently it makes little difference whether on goes to sleep in one position or another. Yet M Pincher states that when he directed attention t Dr. McDonnell's recommendation in a newspape several readers wrote to him "gratefully because th information had brought them more restful slee than they had enjoyed for years".

The author rightly rejects the old 'anæmia theory of sleep; but, on the basis of a reported lowerin of the degree of oxygen saturation of hæmoglobi surmises that "the brain as well as the rest of th body is subjected to some degree of oxygen starvatio during sleep" (p. 25). He further declares that "ther is no doubt that the blood-supply to the brain considerably reduced during sleep" (p. 41). As matter of fact, the brain consumes just as muc oxygen during sleep as in wakefulness (about 3·5 ml 100 gm./min.), and, as to blood flow, it is actuall *increased* some 10 per cent (from 59 to 65 ml./10 gm./min.) in sleep, due to the dilatation of th cerebral blood-vessels.

Mr. Pincher abandons his role of mere interpret of technical reports when, in Chap. 11, he propound a theory of antidromic conduction from the visu area of the cerebral cortex back to the retina as a explanation of hallucinations. That a *psychologic* projection from the brain to the visual field is involve in normal vision of real objects was convincingl demonstrated by Christoph Scheiner in 1614. hallucination, therefore, or seeing things that are n actually there, can result from cortical stimulatio (chemical, electrical, or other) that originates locall instead of in the outside world, via a retinal imag It should be admitted, however, that the gener reader will not comprehend, and so will not b harmed by, the author's excursions into the realm oxygen starvation or theory of hallucinations.

The book also deals with the physiology of wakefu ness and the diurnal variation in alertness. Many reader will rid himself of a guilt complex on learnin that Mr. Pincher found what he "had been seekin for thirty years—a medical reason for getting up lat in the morning and going to bed late at night" (p. 32 Other topics touched upon are: dreaming, snorin insomnia, sleep in animals and babies. Concernin the latter, it is not true that new-born babies slee "most of the twenty-four hours", and that sleep reduced to eighteen hours at three months and seventeen hours at six months (p. 101). Recentl published figures show that the average baby slee only about fifteen hours at birth and less than fou teen hours at the age of six months.

Summing up: when he is not venturing beyon his eruditional depth, Mr. Pincher does an excelle job of popularizing science. Disregarding th 'howtoism' of its title, and considering the univers interest in the subject-matter, the book will be foun both instructive and entertaining. It can be recon mended to the non-scientific reader as one of th better written accounts of the nature of sleep ar wakefulness.

N. Kleitman

RICE SUBSTITUTES

By V. SUBRAHMANYAN, D. S. BHATIA, M. SWAMINATHAN and G. S. BAINS
Central Food Technological Research Institute, Mysore

DURING the past few decades, there has been a steady deterioration in the overall food position f many of the east and south-east Asian countries. The total production, chiefly of food-grains, has undoubtedly increased; but the demand from the apidly growing population has increased to a greater xtent. As the result of this, countries like India have steadily changed from the position of exporters o that of importers of food-grains. The population of India has been increasing at an average of 1·35 per cent[1] a year and that corresponds to about 4·5 million a year, at the present time, with the prospect f increasing to a higher figure in the years to come. A large section of the population are rice-eaters, and s this grain is in great demand, the prices have been steadily rising, though, during 1953, owing to an xceptionally favourable season throughout the region, the export price from surplus countries like Burma came down from about £80 to about £60 per on. It may be reasonably expected that the price will tend to rise again. Unless the consumers change to other types of food-grains, there may even be a ice famine in the years to come.

As a bulk food material, rice has certain unique properties, which are not shared by other food-grains. It has a neutral taste and flavour and can be consumed as a savoury or a sweet dish. It is easily cooked and digested. Having become accusomed to such a soft and almost fibreless grain, the average rice-eater will not readily change over to any other food material which does not possess imilar properties. In fact, attempts made in India to popularize wheat, jowar or maize among rice-eaters have not been successful. Provision of a substitute for rice has therefore become one of the major food problems not only for India but also for he whole Asian rice region, which holds more than half the population of the world.

Processing of Grains and Tubers

One of the earlier attempts in the field was that of Bhatnagar, who carried out investigations on the reconstitution of broken rice, as obtained during milling, into whole rice. During recent years, attempts have been made to process other grains so as to give them the shape and cooking quality of rice. Thus, wheat, barley and maize have been processed, and some brands like 'Ryoena', 'Barley-rice' and Nor-ice' are already on the market. During the war years, wheat semolina was processed to produce different brands of 'mock rice'. Potato rice is still being produced in Holland. Such rice substitutes require the appropriate starting materials, which are not themselves being produced in sufficient quantities n the south-east Asian countries. If the deficit countries are to meet their own requirements, alternative sources, which can be plentifully and cheaply produced in the same region, will have to be found.

Processing of Blends

Since 1949, the Central Food Technological Research Institute, Mysore, has been engaged on the study of the possible utilization of cheap and abundant food materials which are naturally rich in starch and protein, so as to obtain, by suitable blending, a composition and nutritive value approximating to that of rice. After trying hundreds of such blends, it was found that a combination of tapioca (*Manihot utilissima*) and groundnut flours would make a cheap and satisfactory blend. *Manihot* grows well on even comparatively poor soils, and the yield of root, on a dry basis, is at least 3–4 times as much per acre as in the form of any food-grain. When both the outer skin and the inner rind are removed, the residue, on drying, yields an attractive white flour which, though mostly starchy, still contains useful quantities of minerals, especially calcium. Goundnuts can be skinned after gentle roasting or other treatment. The oil can be mostly removed by the expeller or solvent extraction. The residue yields a pale yellow, attractive flour containing about eight times as much protein as milled rice. If the groundnut kernels are carefully selected, the flour keeps well for several months. Both tapioca and groundnut flours, between them, contain more of the essential minerals and vitamins than natural rice. By combining tapioca and groundnut flours in the proportion 85 : 15, a product with an overall nutritive value which was somewhat higher than that of rice was obtained.

The technological aspects of converting such a blend into a grain like rice offered the maximum difficulty. Like other root starches, tapioca starch tends to cook to a translucent and sticky mass. Groundnut protein, especially as present in the flour, has no binding power. It was found, however, that on treatment with 40–50 per cent by weight of boiling water, the starch in the mixture (chiefly that of tapioca) becomes sufficiently gelatinized to yield a satisfactory dough. The dough could be extruded under pressure; but as the resulting product did not possess good cooking properties, further improvements in the composition had to be made. It was found that the addition of 1·5 per cent of karaya gum (*Sterculia urens* Roxb.) improved the quality of the dough and generally the body of the cooked product. Further improvement was introduced by the addition of 1 per cent alkali-digested corn cob. This material tended to harden the grain. Addition of 0·3 per cent of stearic acid made the grain somewhat opalescent and improved its individuality. The colour of the finished product was distinctly improved by the incorporation of 0·04 per cent alkali bisulphite. All the above-mentioned products may be added together as a mixture at the time of the preparation of the dough. The resulting grain, as obtained through an extruding press fitted with the rice die, was quite attractive and comparable in appearance with that of certain brands of natural rice. The product required, however, certain further improvements so as to make it acceptable to the consumers.

In India, as also in most other parts of Asia, the average housewife washes the rice before cooking because the usual bazaar product contains much dust and dirt. Like the usual macaroni products, the extruded grain as prepared above tended to break

up on being washed and rubbed with cold water. On cooking, it was found that there was heavy gruel loss which, again, would not be acceptable to consumers. The cooked grain was also a little too soft to the bite. It was necessary, therefore, to introduce further improvements in the processing. It was found that, on heating to a temperature of 110–120° C. for even a few minutes, the starch of the blend, and particularly that of tapioca, changed in character and that the individuality of the cooked grains was fairly well preserved. Gruel loss was also reduced to a minimum. Further improvement was effected by spraying a thin coat of calcium caseinate (calcium oxide : casein = 1 : 20) on the finished grain. Even a thin coat corresponding to 3–4 per cent by weight made the grains fairly resistant to water. They could be washed and rubbed under water for 4–5 min. without any appreciable loss. The coat also improved the cooking quality, and the cooked grain had a feel and taste corresponding to that of slightly parboiled rice. It was also found that incorporation of wheat flour to the extent of 20 per cent greatly improved the quality of the dough and the finished grain. In fact, the use of chemical improvers can be largely dispensed with if some wheat flour can be incorporated in the mixture.

Factory Trials

With the above as the background, factory trials were carried out in the United Kingdom and later in Switzerland. Messrs. Buhler Brothers, of Uzwil, took a keen interest in the effort, and fabricated the necessary additional equipment for large-scale processing. The procedure which was finally followed consisted in feeding the flour blend through the conveyor and then running boiling water in a steady stream into the mixing and kneading tank. The resulting dough was then drawn into the extruding press, where it was forced under pressure through a rice die provided with the usual mechanical cutter. The grain which came out, in a steady stream, was then subjected to a preliminary, and then a final, drying. As the grain does not crack on heating, it was found that the temperature could be readily raised to about 120° C., so that the drying could be speeded up. The same heating chamber also served to condition the grain so that both the operations were combined in one. In semi-large-scale operation, heating for about 2 hr. at 120° C., combined with air circulation, serve to dry the grain and at the same time to condition it. The finished grain thus obtained was subjected to spraying with a thin suspension of calcium caseinate, steamed and the dried in a blast of hot air. This helped to dry off th coat almost as quickly as it was formed and thu discouraged the tendency to form lumps. Mechanica agitation during spraying was necessary.

Properties and Nutritive Value

The finished grain, thus obtained, has the appearance of slightly undermilled rice. It is best cooke by being dropped into boiling water, and the cookin time is 5–6 min. as compared with about 20 min required by raw, milled rice. The cooked produc has the taste corresponding to that of certain brand of rice, as sold in the Indian market. Consume trials have shown that the product is acceptable t rice-eaters.

Animal experiments with the product showed tha the overall growth-promoting value is more tha twice that of a good variety of rice. The produc has been given the name 'synthetic rice', in keepin with the name 'synthetic diet' which is used b nutrition workers for blended diets composed of th various food ingredients.

The raw materials, including all the accessorie would cost the equivalent of about Rs. 350 per ton The entire processing cost, including labour, supervision and depreciation, would amount to Rs. 50–6 per ton. In the early stages, the cost would naturall be high; but with the continued working and on big scale, it would eventually come down. Allowin for incidentals, the product can be marketed at abou Rs. 500 (less than £40 or 100 dollars) per ton. Eve at this price, it would be distinctly cheaper tha rice. With further experience, and on continue large-scale production, the cost can be furthe reduced.

The potentialities of such a product can be easil envisaged. With a given area of land, and wit much less attention, we can obtain 3–4 times a much of the starting materials as can be obtained i the form of any food-grain. This will be of grea advantage to the densely peopled countries, wit heavy pressure on land. The second, and a mor important, feature is the nutritive value. The product as prepared by the Mysore workers, has about twic the nutritive value of rice; but it can be stepped u to a still higher level if so desired. Considering th low level of nutrition in most of the tropical countrie and especially in the rice-eating region, there is very strong case for using synthetic rice either b itself or as a supplement in the dietary of th people.

Japanese Production

The researches conducted at Mysore have been published[1-10] in the form of short notes and papers which have appeared during the past three years. Numerous popular articles and pamphlets have also been published. During 1952, the Japanese manufacturers, who have also been keen on the search for rice substitutes, started production, using blends of potato starch, wheat flour and rice flour for their composition. The underlying principles are practically the same as those of the process adopted by the Mysore workers. The Japanese have also adopted the same English name, 'synthetic rice', for their product, and the Japanese name is 'zin-zomai'. It should be said to the credit of the Japanese that they were quick in taking up the manufacture. During 1952–53, the reported production is stated to have been about 100,000 tons. The price of the Japanese product appears to be fairly high; but there is no doubt that it will eventually be reduced. Further improvement in nutritive value is needed, and this can be achieved by adding a concentrated proteinaceous material along the lines indicated by the Mysore workers.

The relative chemical compositions of some of the rice substitutes as compared with natural rice is given in Table 1.

Outlook for the Future

Judging from the present trends, there is every indication that the rice production in the east and south-east Asian countries will not be able to cope with the increasing demands of the fast-growing population. A product like synthetic rice is bound to find a growing demand, and in the course of the next few years we may reasonably expect to see the production rise to a few million tons per annum. With further improvements in the composition and the technology of processing, better and cheaper grains could be produced. The nutritive values of the products can also be maintained at a distinctly higher level than that of natural rice.

There are already a number of rice substitutes on the world's market. They are made from different raw materials and they have varied compositions. Most of them are being marketed under proprietary names and selling on their own merits. It is expected that, in course of time, several more such products will be marketed. It will soon be necessary to discuss the composition of such products and to lay down specifications on an international basis; the Food and Agriculture Organization can usefully take the initiative in this direction.

There are three broad lines of food production. The first one is that of increasing the production from land, water and other sources. Improved methods can easily raise the world's production by 25 or even 50 per cent, though it will be extremely difficult to ensure a uniform application of such methods all over the world. The second method is that of converting the vast and abundant sources of second-grade food materials, by suitable blending, into first-class articles of food. Production of synthetic rice will come in this category. Products like sugar from cellulose, food yeast, food-stuffs from seaweeds and other algae will also come in the same category. The possibilities in this direction are very considerable. The third method, which is still a dream of chemists, is that of synthesis from elementary materials. Unlike the fixation of nitrogen, the fixation of atmospheric carbon dioxide is going to be rather difficult because of the low concentration of this gas in the atmosphere. For a long time to come, the world may have to depend on the processing of coarse and low-grade food materials, which are fortunately still abundant, and their conversion into first-grade articles of food. Production of synthetic rice is a beginning in this direction; but bigger and more important developments are bound to follow in the years to come.

RHEOLOGY IN MECHANICAL ENGINEERING

RHEOLOGY is regarded by some as a specialized activity concerned with the description of the response to mechanical stress of those categories of matter the behaviour of which cannot, even approximately, be described as Newtonian flow or Hookean deformation. Others view the subject more broadly as that branch of the science of applied mechanics which is concerned with the deformation and flow of matter generally. The membership of the British Society of Rheology embraces both those who specialize in the subject and those chemists, physicists and engineers, mainly engaged in applied science, whose work involves a knowledge of deformation or flow of matter and who find in the Society common ground for the development of this interest. It is to these latter that the recent conference of the Society held at the Mechanical Engineering Research Laboratory (Department of Scientific and Industrial Research), East Kilbride, during June 10–12 will have had the most appeal.

This Laboratory, which has assumed responsibility for a large part of the research formerly pursued in the Engineering Division of the National Physical Laboratory, is organized in seven divisions as follows: properties and strength of materials; mechanics of solids, stress analysis and vibration; mechanics of fluids, including hydraulic machinery; lubrication, wear and corrosion; mechanisms and engineering metrology; mechanics of formation and machine shaping of materials; heat transfer and applied thermodynamics. It will be apparent from this list of activities that the deformation and flow of matter enters very much into the work of the Laboratory, and the opportunity afforded to participants to inspect work in progress was a valuable feature of the conference.

In view of the importance of metals as materials of construction for machinery, it is not surprising that the predominant interest in the conference was the flow of metals. Thus the first paper, by Dr. J. F. W. Bishop (East Kilbride), was on the relationship of certain properties of metals to their crystal structure. Phenomena associated with metals were divided into three classes—macroscopic, microscopic and atomic—and the relevance of investigations at one of these levels to phenomena associated with a different level was discussed. Dr. Bishop summarized the salient features of three types of lattice structure commonly occurring in metal crystals and described their mechanism of deformation, stressing those structures which are able to accommodate an arbitrary strain by relative sliding of atomic planes. Applications of the Bishop–Hill theory of crystal distortion as generalized for aggregates were described and discussed in relation to experimental evidence.

Mr. H. Ll. D. Pugh (East Kilbride), in his paper on current problems and experiments on time-independent plastic deformation, dealt with the fundamental plastic properties of materials, such as yielding under combined stress, hardening and the effects of hydrostatic pressure. In the absence of a general solution of the equations governing plastic flow, their simplification for the special cases of plane stress and plane strain is necessary to enable certain engineering problems to be attacked. Strip drawing, extrusion and certain machining operations resolve themselves into steady-state problems, while indentation becomes a yield stress problem. Theoretical and experimental results were compared for extrusion and for indentation with flat smooth rigid dies.

Mr. F. Ellis and Prof. H. Ford (Imperial College of Science and Technology, London) discussed strip rolling as a steady-state process. An approximate theory was outlined by Prof. Ford, who described subsidiary experiments to determine the yield stress–strain characteristics of the strip material. Coefficient of friction between roll and work was estimated from rolling experiments in which varying amounts of back tension had been applied. Mr. Ellis described experiments wherein the data required to plot the slip-line field were obtained from the measured distortion of a network of lines engraved on a surface lying in the plane of flow. This technique was complicated in its application to rolling by forces in the plane of the sheet which would cause two unattached sheets placed side by side to separate. The difficulty was overcome by a specially developed method whereby the edges of two sheets could be welded together after the reference lines had been engraved on them.

In contradistinction to the two previous contributions, which were directed towards the elucidation of situations wherein it was desired to cause flow as part of a manufacturing process, that by Dr. A. E. Johnson (East Kilbride) on the behaviour of metals under complex stress at high temperatures was concerned with the small unintentional flow or creep of metals used for the construction of boilers, turbines, etc., that are required to operate at high temperatures. Where such parts are subject to combined stresses, designers have previously been obliged to rely on experimental data obtained from simple stress tests and adjusted by doubtfully valid theory. Dr. Johnson described a comprehensive research into the complex stress, creep, plastic strain and relaxation properties of some typical technical materials. At lower stresses the materials were shown to follow the St. Venant–Von Mises creep-rate relations and to remain isotropic; but at higher stresses the strained material becomes anisotropic, which necessitates modification of the equations.

Fatigue failure of metals may be regarded as rupture rather than a flow phenomenon, but some work sponsored by the Mechanical Engineering Research Laboratory and described by Mr. N. Wadsworth (University of Bristol), in a paper on observations of energy dissipation during high-speed fatigue tests revealed the occurrence of an increasing number of slip bands during the progress of a fatigue test During the early stages of a test, the rate of energy dissipation in the material fell to a low value and then increased until failure occurred. This increase was dependent on stress, and a strong correlation between this rate and fatigue life was revealed. Annealing at intervals during the test appeared to remove the effect of previous stressing on energy dissipation, but did not affect life. This threw doubt on the significance of the observed correlation, and Mr. Wadsworth concluded with the suggestion that the first irreversible change leading to the formation of cracks must have occurred very early in the fatigue test.

A more general approach to rheological problem was represented by a contribution from Dr. P Feltham (Standard Telecommunication Laboratories on the laws of stress relaxation and creep in solids Remarking on the qualitative similarity in the response of solids of widely different structures to applied stresses, particularly in creep and relaxation, Dr Feltham sought an explanation in the nature of flow itself rather than in the study of detailed atomic o molecular structure. A given solid can be assumed to possess 'relaxation centres' having approximately the same heat of activation but, on account of variations such as shape and size, having different configurational entropies of activation. Assuming norma distribution of relaxation times it is possible to derive a relaxation curve common to many solids. Experimental data selected from published work relating to aluminium, rubber, plastics and ceramics were shown to be in good agreement with the theory. Dr. Feltham regards Nutting's Law as approximating to more general laws over sufficiently wide ranges of the variables to be of practical use in the presentation o experimental data.

The fact that mechanical engineering science is by no means confined to the behaviour of solids was exemplified by a paper by Mr. E. J. Le Fevre (East Kilbride) which dealt with some developments in the theory of viscosity. The importance of the viscosity of gases in the study of the transfer of heat by convection is obvious; but availability of experimenta data covering this quantity over the range required is restricted, and discrimination is necessary in assessing its accuracy. Mr. Le Fevre showed how viscosity data relating to those fluids which satisfy the principle of corresponding states can be correlated in terms of reduced variables. It was shown that, with few exceptions, the viscosity of gases can be predicted within about 5 per cent from knowledge of the three critical constants. This result was considered relative to the kinetic theory and was shown to be deducible from combination of the Lennard-Jones and Devonshire theory of the critical state with the calculations of Kihara and Kotini. The Sutherland model was shown to be inconsistent with experiment

Many problems of fluid motion in the mechanical and chemical engineering industries are amenable to solution by models, and Mr. W. J. Robinson (East Kilbride), in his paper on some fluid-motion problems, exemplified useful applications of this technique at the Mechanical Engineering Research Laboratory. Advantages are offered by substitution in a model of gases for liquids or vice versa. The conflicting requirements of the laws of similitude complicate the design of experiments, and a plea was made for the publication of more experimental data to provide a basis for evolution of rules to govern the 'scaling-up' of model performance. Increases in the duty required to be undertaken by modern hydraulic machinery have caused a marked increase in the incidence of cavitation, and Mr. Robinson discussed the influence of the properties of the liquid itself and the presence of nuclei on cavity collapse and noise. Methods for estimating flow losses with non-Newtonian liquids require development. The pumping of raw peat and measurement of the flow of blood to and from the human heart provoked a lively discussion.

Lubrication has been defined as the reduction of friction and wear between rubbing surfaces by interpolation of substances which offer resistance to the normal forces pressing the surfaces into contact and yet are capable of being deformed easily in a tangential direction. It is obvious that the rheological properties of lubricants are of interest to engineers concerned with running machinery, and Dr. F. T. Barwell (East Kilbride), in a contribution on lubrication from the rheological point of view, outlined some of the considerations governing boundary and hydrodynamic lubrication. Further understanding of the mechanism of wear is dependent, among other things, on an understanding of the rheological behaviour of material in the surface regions of components suffering damage. Examples were given of those forms of wear known as abrasion, scuffing and pitting, and the potentialities of radioactive tracer methods for the study of wear were discussed.

THE ROYAL NETHERLANDS METEOROLOGICAL INSTITUTE (1854–1954)

THIS decade is one of centenaries in the meteorological world, for official meteorological activities started in many countries around 1850. The Royal Netherlands Meteorological Institute, now at De Bilt near the town of Utrecht, was established in 1854 and celebrated its centenary this year on January 31. As part of the celebrations, a substantial memorial volume has been prepared*, in which the history of the Institute is portrayed in word and image.

Meteorology in the Netherlands did not start in 1854; there are many signs of earlier activity in the form of long series of observations, admirably compiled by Labrijn. As everywhere else in the world, these observations were made at universities, or by organizations and persons especially interested in meteorology; and looking at the state of affairs in 1854, one should realize that the famous American naval officer, Maury, prior to that year, had already collected many meteorological observations from oceanic areas.

In the Netherlands it was important for the development of the subject that Buys Ballot, chemist, mineralogist, mathematician and physicist, became fascinated by meteorological problems, and that he, in his position as university professor, created an observatory in Utrecht. Late in 1853 Buys Ballot convinced the Government that "there was a future in the establishment of a Meteorological Institute" and early in 1854 his observatory was converted into the Koninklijk Nederlands Meteorologisch Instituut. Buys Ballot was the first director of the Institute and aimed very high. Translated freely, his programme was formulated by the words: "As a result of the methods we have adopted—namely, to collect observations from some well-selected points abroad and to study the deviations from the normals at these points—the Institute pursues a higher object than any other existing institute. Day after day it deals with the most important questions in meteorology, the solution of which was already some years ago vaguely indicated by Dove for monthly periods. Utrecht will become the central observatory for Europe. Already nowadays the weather and its changes over the greater part of Western Europe are being closely followed and studied".

The early period of Buys Ballot's directorship was one of great activity. It was the time of Dove in Germany, Espy in the United States, FitzRoy in Britain and LeVerrier in France. It was also the time in which meteorologists suddenly became aware that weather forecasting might develop into a reality as a result of the invention of the electric telegraph. Great discoveries were made: Buys Ballot announced one of them in the form of four propositions during a meeting of the Netherlands Academy of Sciences (October 3, 1857), and it was on the basis of these four propositions that later on the famous wind law of Buys Ballot was formulated. Weather maps, though rather primitive, were drawn by Buys Ballot on a routine basis, and a gale warning service was established in 1864. Internationally minded as he was, Buys Ballot copied the system of signals already in use in Britain; but when the British service was discontinued in 1866, he felt free to develop the 'aëroclinoscope', a new design to indicate forthcoming gales to sailors. The aëroclinoscope was a signal post, which showed the direction and value of the pressure gradient over the Netherlands. Its indications had therefore to be interpreted by the users, who had to have a thorough idea of Buys Ballot's law. This might be one of the reasons why the Dutch merchant marine became so early thoroughly interested in meteorology and assisted the Institute in building up an enormous amount of material, gathered from almost every ocean.

It is worth noting that Buys Ballot needed continuous registration of the pressure values at several stations in order to be able to follow the gradients closely. The first electric telerecorders, precursors of our radiosondes, were then developed and for some time serious efforts were made to record at Utrecht the pressure values at Flushing during the night hours. The technical difficulties appeared to be very great, and finally the efforts were given up. It is still, however, customary in the Dutch synoptic service to compute the pressure gradient in various triangles over the Netherlands on an hourly routine basis.

Buys Ballot needed uniform observations for the successful realization of his programme. The well-known international congress in Brussels (1853), which was initiated by Maury, created a certain uniformity in maritime meteorology; over land, however, observations were made at different times, with different instruments in varying exposure. The difficulties resulting from the lack of generally accepted rules inspired Buys Ballot to write a treatise entitled "Prière à tous ceux qui veulent bien de la météorologie" (1856). But it was only sixteen years later that Buys Ballot opened the first international meteorological congress at Leipzig and became the first president of the International Meteorological Committee and the real father of international meteorology. Dutch meteorologists continued to play important parts in the international meteorological world; Van Everdingen guided the International Meteorological Organization during 1923–35, and Cannegieter was the first chief of the permanent secretariat of that Organization.

---

* Koninklijk Nederlands Meteorologisch Instituut 1854–1954. Pp 460+74 figs.+4 coloured plates. ('s-Gravenhage: Staatsdrukkerij en Uitgeversbedrijf, 1954.)

The Institute lost its great leader in 1890, and with his decease an era of steady development came to an end. Meteorology entered, not only in the Netherlands but also elsewhere, a rather dull period which started with "the disappointment of the nineties". New horizons were opened around 1910, with the beginning of upper-air observations. Van Everdingen, director since 1905, started his activities as extra-ordinary professor at the University of Utrecht with a lecture entitled "The Third Dimension in Meteorology". A theodolite for recording the projections of pilot balloon-tracks was developed, kite ascents were made, and many Dutch meteorologists had licences as free-balloon pilots. Cannegieter was the first who experimented with aeroplanes as meteorograph-carriers, and the regularity of the Netherlands upper-air ascents became known all over the world. When a new field was opened with the introduction of the radiosonde, Cannegieter used the instrument on an expedition to the Azores, from where no upper-air information had previously been obtained, and also in Iceland during the second Polar Year.

When Van Everdingen took the reins, the Institute, which had moved from Utrecht to De Bilt in 1897, consisted already of five divisions. It was then, and still is, really a geophysical institute, the activities of which are not limited solely to meteorology. With the development of the geophysical sciences during the course of the past half-century, the divisions slightly changed their names, but there are still those of forecasting (now combined with aeronautical meteorology), climatology (now combined with agricultural meteorology), maritime meteorology (now combined with oceanography), seismology and magnetism (now also deeply involved in ionospheric research) and finally a general service division (administration, library, workshop and instrument development). Each division is headed by a director (a specialist in his own field), and in Van Everdingen's time the director in chief was still an all-round meteorologist.

Cannegieter guided the Institute through the unhappy period of the Second World War, when forecasting for the general public and for aeronautics was curtailed, and synoptic and aerological observations were totally stopped. In spite of all material and other difficulties, the war period provided some dividends, as the synoptic staff took part in an extensive magnetic survey of the Netherlands, thorough plans could be made for future development and serious scientific investigations improved the knowledge of the forecasters who were perforce idle during this period.

Thus came the post-war period, with its stormy development in the Institute's activities and the enlargement of its field of action. Cannegieter, who had already passed the retiring age, was succeeded by Vening Meinesz, a geophysicist of renown who had already long relations with the Institute, where, among others, his apparatus for gravity measurements at sea had been built. From 89 men (24 scientists) in 1945 the personnel jumped to 345 (73 scientists) in 1954. The greatest growth took place between 1945 and 1950. It was no longer feasible to house all the workers stationed at De Bilt in the old building. Offices were spread all over the village. The disadvantages of this involuntary decentralization were felt almost daily. Vening Meinesz's ambitions to bring the Institute again under one roof were, in spite of all difficulties, realized in 1953, when new wings to the old building came into use. The floor space of approximately 1,000 m.^{2} was increased to 3,500 m.^{2}, and, in addition, a plot of 2 hectares was joined to the gardens, sufficiently large for investigations in the field of agricultural meteorology and for the launching of radiosondes in spite of the fact that the aerologists are close neighbours of the ionospheric transmitter with its high antennæ.

Vening Meinesz found himself too much absorbed in administrative duties and returned to science again in 1951, at the moment when, according to his views, the staff was sufficiently large to deal with its practical and scientific tasks, and when his plans for the extension of the premises were accepted by the Government. He was succeeded by the present director, C. J. Warners, a former Secretary of State in the Netherlands East Indies.

The Royal Netherlands Meteorological Institute is an entity in the economic life of the Netherlands, not only because of its forecasts for the general public, agriculture and horticulture, fisheries, shipping and aviation, but also because of its activities in so many other fields. It has relations with agricultural research, through an active group of agricultural meteorologists. With those interested in the water balance of earth and atmosphere, it studies evaporation and related processes. A group of statistical workers has already solved many practical problems. The maritime meteorologists, up to now engaged in the construction of the atlases for mariners, have diverted their interests in a scientific direction. Oceanographers pay much attention to high tides and storm surges in the North Sea, but do not neglect other problems of a local nature. New ideas about microseisms have developed in the seismology division, and the telegraph authorities keep close contact with the workers in the fields of magnetism and ionospheric research. These are but a selection of the many topics in which the Institute is interested, all of which are faithfully recorded in the recent centenary volume.

W. Bleeker

OBITUARY

Mr. F. Morley Colebrook, O.B.E.

During his thirty-three years service on the scientific staff of the National Physical Laboratory, Mr. F. M. Colebrook, who died on June 21, played a major part in the development of the Radio Division from its birth as a section of the Electricity Division, and more recently became the head of the newly formed Electronics Section.

Colebrook was born in March 1893 and studied science at Birkbeck College, University of London. After service in the First World War, he continued his studies at the City and Guilds Engineering College, obtaining his A.C.G.I. and B.Sc.(London) and, after some research on high-frequency resistance, his diploma of the Imperial College (D.I.C.).

He joined the National Physical Laboratory in 1921 and soon demonstrated his flair for carrying out a combined theoretical and experimental investigation of various fundamental problems in the radio field. He soon made distinctive, and very practical, contributions to our knowledge of the characteristics of transmitting and receiving aerials, to the development of radio-frequency valve amplifiers, the technique of the precise measurement of current and field-strength at high frequencies and the definition and measurement of interference. He was responsible for the publication of several special reports of the Radio Research Board, outstanding among which is the one entitled "A Theoretical and Experimental Investigation of High Selectivity Tone-Corrected Receiving Circuits". This work, published in 1932, did much to clear the minds of those responsible for the allocation of frequencies for broadcasting and communication services, at a time when confusion of thought made the 'physical reality of sidebands' a subject of serious discussion among certain authorities. Many other papers were contributed to the *Journal of the Institution of Electrical Engineers*, and to the *Wireless Engineer*, of which periodical he later became a member of the editorial advisory board. He was the author of two books on "Alternating Currents and Transients" and "Basic Mathematics for Radio Students".

On technical committees, as in his laboratory work, Colebrook displayed that outstanding characteristic for starting a penetrating inquiry into matters which had often already been accepted by others, and so bringing to light sometimes a fallacy, and at other times a new and refreshing point of view. As a colleague, he was delightful to work with, and he could be relied upon to produce a novel, if sometimes idealistic, point of view on any new problem; he was always ready to be consulted. I was indeed sorry when, with the formation of the Radio Research Organization, Colebrook was destined to sever his formal association with radio matters and become the leader of the separate team formed at the National Physical Laboratory to develop, into a practical working machine, the mathematician's conception of an automatic electronic computor.

Apart from his work, Colebrook was a man of many tastes. He read voraciously and widely, he had a keen ear for music, and with the aid of a high-fidelity receiver of his own design and construction, he seemed to listen to and enjoy every worthwhile musical broadcasting programme. He had a lively interest in amateur dramatics; he was a keen gardener, and, under the necessities of wartime, took a practical and utilitarian interest in the breeding of rabbits.

It is to be regretted that he was not spared to develop and enjoy these personal and unofficial activities, or even to be invested with the O.B.E., to which he was appointed in June last.

R. L. SMITH-ROSE

NEWS and VIEWS

Chemistry at the Imperial College of Science and Technology: Prof. H. V. A. Briscoe

AFTER an association with the Imperial College of Science and Technology extending, with one intermission, over a period of forty-eight years, Prof. H. V. A. Briscoe now relinquishes the directorship of the laboratories for inorganic and physical chemistry at the College, and retires from his chair of inorganic chemistry in the University of London. Entering the College as a student in 1906, he served after graduation as research assistant to the late Sir Edward Thorpe and afterwards was a member of the teaching staff of the Chemistry Department. In 1921 he was appointed to the chair of inorganic and physical chemistry in Armstrong College (now King's College) at Newcastle upon Tyne, in the University of Durham, succeeding the late Sir Norman Haworth four years later as head of the Chemistry Department. In 1932, however, he returned to the Imperial College to follow Prof. H. B. Baker in the chair of inorganic chemistry, and on the retirement, four years later, of Prof. J. C. Philip, assumed the direction of the laboratories for inorganic and physical chemistry.

Throughout an active academic career Prof. Briscoe has also devoted much attention to researches of industrial importance; he was one of the founders of the Northern Coke Research Committee and has served as president of the Research Association of British Paint, Colour and Varnish Manufacturers. He has also participated in a study of the part played by dangerous dusts in the causation of silicosis and similar maladies. In recent years, Prof. Briscoe has taken much interest in the organization of training for laboratory service, and is now chairman of the National Joint Committee on Recruitment and Training of Science Laboratory Technicians.

Prof. R. M. Barrer

THE chair of physical chemistry at the Imperial College of Science and Technology in the University of London, formerly occupied by the late Prof. J. C. Philip, has now been filled by the appointment of Prof. R. M. Barrer. A graduate of Canterbury University College, Christchurch, New Zealand, Prof. Barrer held an 1851 Exhibition Scholarship at Clare College, Cambridge, afterwards being appointed to a research fellowship. During 1939–46 he was head of the Chemistry Department at Bradford Technical College. In 1946 he left Bradford to take up an appointment as reader at Bedford College, University of London. Since 1949 he has occupied the chair of chemistry in the University of Aberdeen, where he has gathered around him an active school of research in physical chemistry, particularly in those branches of the subject concerned with adsorption, diffusion, and the physicochemical properties generally of permeable materials, especially zeolites.

Physiology at Queen Elizabeth College: Prof. J. A. C. Knox

DR. JOSEPH ALAN CRUDEN KNOX has been appointed to the chair of physiology tenable at Queen Elizabeth College (University of London) in succession to Prof. J. Yudkin, who has become professor of nutrition in the College. Prof. Knox was born in 1911 and was educated at Aberdeen Grammar School and Glasgow

High School. He studied medicine in the University of Glasgow and graduated M.B., Ch.B., in 1935 and M.D., with honours, in 1948. In 1936 he was appointed demonstrator in histology in the Department of Physiology at Glasgow; and in the same year became assistant to the professor of physiology, the late Prof. E. P. Cathcart. He became lecturer in physiology in 1940, and four years later was appointed to a similar post at King's College, University of London, where he became senior lecturer in 1948 and adviser of studies to the Medical Faculty in 1953. Prof. Knox has published work on the effect of exercise upon the heart-rate, based upon very accurate methods of counting. During the Second World War he worked with Dr. D. P. Cuthbertson on the effect of analeptics on fatigue. More recently, he has been interested in the electro-physiology of isolated muscle and its response to denervation. He has had very wide teaching experience both in Glasgow and in London.

Philosophy at the University College of North Staffordshire: Prof. A. G. N. Flew

Mr. Antony Garrard Newton Flew, lecturer in philosophy in King's College, University of Aberdeen, has been appointed to the chair of philosophy in the University College of North Staffordshire in succession to Prof. W. B. Gallie. Prof. Flew was educated at Kingswood School, Bath, and was State Scholar in Japanese at the School of Oriental and African Studies in 1942, afterwards being attached to the Air Ministry in the Intelligence Section. He went to Oxford in 1946, taking a first in Greats in 1947, and was awarded the John Locke Scholarship in Mental Philosophy in 1948. He was then appointed lecturer in Christ Church, Oxford, before going to King's College, Aberdeen, in 1950. Prof. Flew has a considerable interest in adult education and has conducted many courses for the Workers' Educational Association and Service groups as well as broadcasting. His main studies lie in the notions of personal identity, survival and immortality, which have led him to a philosophical consideration of psycho-analysis and psychic phenomena. An enthusiastic mountaineer, Prof. Flew takes to his new post at North Staffordshire an energy and zeal which augur well for the rapidly developing school of philosophy in the College.

Development of Canada during the Past Few Decades

Addressing the Parliamentary and Scientific Committee on June 3, Dr. C. J. Mackenzie, president of the Atomic Energy Control Board, Canada, reviewed the fundamental political and economic changes which science and technology have made in Canada since 1918. He thinks that there is a substantial basis for Canada's prospects and prosperity. Since 1939, the population of Canada has increased from eleven to fifteen million, while the net income has doubled and government expenditure and foreign trade increased four-fold. Only 14 per cent of Canada's capital now comes from outside. Referring to the development of the National Research Council, formed in 1916, Dr. Mackenzie said that in 1939 it employed three hundred people, and there was a large reserve of well-trained research scientists. After the Second World War the Council undertook military and atomic energy research and now has six thousand employees. In agricultural research Canada spends 25–30 million dollars a year, or more per capita than any country in the world; Canada is now, and will remain, an industrial nation of the first rank. In reply to a question, Dr. Mackenzie said that since 1939 the National Research Council has lost only one senior man, and he knows of none who has left to go to the United States since 1946. In general, Canada has a surplus of research scientists; but more people are going from Britain to Canada than are going from Canada to the United States. Attention may also be directed to the article on the conference on "Canada's To-morrow" on p. 212 of this issue.

Commonwealth Conference on Human Problems in Industry

At a recent meeting, at which H.R.H. The Duke of Edinburgh, patron of the Industrial Welfare Society, presided, it was decided that a Commonwealth and Empire Conference should be held in Britain (probably at Oxford) during July 1956. The purpose of the Conference will be to bring together representatives from the Commonwealth and Empire who would pool their knowledge and experience of the human problems of industry in their own countries. It is intended that the age of the delegates should normally be between twenty-five and forty. The Conference will deal with the human factors in industrialization as a whole: on one hand the personal factors of the health, satisfaction, effectiveness and well-being of those working in industry; on the other, the social problems arising from the effects of industrialization on the lives of individuals, their families and communities. There is no suggestion that there should be consideration and discussion of the formal relationships between employers and trade unions, covering wages, conciliation and arbitration machinery, etc. Committees are to be set up to explore various aspects of the Conference, and a small steering committee, under the chairmanship of Sir Harold Hartley, was appointed to co-ordinate the work of the other committees. Further particulars can be obtained from the Industrial Welfare Society, 48 Bryanston Square, London, W.1.

Division of Man-made Fibres, University of Leeds

From October 1955 the Department of Textile Industries of the University of Leeds will consist of two Divisions—the present Wool Division and a new Man-made Fibres Division. Good progress is being made with the new building for the Man-made Fibres Division, which is situated in University Road, opposite the present Department. The building will cost £267,000, towards which a donation of £60,000 has been made by Courtaulds, Ltd., and £40,000 by an anonymous donor. It consists of four floors, the first floor being the most important as this will contain the pilot plant for the production of all present-day types of man-made fibres, machines for processing various fibres, looms and knitting machinery. The ground floor will contain the dyeing, printing and finishing sections and also two humidity rooms. The second floor will consist mainly of two large teaching laboratories, and on the third floor will be two lecture rooms, capable of housing 84 and 150 people, respectively, as well as a well-lighted design studio. On each of the four floors there will also be a number of research laboratories. It is estimated that the equipment for the Division will cost about £100,000, part of which is being contributed by private industry. The donations include £5,000 from the Tootal Broadhurst Lee Company, Ltd., of Manchester, and £25,000 from the Man-made Fibres Producers' Committee, acting on behalf of the following producers: British Celanese, Ltd.; British Enka, Ltd.; British Nylon Spinners, Ltd.; Courtaulds, Ltd.; Harbens, Ltd.; Kirklees, Ltd.; Lansil, Ltd.; Lustrafil, Ltd.; Nelsons Silk, Ltd.; and North British Rayon, Ltd.

Very-high-frequency Broadcasting in Great Britain

THE first stage of the scheme by the B.B.C. to introduce sound broadcasting on very high frequencies, as envisaged in the second report of the Television Advisory Committee (see *Nature*, February 13, p. 297), has now received government approval, and work is proceeding in setting up the nine stations that will each send out the home, light and third programmes on frequencies in the range 88–95 Mc./s., using frequency-modulation. The stations will be in Wrotham (Kent), Pontop Pike (near Newcastle), Divis (Northern Ireland), Meldrum (near Aberdeen), Norwich, South Devon, Sutton Coldfield (near Birmingham), West Wales and Holme Moss (near Huddersfield), and will radiate 60 kW., except Wrotham, Norwich, Sutton Coldfield and Holme Moss, which will radiate 120 kW. The network is intended primarily to reinforce, and not supplant, the long-wave and medium-wave services already in existence and should make it possible to receive the three programmes free from interference in many areas where reception on medium wave-lengths is spoiled by interference and fading, especially after dark during the winter months. At Wrotham there are already two transmitters, which have been carrying an experimental service since 1950; a third transmitter will be installed, and the station will be brought into regular service in May next year. The other eight stations will be completed during the following eighteen months; they will be at the same sites as television stations, and the same masts will be used as for the television transmissions. The site for West Wales has not yet been settled. The radio industry in Britain is ready to produce receivers designed for very-high-frequency reception and adaptors for use with existing receivers, and these will become available in the various areas in time for the opening of the respective stations.

Scenes of Red Indian Life in the 1830's

DURING the 1830's, George Catlin, a self-trained artist, painted more than five hundred pictures of Red Indians and Western scenes in the United States, and the majority of these are now lodged in the Smithsonian Institution, Washington, D.C. Through the Information Section of the American Embassy in London, a selection of twenty-seven paintings are being shown in the Whitechapel Art Gallery, London, and this exhibition will continue until August 8 (admission free; daily 11 a.m.–6 p.m.; Sundays, 2–4 p.m.; closed Mondays). In conjunction with the Catlin paintings, there is also the Combined Societies Exhibition of International Photography, 1954. Catlin took great trouble over his work and was well aware of the importance of accuracy, so that his paintings are authoritative records of the life and appearance of Red Indians a hundred and twenty years ago. The paintings at the Whitechapel Art Gallery cover mainly his journeys in the Santa Fe–Fort Gibson area (lying within New Mexico, Texas and Oklahoma) during 1834 and in the Fort Clark–Fort Pierre area (lying within North and South Dakota) during 1832, and depict respectively Mandans and Sioux. Though perhaps the art is not of a first-rate order, the paintings (which are in oil on canvas) are nevertheless very pleasing by the great dignity of the sitters conveyed in the posed portraits, and by the free, lively, almost Impressionist, style of some of the landscapes and broad scenes of village life; the colours are agreeably subdued. It is interesting to note that, after touring the United States in 1838–39, the majority of Catlin's paintings were housed during the 1840's in London at his gallery in 6 Waterloo Place, and his account of his exploits were published in England in a two-volume work entitled "Letters and Notes on the Manners, Customs, and Conditions of the North American Indians" by Geo. Catlin, "Written during Eight Years' Travel amongst the Wildest Tribes of Indians in North America, in 1832, 33, 34, 35, 36, 37, 38, and 39"; a copy of the third edition of this work, dated 1842 and published by Tilt and Bogue, of Fleet Street, London, is on show at Whitechapel and contains four hundred line engravings which Catlin prepared from his original paintings.

Thirty-five Catlin paintings have been acquired by the Chicago Natural History Museum, and these are reproduced in a little book by George I. Quimby, curator at the Museum, entitled "Indians of the Western Frontier: Paintings of George Catlin". Red Indians in various kinds of costumes are depicted, and there is also an interior, a hunting scene and two or three drawings of bison.

Scientia Electrica: New Swiss Journal of Applied Electricity

IN the past thirty years the scientific principles used in electrical engineering have become more complicated and recondite, and the volume of scientific papers has correspondingly grown. In Great Britain the Institution of Electrical Engineers has found a place for all types of papers concerned with electrical science, except for a small number published by the Royal Society, Physical Society, Institute of Physics and elsewhere. The position is not so satisfactory abroad, and a new journal, *Scientia Electrica: Moderne Probleme der theoretischen und angewandten Elektrotechnik* (Band 1, Heft 1, October 1953, pp. 40, 4 Fr.; Heft 2, January 1954, pp. 42, 4 Fr.; Heft 3, June 1954, pp. 46, 4.80 Fr. Zurich: S. Hirzel Verlag), edited by Prof. Max Strutt, has been started in Switzerland to cover current advances and problems in the scientific aspects of the theory and practice of electric technology; the contents of the first three numbers are contributed from colloquia given at the Technical High School, Zurich, by leading experts. It is intended to publish submitted articles of suitable merit within the given terms of reference. The articles so far published contain reviews of recent progress together with some original work of the authors. The subjects chosen are both interesting and important, such as transistor amplifiers, fine transfer in contacts, corona loss in high-voltage transmission, absolute voltage measurement, new insulating materials, and backfires in mercury arc rectifiers. Presumably, submitted articles will often be of narrower scope and confined to original work. If so, those concerned in electrical science will certainly have to take note of this new journal. Even should the articles remain somewhat of a review type, the important work on applied electricity in Switzerland and the standing of the journal's sponsors are such as to ensure the standard and usefulness of its contents.

Staffing of Grammar Schools

In July 1953, a sub-committee of the North-West Division of the Incorporated Association of Headmasters instituted an inquiry into the qualifications, length of service, age distribution and extra remuneration of the teaching staff in the boys' and mixed grammar schools in the area covered by the counties of Lancashire and Cheshire. The inquiry was also concerned with the size of schools, the strength of sixth forms, and at a later stage the academic qualifications and ages of headmasters. The main intention of the survey was to throw light upon the known shortage of teachers in some subjects taught in grammar schools, to view the deployment of specialist and other teachers, and to study the way in which special responsibility allowances which supplement the basic Burnham Salary scales had been awarded. The survey was conducted by W. E. Egner of the Grammar School, Ormskirk, and A. Young of the University of Liverpool. Their report (pp. 20; from the University of Liverpool; 1954; 2*s*.) presents summarized details of the more interesting information elicited by the inquiry, special attention being paid to teachers of science and mathematics; the information analysed has been obtained from sixty-six grammar schools.

National Institute for Research in Dairying, Shinfield: Report for 1953

In the annual report of the National Institute for Research in Dairying of the University of Reading for 1953 (pp. 138 + 1 plate; from the Institute, Shinfield; 1954; 3*s*.) the policy of 1952 has again been adopted of presenting in outline a selection of the advances that have been accomplished during the year under review, particularly some of those with a more practical and obvious interest. This is a very useful measure and serves also to pin-point some of the highlights of research of this team of distinguished scientists. There is still the customary series of extended summaries of researches in progress (or recently completed), and these, together with notes on staff and their publications, constitute a closely packed volume of 138 pages. The director of the Institute, Prof. H. D. Kay, points out that in the selection of advances which have been summarized in brief the choice is of necessity arbitrary and omits reference to much of the work in progress. The product of a collaboration with Sir Charles Dodds and members of his staff at the Courtauld Institute of Biochemistry, London, has been the finding of two *iso*flavones with œstrogenic properties (but far less active, weight for weight, than the naturally occurring œstrogens synthesized by the animal), biochanin A and formononetin, which have been isolated in a pure form from red clover. They have approximately the same œstrogenic activity as the closely related genistein, which is believed to be responsible for much of the œstrogenic activity of subterranean clover. Many of the other advances are of very great interest and importance to the industry, and Prof. Kay and his colleagues are to be congratulated on this outstanding record of achievement.

Enzymic Decarboxylation of γ-Methyleneglutamic Acid by Plant Extracts

The enzymic decarboxylation of γ-methyleneglutamic acid by various plant extracts has been demonstrated by L. Fowden (*J. Exp. Bot.*, 5, 28; 1954). He has shown that γ-methyleneglutamic acid, an acidic amino-acid isolated from groundnut plants, was decarboxylated by enzymes present in extracts of *Capsicum* fruits, barley roots and tulip leaves, and also by intact cells of *Clostridium welchii* S.R. 12. The amino-acid was attacked in a similar manner to, but in all cases at a slower rate than, *l*-glutamic acid. The nature of the enzyme responsible for the decarboxylation of γ-methyleneglutamic acid was further investigated, using preparations from barley roots (which do not contain the amino-acid) and from tulip leaves (in which the amino-acid is normally present, together with larger amounts of its amide form, γ-methyleneglutamine). The effects of *p*H, inhibitors and partial heat denaturation upon the enzyme systems present in the barley and tulip extracts indicated that a single enzyme was responsible for the decarboxylation of both *l*-glutamic acid and γ-methyleneglutamic acid. Although the *Cl. welchii* rapidly deamidated and then decarboxylated *l*-glutamine, γ-methyleneglutamine was not attacked by the organism.

Bowen Prizes for Papers on Scientific Instrumentation

The Institute of Physics has awarded Bowen Prizes of fifteen guineas to the following for papers published in the *Journal of Scientific Instruments* during 1953: A. G. Milnes and T. V. Vernon (jointly), Royal Aircraft Establishment, Farnborough (saturable-core reference source for use with magnetic amplifiers); G. D. Dew, National Physical Laboratory, Teddington (preparation of plane diffraction grating replicas for helical rulings); and G. D. Archard, Research Laboratory, Associated Electrical Industries, Ltd., Aldermaston (magnetic electron lens aberrations due to mechanical defects). The Prizes are awarded to persons less than thirty-five years of age for papers of originality, scientific value and practical utility to instrument makers and users. The money is provided by the Scientific Instrument Manufacturers' Association of Great Britain, Ltd., from the Bowen Trust Fund established by the late Mr. William Bowen.

University Teachers: Conference in Vienna

The eighth Conference of University Teachers, organized by the International Association of University Professors and Lecturers, will be held in Vienna during September 9–14 at the University of Vienna and at the Vienna Hochschule für Welthandel, under the chairmanship of Prof. Francesco Vito, of Italy. The Conference will be open to all members of the Association and of its affiliated national associations of university teachers, to university administrative staff, and to others directly interested in matters of university education; university institutions in which there are, as yet, no sections of the Association are invited to send representatives of their teaching staff. The topics to be considered include the following: relations between scientific research in the universities and in industry; selection of students for university entrance (in particular, the systems and the extent of their assistance from public funds, bursaries, scholarships, etc.); conditions of employment of university teachers abroad, and the contractual obligations involved; main obstacles to the international exchange of university teachers; and methods of international co-operation in the university and scientific spheres. A registration fee of £1 will be charged. Further details can be obtained from the Secretary, IAUPL, 19 Dunraven Street, London, W.1.

Utilization of Fish and Agricultural Food Products

A CONFERENCE on new developments in the utilization as food of fish and agricultural products will be held in Aberdeen during September 30–October 2, under the auspices of the Society of Chemical Industry (Aberdeen Section and the Food and Agriculture Groups) and the Institute of Biology (Scottish Branch). The conference will be opened by Dr. F. N. Woodward, director of the Institute of Seaweed Research, and Dr. Norman Wright, scientific adviser to the Minister of Food, will give the closing address. Topics to be discussed are: the feeding values of oats, straw and oat-milling products; the vacuum dehydration of foodstuffs; freezing at sea; quality of sea-frozen cod; recent developments in fish by-products; supplements in the rations of livestock; distillery by-products, and their recovery and use as animal feeds; seaweeds and their constituents as foodstuffs; large-scale culture of microscopic algæ as food. There will be visits to the Ministry of Food Experimental Factory, the Torry Research Station and the Rowett Research Institute. A detailed programme and registration form will be available early in August from the Honorary Secretary (F. T. Walker), Institute of Biology, Scottish Branch, 25 Inverleith Gardens, Edinburgh 4.

University of London

THE title of professor emeritus in the University of London has been conferred upon the following on retiring from their respective chairs: Prof. H. V. A. Briscoe, inorganic chemistry at the Imperial College of Science and Technology; Prof. H. Munro Fox, zoology at Bedford College; Prof. Morris Ginsberg, sociology at the London School of Economics and Political Science; and Prof. Hyman Levy, mathematics at the Imperial College of Science and Technology. The following have been appointed to University readerships, tenable at the institutions indicated: Mr. D. G. MacRae, sociology at the London School of Economics and Political Science; Dr. R. G. White, bacteriology at the London Hospital Medical College; and Dr. J. H. Wilkinson, chemical pathology at Westminster Medical School.

The Colonial Service: Recent Appointments

THE following appointments have recently been made in the Colonial Service: L. W. Harwood and N. Lamont (agricultural officers, Fiji), senior agricultural officers, Fiji; R. J. M. Swynnerton (assistant director of agriculture (field services), Kenya), deputy director of agriculture, Kenya; R. P. St. John Watkin (chemist, Tanganyika), assistant government chemist, Nigeria; G. S. Brown (senior assistant conservator of forests, North Borneo), senior assistant conservator of forests, Federation of Malaya; W. B. Tevendale (geologist, Geological Survey Department, Gold Coast), senior geologist, Geological Survey Department, Gold Coast; D. A. R. Campbell, V. T. Domville and B. F. Topper (agricultural officers, Jamaica), senior agricultural officers, Jamaica; A. S. Martin (medical officer, Jamaica), assistant bacteriologist, Jamaica; R. Foster, scientific officer, Tanganyika; R. N. Gourlay, veterinary officer, Uganda; J. M. Ross, veterinary officer, Northern Rhodesia; R. N. Chrystal, forest entomologist, Cyprus; C. D. Cooke, veterinary officer, Nigeria; J. V. Thirgood, sylviculturist, Forestry Department, Cyprus.

The Night Sky in August

FULL moon occurs on August 14d. 11h. 03m., U.T., and new moon on August 28d. 10h. 21m. The following conjunctions with the moon take place: Aug. 2d. 18h., Venus 6° N.; Aug. 6d. 03h., Saturn 8° N.; Aug. 10d. 08h., Mars 3° S.; Aug. 25d. 01h., Jupiter 1° N. In addition to these conjunctions with the moon, Mercury is in conjunction with Pollux on Aug. 3d. 23h., Mercury 7° S., and also in conjunction with Uranus on Aug. 4d. 12h., being 0·6° S. of Uranus. On Aug. 31d. 01h., Venus is in conjunction with Spica and is 0·1° N. of the star. During the first part of the month Mercury is visible as a morning star, rising at 2h. 50m. and 4h. on August 1 and 15, respectively, and is in superior conjunction on August 21. Venus, an evening star, sets at 21h. 10m., 20h. 35m. and 19h. 50m. at the beginning, middle and end of the month, respectively; the visible portion of the illuminated disk varies from 0·655 to 0·523, and the stellar magnitude from −3·6 to −3·9. Mars sets very soon after midnight on August 1, and at 23h. 25m. and 22h. 45m. on August 15 and 31, respectively; but as its declination is about 28° S., it is not very favourably placed for observation in the British Isles. Jupiter is a morning star, rising at 2h. 25m., 1h. 45m. and 1h. on August 1, 15 and 31, respectively. It is easily identified (stellar magnitude −1·5), and its motion from west to east of δ Geminorum during the month is obvious. Saturn, an evening star, sets at 22h. 35m., 21h. 40m. and 20h. 40m. at the beginning, middle and end of the month, respectively, stellar magnitude 0·9. Its slow easterly motion from κ Virginis is easily detected. The Perseid meteors attain a maximum about August 10–12, but bright moonlight will interfere with their observation. No occultations of stars brighter than magnitude 6 occur during August.

Announcements

THE University of Leeds has conferred the title of reader in physics on Dr. F. E. Hoare, senior lecturer in the Department of Physics; Mr. E. W. Bennett has been appointed lecturer in the Department of Civil Engineering of the University.

THE University of Cape Town is offering a scholarship of £200 a year tenable for three (or possibly four) years to a student from Great Britain proposing to take a degree course at the University, beginning in March 1955. Applications should be forwarded not later than August 15 to the Secretary of the Association of Universities of the British Commonwealth, 5 Gordon Square, London, W.C.1.

THE Research Fund of the Chemical Society provides grants for the assistance of research in all branches of chemistry. About £700 a year is available for this purpose, the income being derived from a donation of the Worshipful Company of Goldsmiths, from the Perkin Memorial Fund, and from other sources. Applications for grants should be submitted to the General Secretary, Chemical Society, Burlington House, Piccadilly, London, W.1, on the appropriate form not later than November 5.

THE third conference of the British Occupational Hygiene Society will be held at the London School of Hygiene and Tropical Medicine on November 1; it will be devoted to a discussion of radiation hazards in industry. Application forms for the conference can be obtained from the Hon. Secretary of the Society, Mr. P. C. G. Isaac, Public Health Engineering Laboratory, King's College, Newcastle upon Tyne.

TECHNICAL COLLEGES AND INDUSTRY IN BRITAIN

THE papers presented at the Conference on Technical Colleges and Industry arranged by the Education Committee of the Federation of British Industries at Ashorne Hill on May 5–7 covered a wide field. They attempted to formulate industry's ideas as to what it expects of the technical colleges in Britain, and, on the part of the technical colleges, to present the perspective in which the colleges work and their relations to the universities and the schools as well as to industry itself. Such discussions flowed naturally on to the broadening of the technical college and its place and function in training for management.

So far as the Conference leaves any dominant impression, it is one of the complexity of the whole problem of technical education in Britain, and the futility of any attempt to improve its standard or expand the provision for technical education without taking full account of the educational system of the country as a whole from university-level downwards, and in co-operation with industry. The inadequacy of such piecemeal tactics as the Ministry of Education has hitherto followed was clearly displayed, by implication rather than by explicit condemnation. There was no attempt to formulate a definite policy at the Conference; but essential features of any effective policy were indicated, though at the same time the need for flexibility and variety was equally stressed. It was certainly made clear that many sections of industry are already fully prepared to co-operate and that there should be a generous and prompt response to a clear and bold lead.

Sir Arthur Smout (Murex, Ltd., and Murex Welding Processes, Ltd.), in some outspoken comments on the present position, urged afresh the establishment of a Technical College Grants Committee on a par with the University Grants Committee, which would enable the administration and finance of at least the major technical colleges to be taken out of local and party politics. He insisted, too, that we cannot expect to have an educational system worthy of a great nation on the cheap, and while it was evident that industry as represented at the Conference is likely to support generously a policy of expansion for technical education, such support presupposes a policy and a recognition by the Government that technical education is a sound investment. Moreover, while it seemed to be generally admitted that only a relatively few technical colleges could be expanded into major institutions under such a policy, the importance of the contribution to be made to technical education by the rest was equally recognized. Dr. P. F. R. Venables (principal, Royal Technical College, Salford) suggested that the term 'higher technological education' should be restricted to postgraduate education; and this suggestion might well help not only to remove confusion but also to eliminate the difficulty, real or imaginary, which is sometimes caused by status. Dr. Willis Jackson, indeed, expressed the opinion that the weakness of Great Britain relative to the United States is at the level of technique and not at the professional level, and that post-war discussions here have concentrated too much on the professional grade rather than on the technician.

Much that was said at the Conference served to clarify these interrelationships. Sir Arthur Smout, for example, pointed out that we must get away from the idea that all higher education must be of the university type, and he visualized the technical colleges as the appropriate means for training for industry young men who are ill-suited and ill-equipped for university life. Further, he believes that a main purpose of the 'sandwich system' is to encourage a good type of recruit to join smaller firms direct from a grammar or secondary school and obtain the appropriate technical training in a technical college while based on the works. Apart from thus integrating practical training in the factory with technological studies in the college, Sir Arthur sees great advantages in bringing the smaller firms into relationship with technical colleges in this way.

The importance of maintaining a variety of channels for technological training was emphasized by other speakers. Dr. Venables pointed out that the fulcrum of the definition of technology is in the scientific study, while with a craft it is in the exercise of a skill or technique. Fundamentally, a technology requires the student to undergo an exacting scientific discipline which confers mastery of the theoretical concepts required for widely differing ends. In his view the difference between technological education in the universities and in the technical colleges is simply one of the timing or phasing of the two main elements—the science and the art of the technology. In the universities, the phasing is preponderantly scientific, with the art phase introduced mainly as a pre-undergraduate year, as brief intermittent phases of vocational experience in industry, and a thorough postgraduate phase; but for most technical college students the phases are more interpenetrating or even concurrent or alternate as in 'sandwich courses'. While he believes there is an ample reserve of ability in Britain for training in technical colleges, it is on condition that such expansion of the technical colleges does not contemplate the raising of more than the minority of such colleges to provide largely technological, as distinct from technician or craft, education. We should preserve flexibility and also encourage transfer between courses and occupations, so that the best ability when found can be moved forward and upward.

Dr. Venables suggested that the main elements in our policy should be the development of 'sandwich courses' on a recognized national basis, a national standard of intake and a national length of courses. This would remove much of the present confusion and though he believes it is also desirable that more research should be carried out in the technical colleges, that depends on the recruitment of the appropriate staff and the establishment of conditions of service which will attract competent men. Dr. Willis Jackson (Metropolitan-Vickers Electrical Co., Ltd.) supported Dr. Venables in his general view as to the relative functions of the universities and the technical colleges; the latter, he suggested, should provide courses which are more technical and more related to industrial practice. Some university courses are already technical enough, and he would like to see the universities rather ensure a sounder foundation in pure science. Moreover, in view of the increasing interrelation of different branches of technology and their increasing mutual dependence on pure science, he believes they should be drawn together at a comparable level and in intimate association with pure science departments of high standing.

Dr. Jackson did not minimize the difficulty of any such attempt; but he also urged that the technical colleges rather than the universities should encourage the development of short-term specialist courses, whether full-time or evening, and the universities should concern themselves only with the scientific and analytical foundations of prospective technological development—with what industrial practice should be five or more years ahead rather than with what it is to-day. The technical colleges, moreover, can only make their full contribution in the teaching of current industrial practice if industry is willing to co-operate to the extent of making available the services of the appropriate senior members of its staff.

In opening the discussion on the broadening of technical education, Sir Reginald Vernon Smith (Bristol Aeroplane Co., Ltd.) pointed out that the responsibility once again rests with the schools and industry as well as with the technical colleges. So far as industry is concerned, the standard of selection adopted by industry for its recruits is an important factor, as is the pattern of training afterwards given. Technical education, moreover, is a continuing process and much can be done by the intelligent and liberal use of postgraduate courses, residential courses, interchange schemes, overseas travel fellowships and the like. On the part of the technical colleges, he suggested, like Dr. Venables, that emphasis should be placed more on the fundamentals or intellectual discipline of a technology than on the applications, and that technical subjects should be presented against a stimulating background of historical development and in relation to allied subjects. The latter suggestion found confirmation in Prof. Rex Knight's observations on the probable reaction of technical college students to the widening of their programme of studies. Prof. Knight (professor of psychology, University of Aberdeen) believes that any new subjects must be linked to subjects of which the vocational significance is clear; they must be seen by the student to be an integral part of the preparation for the job he is to do in industry. They must also, he thought, form part of the target the student has to hit, though not necessarily as subjects of examination. Prof. Knight also remarked that much of the widening of curriculum would have to be done in industry, and while he believes that in the technical colleges, even more than in the universities, there is great need for grading students according to their ability and educational achievements, to facilitate both the prosecution of their individual studies and the removal of specific defects in their educational equipment, he stressed finally that all such further education is dependent on effective co-operation between all concerned. He also endorsed Dr. Venables's remark as to the importance of social facilities, and the suggestion that the Federation of British Industries might press for greater proportionate facilities for technical college students.

Mr. H. A. Warren (principal, South-East London Technical College), who followed Sir Reginald Verdon Smith, from the point of view of the technical colleges went rather deeper into the implications of the broadening of technical education. It should be remembered, he pointed out, that this age is extremely preoccupied with technics, and we have above all to present technics or technology as a means to an end in terms of human values, not as an end in itself. If we fail to put power into the hands of the coming generation with a sense of purpose and of responsibility, we are in danger of being overwhelmed by an environment of our own making. Technical education, moreover, is wholly secular, and more regard should be paid to those fundamentals of the human spirit which limit and constrain technical education. With much of what Prof. Knight said he agreed; but he emphasized that the decisive factor is the outlook and capacity of the teacher, and here, he said, the Federation of British Industries can be of great assistance. The Federation can also make it widely known that industry desires and values this broadening of technical education.

Dealing specifically with management studies in the technical colleges, Mr. Bertram White (formerly technical director of the Federation of British Industries) said that the technical colleges have here a valuable but limited contribution to make. He too stressed the importance of the quality of the teaching and suggested that the Urwick Committee was over-optimistic in its estimate of the potential supply of men and women with appropriate experience willing to devote part of their time to the teaching of management. He believes that lectures on management are often delivered by teachers with no practical industrial experience; indeed, generally the business community lacks the faculty of coherent and articulated expression of its ideas. While much closer association with the professional associations is required, any further development of management studies should proceed by way of agreement. Much closer association between the technical colleges and local industry is required, particularly in teaching the various techniques through which management achieves its purposes. Besides this, technical colleges in their management studies should endeavour to teach background subjects: those aspects which are usually termed 'general management' subjects are best learned on the job under good supervision. Industry must train its own managers; the role of the technical colleges is supplementary. He advocated the abandonment of courses that are ineffective and cannot be improved and also, for the next decade, disregard of certificates and diplomas in management studies. The Federation of British Industries and the British Institute of Management should confer with the associations of technical institutes to ascertain those areas of the country in which more co-operation between industry and the technical colleges and greater awareness of the value of management training are required.

Mr. J. Wilson (principal, Birmingham College of Technology), who followed, agreed that most of the difficulties in education for management arise from over-enthusiasm and pressure for development started up by the Urwick Report. There has been some lack of consultation with industry; but the staffing position is the critical factor and limits the rate of progress. He also agreed that it is desirable to concentrate highly qualified staff in a few centres providing facilities for all levels of interest in industrial administration. The urgent need in the training of men for management is to bring into partnership all those bodies already concerned with it separately, from universities to trade unions, from technical colleges to professional associations, and from public to private enterprises.

CANADA'S TO-MORROW

THE Canadian Westinghouse Co., Ltd., believes that "business and industry can flourish only as the whole nation advances in the direction of the good life", and a few months ago expressed its appreciation of fifty years spent in Canada in a rather unusual way—by the sponsoring of a conference at Quebec for the study of the country's future. The papers read at the conference provided an excellent picture of Canada's past and present, and also gave some glimpse of the future. "A sober, calm, highly critical assessment" was the description of one of the guests, who remarked on the lack of that complacency which might so easily have resulted from the sudden up-surge in the country's fortunes. Canadians of the calibre of the eight conference speakers clearly have a very realistic grasp both of Canada's internal situation and of the part that her people must play in the troubled world of to-day.

Canada's resources are both human and natural. B. K. Sandwell discussed the people, whose numbers, he is convinced, could be greatly increased without adversely affecting the present high standard of living, so great are the country's resources and so vast the potential market for primary and secondary products, both within Canada and in the United States and elsewhere. The natural resources were discussed in a comprehensive stocktaking by Maxwell W. Mackenzie. He stressed in particular the suitability of the timber of the Canadian Shield for newsprint, the value of the mineral resources of the Shield and other areas, and the significance of the fact that hydro-electricity can easily be transmitted to the points where energy is required. He believes that the time has come for electricity, gas and oil to be distributed through a national network, since their part in Canada's future must be at least as great as has been the contribution of rail, road and water transport in the past. He also emphasized the importance of conservation practices and research programmes, especially for timber and cereals, which together accounted for 45 per cent of the value of Canada's exports in 1951. Food production, apart from wheat, should, he suggested, be based on probable domestic demand. The United States and other countries should still be permitted to purchase primary products such as timber, though at the same time Canada must press for the reduction of trade barriers, especially those which prevent the export of processed products such as plywood and composition boards. She must also be courageous in her attitude towards, and exploitation of, her extensive resources. He sees no justification for the hoarding of the nation's very considerable wealth of copper, lead, zinc, nickel, cobalt, tungsten, iron ore, titanium and other lesser known but important alloy metals, or for placing restrictions upon the export of primary products. The mining of the iron ore of Labrador and of lead and zinc at Pine Point on Great Slave Lake, for example, would undoubtedly result in the opening-up of vast new stretches of country.

These great resources, while providing Canadians with considerable material comfort and higher standards of living, also help to give rise to what R. K. Stratford, scientific adviser of Imperial Oil, Ltd., called "the greatest social challenge in history". Several of the papers dealt with the impact of economic development upon the social and political life of the community, through education, industry and government. It was recognized that "we refuse to give to our hearts and minds the thought and care that we lavish on our physical needs", and that far more attention is commonly directed to the problems of industry and resources than to the study of urban and rural social problems. One speaker pleaded for the expansion of university departments, whence might come "long, systematic studies of the human being under different environmental conditions". Another deplored the gap between the two main cultures, the French and the English, and advocated the erection of bridges across the cultural gulf: this, she believed, might be achieved by an increasing sense of the need, "not for a superficial and chatty bilingualism, but for a genuine mastery of the two languages". Realistic recognition was also given to the third great cultural force, that of Canada's neighbour, the United States. Faced with these various influences and traditions, there should be encouraged in Canadian schools "individual self-reliance in opinion, critical dissidence, intelligent non-conformity, the ability at least occasionally to stand aside and stand up for one's own individual beliefs".

The role of government, in economic and social affairs, has changed considerably during recent years. Government encouragement of economic activity, as in the building of communications and the fostering of settlement, has given way to private enterprise, and public authorities are now increasingly concerned with social security and short-term economic stability. Prof. Maurice Lamontagne, of Laval University, claimed that the Canada of the future needs neither capitalism nor socialism but a complementary relationship between private initiative and government action, with the Federal Government playing a dominant part in the collective effort to maintain economic equilibrium.

Prof. D. G. Creighton, professor of history in the University of Toronto, turned the thoughts of the conference to Canada's place in the world. The country has already established her independence within North America and a prominent place in the Commonwealth, and is rapidly securing for herself an acknowledged position in international affairs. She has, in his view, to accept a world in which Communism dominates the larger part of Asia, and must be prepared to abandon what he called "our complacent, parochial North Americanism". It is essential that Canada should give to the United Nations its steady support.

At the close of the conference Prof. D. W. Brogan, as "an outsider looking in", surveyed the wide range of papers and subjects discussed. He said he was impressed by the wealth of Canada's resources, but he saw "the basic source of Canadian prosperity in the character of the Canadians and of their civilization". Canada has shown the world that the highest potentialities of modern technology are attainable without violence, disorder, or cultural savagery. As population increases—as it should—by natural increase and by immigration, the specifically Canadian aspects of North American culture must be fostered and the double culture of Canada steadily fused. Each group must express its own vision of Canadian life, at the same time sharing that vision with its neighbour. Canada, Prof. Brogan reminded his listeners, "is the heir of the two great formative traditions of western Europe: it is her pride and opportunity to develop both".

Canada's to-morrow is bright and promising because Canadians are proud of her past and conscious of the opportunities of the present. Through the public spirit of a great concern—typical of many of the corporations of North America—and because of its confidence in the nation's future, more than three hundred representatives of Canada's commercial, industrial and cultural life were able to share in the thoughts and concerns of a few of their fellow-countrymen through this conference.

The papers form an invaluable commentary on Canadian thinking to-day, and on Canada's prospects to-morrow. Fortunately, the Canadian Westinghouse Co. has now published the papers in book form*, thus making available for a much wider audience the deliberations of this very balanced and comprehensive conference.

ROBERT W. STEEL

THE SPORTS TURF RESEARCH INSTITUTE

SILVER JUBILEE

TO mark the silver jubilee of the Sports Turf Research Institute, a conference and open day were held at its headquarters, St. Ives Research Station, Bingley, Yorkshire, on July 1. A most satisfactory attendance, including representatives from sports clubs, sports associations, education authorities and municipalities throughout the British Isles, was presented with a very full day's programme in which major items were experiment plot demonstrations, educational exhibits, displays of modern machinery and the presentation of various papers on turf topics at intervals during the day.

The director of the Institute, Mr. R. B. Dawson, spoke about the developments of scientific turf management during the past twenty-five years, stressing particularly the big improvements in design and range of equipment that have taken place. He referred also to the growth of the experimental and other work of the Research Station. Mr. J. R. Escritt (soil chemist) discussed the relative importance of physical and chemical properties of soils for turf production, and Mr. J. Drew Smith (plant pathologist) dealt with turf diseases and his own work on fungicides. The fourth paper, given by Mr. G. Wright, a member of the Board of Management, described turf research work in progress at several research centres in the United States, emphasizing the big problems created in some parts by climatic factors adverse to good turf production.

The Institute (formerly known as the Board of Greenkeeping Research) has the stated aim of raising the general standard of sports turf. It is supported by subscriptions from numerous interested bodies, including sports clubs, golf clubs, industrial welfare clubs, sports associations, public authorities and education committees. Management of the Institute is in the hands of a Board of Management which includes representatives of the main sports controlling bodies, namely, the English Golf Union, Scottish Golf Union, Golfing Union of Ireland, Welsh Golfing Union, Football Association, Football League, Ltd., Lawn Tennis Association, Rugby Football Union, Rugby Football League and the English Bowling Association. The Board has available both scientific and practical advisory committees for consultation. In pursuance of its object, the Institute has a comprehensive research programme for investigating problems of general turf management, problems of individual management of turf for particular purposes and, of course, the control of weeds, pests and diseases. Extensive field trials running to many hundreds of plots are backed by useful laboratory facilities.

Field work at present in progress at the Research Station (and demonstrated on the open day) includes trials on height of cut, top-dressing materials, long-term fertilizer treatment, weed control, disease control, grass growth stunting and seeds mixtures. Although the main experimental ground bears a considerable number of trials, many experiments can only be carried out satisfactorily at outside centres; for example, at present a new series of simple trials on seeds mixtures for renovating football grounds is in progress. Turf diseases and their control are receiving particular attention at the moment, with attempts to produce cheaper and more efficient materials for controlling known turf diseases. It is interesting to note that this concentration on disease problems has revealed that one or two new diseases previously unrecognized occur quite frequently, and work is proceeding on methods of control.

Knowledge gained from the various trials is passed on through the advisory work of the Institute, through instructional courses for groundsmen, greenkeepers and other interested persons and also through lectures given by members of the staff at various centres throughout Great Britain. In addition, an annual *Journal* is produced and also brief quarterly *Bulletins*, both these publications being circulated to all affiliated members. The advisory services are being increasingly called upon, and more and more is being demanded of the staff concerned in this work.

The Institute was founded in 1929 by the golf clubs through the four national Unions; but the great expansion of activities, particularly since the Second World War, in various other directions, led to a reorganization and the formation of the Sports Turf Research Institute. The status of the organization as an independent non-profit-making scientific body was recognized by the granting of a licence from the Board of Trade in August 1951, thus permitting the Institute to be registered and to operate without the use of the word 'Limited' in its title. The former Board of Greenkeeping Research ceased to exist on September 3, 1951. It has become increasingly obvious that the Institute has an important part to play in the future as in the past. More and more its advice is called upon in the construction of new playing fields for all kinds of bodies. In particular, the educational programme of producing more new school playing fields demands a great deal of attention from the Research Station in order to enable the education authorities to produce fields of sufficient quality without unnecessary expenditure of public funds.

DEVELOPMENT AND UTILIZATION OF WATER RESOURCES

THE eighteenth session of the United Nations Economic and Social Council, which opened in Geneva on June 29, discussed among other items a report on the Development and Utilization of Water Resources*. This report was prepared as a result of earlier resolutions calling for information on the work being done by the specialized agencies and

* United Nations: Economic and Social Council. Report on the Development and Utilization of Water Resources. Pp. 20. (London United Nations—London Information Centre, 1954.)

other international organizations engaged in the broad field of water control and utilization.

The complex nature of the inter-relationship between the various factors which have an influence upon, or are in turn affected by, the availability of water is first stressed—the needs of agriculture, inland navigation, industrial and domestic demands, electric power and the like are considered in relation to techniques of conservation to prevent excessive run-off, soil erosion and flood damage. The report then directs particular attention to three aspects: the first need in any activities on water control is the organization of a continuous collection of hydrological data which must be available for a considerable stretch of years to be of any value; in this connexion the suspension of the United Kingdom Inland Water Survey (referred to in *Nature* of November 7, 1953, p. 823) is again seen to be a retrograde step.

Secondly, attention is directed to the topic of watershed management, as this is regarded as an important but neglected aspect of water conservation. It is claimed that effective control in these initial stages reduces the need for river-training works and downstream flow-control measures. It is suggested that there is a regrettable lack of understanding of watershed management, not only on the part of the general public but also among those who are responsible for the political and economic decisions which are often made on water supply. The need exists to build up a body of information on this subject and also to arrange for its dissemination, perhaps through Unesco. The third aspect selected for special attention is the use of water for industrial purposes. This is considered to be the largest single factor making for the increased demand for water which is being experienced in most countries of the world to-day. Some dramatic illustrations of the growth of this demand are given: in 1950 the industrial use of water in the United States was higher than the agricultural use, and the Paley Commission estimates that by 1975 industries will use two-thirds of all sweet water and that availability of water will be the main determining factor for industrial location. To produce a ton of steel now requires 65,000 gallons of water, and to refine a barrel of crude oil requires 18½ barrels of water; a ton of sulphate paper needs 64,000 gallons, while almost astronomical figures are required for thermal generating stations and atomic power stations.

To meet these and related problems of water pollution, the report considers the possibility of a more effective integration and co-ordination at various levels of the interested agencies and organizations. A strong case is made for the creation at national level in each country of a 'water board' representing all the interested government departments and local government bodies concerned with any of the numerous aspects of water conservation and utilization. This is a recommendation that might well receive careful consideration in the United Kingdom, although we are not alone in this lack of one central body: few countries have so far succeeded in co-ordinating their local activities on water development. Until this has been done, however, there seems little hope of efficient and successful co-ordination and co-operation at the regional and international level. Meanwhile, it is recommended that the United Nations Organization should encourage the holding of technical conferences and meetings of existing hydrological agencies. The United Nations Organization should also serve as a clearing house on water matters and perform such other functions as it may appropriately undertake in implementation of the Economic and Social Council's resolution on water control (Resolution 417, XIV).

W. G. V. BALCHIN

NETWORK ANALYSER OF THE ELECTRICAL RESEARCH ASSOCIATION

THE alternating current network analyser has now become established as an essential tool for the design, operation and study of electrical power systems. The direct representation of the electrical characteristics of the network components by variable calibrated elements with suitable sources of alternating current, flexible means of interconnexion and sensitive measuring equipment readily applied to any point on the network makes possible examination of a complicated network for power flow, transmission efficiency, stability and fault conditions with an ease and accuracy quite beyond the range of human computation, while permitting an experimental approach as yet impracticable with a digital computer. The same equipment can in principle be used in the study of any systems capable of representation by linear differential equations and certain non-linear problems within a range dependent on the versatility of the components and measuring equipment.

The network analyser constructed by the Electrical Research Association, the first completed section of which was exhibited to the technical and scientific press on April 28, has been designed for application to the widest possible range of problems. To this end the equipment can operate at any frequency from 160 c./s. to 16 kc./s., so that frequency can be a variable or one of the unknowns in a problem. The maximum accuracy is at the 'base' frequency of 1,592 c./s. ($\omega = 10^4$). This versatility is accompanied by the possibility of extension to a size not less than that of any existing analyser. The equipment is believed to be unique in providing steady-state, transient and harmonic solutions on the same installation.

The impedance elements, mounted in racks, are connected by twin cables to terminals on a 'plug board' and thence by pairs of flexible cords to plugs which can be inserted into sockets in an interconnecting board to form the nodes of a network. The potential drop across a 20 milliohm shunt in series with one of the flexible cords associated with each element, and the potential difference between any two nodes of the network may be connected by a selection system to the terminals of the central measuring equipment which indicates simultaneously current, voltage, load and reactive load at the selected points. Two independent selection systems, which can be cross-connected, make this measuring equipment extremely versatile. Monitoring and fault-finding indications are provided.

Physically small components used in the network elements yield an inexpensive and compact design with short interconnecting leads and thus increased frequency-range. Small components require a low power-level, to avoid thermal effects in resistors and non-linearity in inductors. The level adopted is 2·5 mW., 500 mV. and 5 mA. for the base (that is, 100 per cent) values, with a range up to 400 per cent n voltage and current. This means that only 100 μV. s available across a shunt for the measurement of current at 100 per cent level. At the same time a resolution and repeatability of 0·1 per cent of amplitude (and 0·1° of phase angle at amplitude levels greater than 10 per cent) has been aimed at, with an absolute accuracy of 1 per cent and 1° at the base frequency. Such stringent requirements call for a bridge method of measurement.

For voltage measurement a voltage derived from the network is compared in a transformer with an nternal reference signal. The latter is derived from a hree-phase master oscillator through a magslip phase hifter and a potentiometer amplitude adjustor. The same oscillator energizes the network through phase shifters and potentiometers in active units representing generators. The difference of the two signals is derived from the transformer and provides the input to a servo-system which adjusts the shafts of the eference phase shifter and potentiometer until the reference signal becomes equal in phase and magnitude to the unknown voltage and the error signal disappears. The phase and magnitude of the network voltage (referred to a phase of the master oscillator) are then indicated on dials ganged with the shafts of he reference phase shifter and potentiometer. The current bridge is identical except for a difference in the operating level.

The shafts of both bridges drive the elements of a small analogue computer, also servo-operated, which indicates the products $P = VI \cos \varphi$ and $Q = VI \sin \varphi$. Here φ is the direct phase angle between the voltage V and current I measured, and hence P and Q represent the active and reactive volt-amperes.

Although the equipment is for use primarily in the service of the electrical industry, it is intended that so ar as possible its versatility and flexibility shall be made available for the solution of problems within its range irrespective of their origin.

FAMILY PLANNING

IN an article on family planning*, Dr. Philip M. Bloom discusses the principles of family spacing which have been commonly accepted by most civilized communities. Besides accounts of the 'safe' period and the more usual methods of contraception like the condom and cervical cap, Bloom discusses investigations now being made into the development of oral contraceptives. At present, research is along four lines. In the first place an anti-fertility substance, phosphorylated hesperidin, is being investigated. It is thought that the sperm liberates an enzyme, hyaluronidase, which acts on the capsule of the newly-discharged ovum in such a way as to allow penetration and fertilization by the sperm. Phosphorylated hesperidin is a non-toxic inhibitor of hyaluronidase; an American worker has administered it orally to three hundred couples in an attempt to control fertility. He claims much success but corroboration is needed.

Secondly, an anti-fertility factor of an entirely different nature is that contained in the plant, *Lithospermum ruderale*. It is likely that it either inhibits the secretion of the pituitary gonadotrophic hormone or neutralizes it. Dried extracts of *Lithospermum* used on laboratory animals of both sexes have reduced fertility; nothing is really known of its effects on human beings. In England, a gromwell (*Lithospermum officinale*) has been found to contain this anti-fertility factor, and properly prepared extracts are non-toxic. They permit the possibility of trials in human volunteers. A third line of research is that of finding substances such as anti-vitamins or anti-hormones which will prevent development of the ovum or curtail its ability to embed itself in the endometrial lining of the uterus. Fourthly, there is the possibility of active immunization. An antigen which would produce immune bodies in the female capable of preventing either fertilization or nidation offers interesting speculation. Langer in New York has used such an antigen in female mice. With extracts of human umbilical cord given in three weekly injections, he found that female mice brought into contact with fertile males following a wait of three weeks showed delays in producing young in about 80 per cent of cases. Further, some of these substances may act as early abortifacients and would not be readily accepted by large sections of society. Others, by interfering with ovulation, would produce irregularities in menstrual cycles which may cause considerable emotional upsets in women. A great deal of further research work has to be done before an easy oral contraceptive is discovered and accepted; but it is probable that at some future time such a substance will be found.

SALMON MIGRATION AND THE ENVIRONMENT

By Prof. A. G. HUNTSMAN

Fisheries Research Board of Canada and University of Toronto

WHAT fish do of themselves is simple enough; but where they go is greatly complicated by environment and weather. This is a general conclusion from twenty years investigation of salmon and other fishes with the view of their management. Where they go is basically important in management and needs to be predicted.

Where salmon go may, as is most natural for us, be considered psychologically in the belief that they go where they will, and they are free to go anywhere in the water. Or it may be considered physiologically in the belief that their internal processes determine where they go, and physiology has now the highest repute among zoologists. But, to follow either of these courses is to reckon without one's host. The host in this case is the environment. Claude Bernard concluded that living is the continuous adjustment of internal conditions to external: "Ce n'est point par une lutte contre les conditions cosmiques que l'organisme se developpe et se maintient; c'est, tout au contraire, par une adaptation, un accord avec celles-ci"[1]. This means that the environment sets the pace, that it determines living.

If we can rid ourselves of preconceived ideas, there is no mystery in salmon migration. It is easy to see that the anadromous salmon is carried downstream and swims back up, and that the katadromous eel swims upstream and is carried back down. It is also easy to see that fish are carried downstream when they wander and do not resist the current sufficiently by heading and swimming upstream, and also that, when wandering vigorously, they head and swim upstream under the stimulus of being carried over the bottom by a current. Closeness of their relations with the bottom, which provides the stimulus, determines whether they go upstream or downstream. That the fish may keep down from too much light near the surface of the water, and up from close contact with the bottom, means variety in the stimulus for ascent. Heading upcurrent, avoidance of strong light and avoidance of solid or hard boundaries can be observed generally in animals that move about in water or in air, and these behaviours may be considered as simple and basic, no matter how complicated may be their psychology or their physiology.

The following account briefly summarizes what has just been worked out for our best example of fish migration. The details will be given in a bulletin on fish and fishery management that is in preparation for the Fisheries Research Board of Canada.

The Margaree River of Cape Breton Island happens to have particularly good conditions for developing a rather complete picture of the migration of the local salmon, even for the sea portion when they are for the most part deep in the water and out of sight. When small salmon or parr that live for several years in the river are swept into the sea by heavy floods, they reach the Margaree estuary. They survive where the water is not so salt as to kill parr. Thereupon they ascend small streams tributary to the estuary[3]. When adult Margaree salmon are tagged after spawning and are liberated in the estuary in the autumn, they may or may not (depending upon floods) ascend the river and be found in it as late as the middle of the next summer. Finally, they are found only in the sea, and, until they have again become fat and vigorous, only along the outflow of the river for ten or twenty miles to the north-east along the coast[3]. Fat salmon that have ceased feeding and are wandering vigorously have been tagged and liberated as caught in traps on the Margaree coast. The individuals go in every direction in the sea, as shown by their recapture wherever there is gear to take them[4,5]. As a whole, however, they are shifted by the water movements. They may be concentrated near the shore by near-surface currents from onshore winds, or concentrated near the mouth of the estuary by the return subsurface current that replaces the sea water entrained in the outflow. They are shifted both offshore and onshore as well as to and fro along the coast by wind currents. Native Margaree salmon are thus bandied about by the weather, and in this way, as well as by wandering, become widely dispersed, as was shown by recaptures of individuals from a lot of more than 30,000 that were marked by fin-clipping when they were descending as smolts in 1938. Some of these were tagged as fat 3-sea-year fish in 1941 from various nets along the coast. Recaptures made in the sea showed movement only away from the river as it happened, and the only recaptures in the river were of fish that had been in the concentration close to the mouth of the estuary[4]. It must be understood that salmon do not readily enter the Margaree estuary, few of the fish that begin to wander vigorously in June being taken in the river before August or September in most years. There is nothing to prevent them entering, and they might let themselves be carried in with flooding tide and remain.

The young Margaree salmon become smolts in the spring and descend to the sea after two years in the lower warmer parts of the river system and after three years in the upper cooler parts. They descen when it becomes warm enough for them to be quit active and when light and low water do not kee them so close to the bottom that they are stimulate to head and swim upstream. Their behaviour i tidal waters with plenty of room can be observe when they are in the broad and shallow estuar before being carried out in the stronger currents an deeper water of spring tides. They are to be see dispersed over the bottom, each one occupying station and feeding on passing plankton while stem ming the tidal currents that fluctuate in strengt and change in direction every six hours or so. I may safely be presumed that they do this where the are carried by the estuarial outflow to deep wate in which they descend out of sight.

Knowledge of where they settle when carried se ward in the outflow and dispersed is necessarily ver limited. Fishermen occasionally catch salmon o their baited hooks when fishing in the outflow an at depths as great as thirty fathoms or more. Onl when the salmon cease feeding and, on wanderin become concentrated near shore or in the outflow i it profitable to fish for them. Few of them do th as grilse after a year in the sea. Most of them do after two years, and a considerable number afte three years. The nets used have a mesh size suitabl for capture of these larger fish. When those marke as smolts in 1938 appeared as 2-sea-year fish in 194 they were at first found only in the outflow and fro six to twenty miles along the coast from the estuar mouth. They were more abundant near the inn than near the outer end of this zone, which evidently where they had settled as smolts. Th river had, as usual, declined in flow during June 1938 when they descended, which meant that th 3-year-old smolts from upper cooler waters woul not on the whole be carried as far seaward as th 2-year-old smolts. Correspondingly, as study of th scales of the fish showed, the former dominate among the salmon taken at the inner end of th zone of their primary distribution in the sea an the latter dominated at the outer end. As the fishin season progressed, this difference decreased as result of mixing from wandering of individuals t and fro in every direction. A similar situatio existed in 1941, when these marked native Margare salmon appeared as 3-sea-year fish. However, the appeared later in the season than the 2-sea-year fis had done and along a greater part of the outflov These facts indicated that the 3-sea-year fish ha settled farther offshore in deeper and cooler wate where they would mature more slowly and be expose later in the season to vernal warming. Where the settled had determined their remaining a longer tim in the sea and reaching a greater size. On the whol this was farther from the estuary mouth, so th the 3-sea-year fish had a smaller percentage th had been 3-year-old smolts than had the 2-sea-ye fish. The relative distribution of 3-year-old an 2-year-old smolts along the outflow as shown by th adults varies with the river discharge during th period of their descent. In 1933, the dischar fluctuated greatly and did not decline very markedl It has been found that, as a result of this, 3-year-ol smolts were not dominant among the salmon fro the smolts of that year that were taken near th estuary mouth in 1935 as 2-sea-year fish and in 19 as 3-sea-year fish. Ordinarily they would be domina among salmon taken near the estuary mouth, as w true for the 3-sea-year salmon of 1935 and for th

-sea-year salmon of 1936, which were from smolts descending in 1932 and 1934, respectively, when the river discharge declined steadily and markedly. With marked decline, the 3-year-old smolts in rriving late would not find where they settled near he estuary mouth the ground already occupied by so many younger, but not smaller, fish.

In conclusion, it may be stated that, while individual fish may quickly reach and enter the iver (one even returning from Newfoundland), ntrance of the adult stock into the estuary depends on the whole upon the fish being carried into the stuary or close to its mouth. Also, ascent of he river from the estuary depends, as is well known, upon freshets, which stimulate the fish to greater activity.

PAPER CHROMATOGRAPHY AS A TOOL FOR MOSQUITO TAXONOMY: THE *CULEX PIPIENS* COMPLEX

By Dr DON W. MICKS

Laboratory of Medical Entomology, Department of Preventive Medicine and Public Health, University of Texas Medical Branch, Galveston

THE taxonomy of mosquitoes is well advanced by comparison with that of most groups of insects, and yet there remains a number of problems which cannot be solved by ordinary taxonomic methods. This is particularly true of the *Culex pipiens* and *Anopheles maculipennis* complexes, where recognition characters are insufficient to distinguish between the various members of the group. Recently, the *Culex pipiens* complex has been the object of intensified and concerted efforts on the part of taxonomists, geneticists and others, in order to establish the exact relationship of the mosquito populations which comprise this group[1]. It is apparent, however, that neither taxonomic nor biological differences have been sufficiently significant to provide an accurate basis for distinguishing between members of the complex. Without adequate morphological discontinuities, it is obvious that the problem must be approached with additional methods.

To provide a more discriminating tool for mosquito taxonomists and to learn more about mosquito–parasite relationships, we initiated the biochemical approach to the problem with the application of paper chromatography to the study of mosquito extracts[2]. It was possible to demonstrate that different genera of mosquitoes exhibit markedly different patterns of free amino-acids. The purpose of the present communication is to show that, with a revised and simplified technique, it is possible to demonstrate consistent biochemical differences between members of the *pipiens* complex used in this study.

American *Culex pipiens* (Illinois), *C. fatigans* (California) and *C. molestus* (Germany) were maintained as laboratory colonies, whereas European *C. pipiens* were collected as adults in Pavia, Italy. The adults of all species except the latter were used at two to three days of age, unfed. For some experiments, mosquito extracts were prepared according to previously described methods[2] for obtaining free amino-acids. When whole mosquitoes were used, the wings and legs were removed and the bodies boiled for two minutes in distilled water to coagulate the protein. Excess water was removed and the bodies mashed on the chromatographic paper with a glass rod. Four adult female mosquitoes were always used to make one preparation. The spot produced by each specimen was allowed to dry before adding the next in order to keep the material confined to a small area. Propanol and 1 per cent ammonia (2 : 1) was the solvent used for all one-dimensional chromatograms, and the different strains were always run in duplicate. Two-dimensional chromatograms were run with phenol as the first solvent and butanol – acetic acid and water (4 : 1 : 1) as the second. Whatman No. 1 filter paper was used for all chromatograms. All sheets were allowed to remain in the solvent for 16 hr. at 22–25° C. Those run in phenol were dried in the oven at 80° C., whereas all other chromatograms were allowed to dry at room temperature. All were sprayed with 0·2 per cent ninhydrin in water-saturated butanol.

Chromatograms of four extracts of each member of the *pipiens* complex used, as well as those of whole boiled mosquitoes, revealed consistent differences in their ninhydrin-positive patterns. One-dimensional chromatograms in propanol – ammonia showed eleven ninhydrin-positive spots for all species. As can be seen in Fig. 1, the patterns representing each of the forms studied are similar except for spots 6, 7, 8 and 9, where there are striking differences in the density of colour. Spot 6, which does not photograph well due to its yellow colour, is always more intense in *fatigans* than *pipiens*. On the other hand, spots 7, 8 and 9 are consistently darker in the latter species. The pattern of *molestus* is similar to that of *fatigans*, except the latter exhibits less intense spots, 7, 8 and 9.

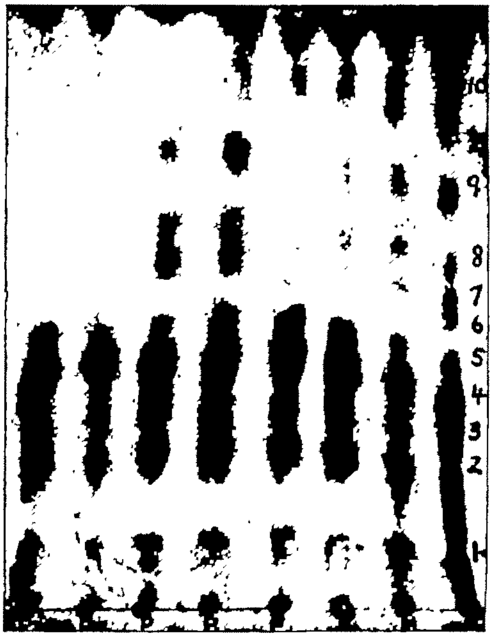

Fig. 1. One-dimensional chromatogram of specimens of European *C. pipiens*, PW; American *C. pipiens*, P; *C. fatigans*, F, and *C. molestus*, M, run in duplicate

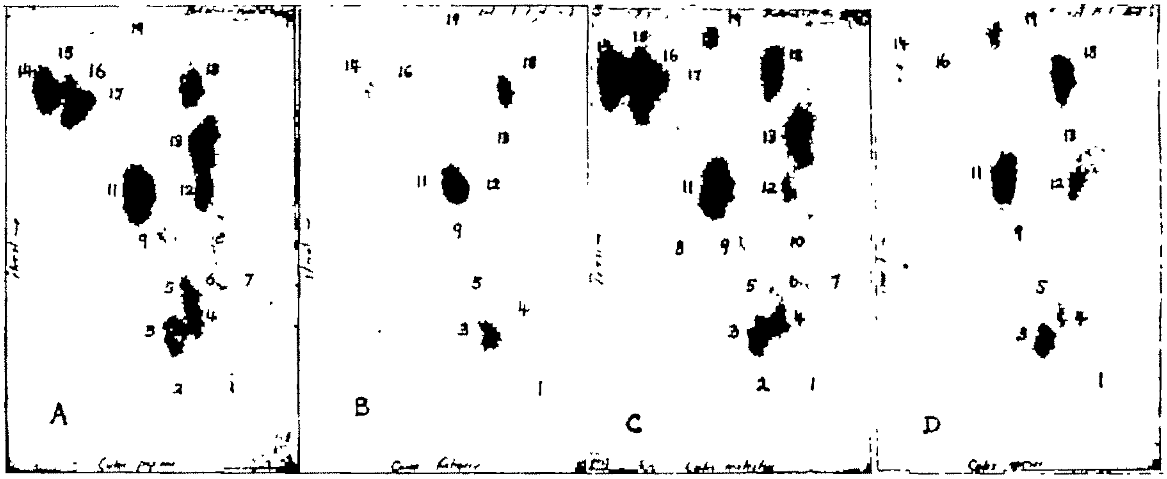

Fig. 2. Two-dimensional chromatograms of extracts. (*A*) *C. pipiens* (American); (*B*), *C. fatigans*; (*C*), *C. molestus*; and (*D*), *C. pipiens* (European)

The European *pipiens* present an interesting pattern inasmuch as they show the greatest amount of proline (spot 6) of all the forms studied, and yet spots 7, 8 and 9 are practically absent. The extracts presented essentially the same pattern.

For better and more accurate comparison of certain ninhydrin-positive substances, two-dimensional chromatograms were run with extracts. Fig. 2 compares chromatograms of the different members of the *pipiens* complex studied. At the level of concentration used, sixteen to nineteen spots representing free amino-acids appeared on chromatograms of extracts of the four different forms. Actually, fewer ninhydrin-positive areas than this are seen in Fig. 2, since some spots developed after the photographs were made. Although in general the patterns are similar, striking differences in amino-acid concentration are seen in certain areas as judged by the density of colour. For example, spots 2 and 7 do not appear on the chromatogram of European *pipiens*, and the latter spot is also absent in *fatigans*. One of the most significant differences may be seen in spot 19, which is markedly more dense in European *pipiens* in spite of the relatively low concentration of other amino-acids.

It appears from the results thus far obtained that paper chromatography may be an extremely useful taxonomic tool, particularly when there are no good morphological recognition characters for the species involved. In fact, it may well be that such biochemical methods as chromatography and infra-red spectrophotometry[3] present the most consistently accurate means of distinguishing between populations of mosquitoes within a complex.

Whole mosquitoes provided material equally as good as extracts for one-dimensional chromatography and without the time-consuming methods and special equipment required for the latter. This method is thereby a simplification of that previously used[2]. Far less material is required than for extracts, since a chromatogram can be run with as few as four specimens. Furthermore, the propanol–ammonia solvent does not have the objectionable characteristics of phenol and the chromatograms dry rapidly.

It is not yet known how the ninhydrin-positive patterns vary with the age of the specimens used. On a few occasions adults of two weeks of age have been used with no apparent alteration in the characteristic pattern. The European *pipiens*, however, which have all been collected from the basement of a building during the winter, were probably one to two months old. The relatively small quantity of ninhydrin-positive substances seen in the chromatograms of these specimens, therefore, may reflect a lowered metabolic rate or a partial depletion of certain amino-acids. Although all the forms used in the present study contain the same amino-acids (including glutamine) as previously determined with other strains[2], no attempt has yet been made to identify the substances which appear on the one-dimensional chromatograms.

This work on members of the *Culex pipiens* complex is being continued and extended to the *Anopheles maculipennis* complex.

The work described in this communication was carried out under a Fulbright Research Grant. I am indebted to the Istituto di Zoologia, Università di Pavia, for the use of facilities and equipment. Thanks are due to Dr. J. B. Kitzmiller, of the University of Illinois, for kindly supplying three strains of *Culex* used in this work.

NEW TYPES OF INTERFERENCE FILTERS OF GREATER AREAS AND HIGHER CONTRAST

By A. HERMANSEN

Physics Department, Royal Veterinary and Agricultural College, Copenhagen

IN a previous communication[1] the principles were outlined for the production of interference filters $ML_{2m}M$ of the Fabry–Perot type with transmission bands at definite wave-lengths (M means silver layers and L_{2m} means a layer of a dielectric with low index of refraction and with an optical thickness of $2m. \frac{\lambda}{4}$). Briefly, the method consists in measuring the thickness of the dielectric layer during evaporation by measuring in reflexion polarimetrically the phase difference $\Delta = \delta_p - \delta_s$ of the components of the electrical vector parallel (E_p) and perpendicular (E_s) to the plane of incidence at a definite angle of incidence of 75°.

During the past three years, this method has been further developed both theoretically and experimentally, and has been used to control the production of new types of interference filters, especially compound interference filters $M'L_{2m}M''L_{2m}M''L_{2m}M'$ with four silver layers and three dielectric layers.

A new evaporation plant was built in 1951 for the purpose of production of filters with a diameter up to 25 cm. to be used for astrophysical purposes. The diameter and height of the steel bell jar were 60 cm. and 80 cm., respectively. The evacuation of the container was carried out by a 9-in. silicone oil diffusion pump. The filter blank (glass plate) was rotated during evaporation by a small motor placed outside the container, by means of magnetic coupling acting through a brass plate. The distance between the evaporation source of the dielectric and the centre of the filter blank was 68 cm. By this arrangement it has been possible for a filter up to 25 cm. in diameter to obtain a constant thickness of the dielectric layer with an accuracy better than 0·5 per cent.

On the steel bell jar were welded side tubes carrying plane windows at such angles that a perpendicular transmission of the polarized light beam was secured. By this arrangement the polarimetrical quantities $\Delta = \delta_p - \delta_s$ and $\tan \Psi = \rho_p/\rho_s$ resulting from reflexion at the filter layers can be measured directly during the evaporation and employed for control of the thickness of the dielectric layers[1]. In the green–yellow spectral region these polarimetric measurements can be carried out visually by means of a $\lambda/4$-mica plate (Senarmont compensator) combined with a half-shade arrangement. Recently, however, a photoelectric method due to Clegg, Archard and Taylor[2] has been adopted. By this method, using a rotating analyser and a Wollaston prism, it is possible to read Δ and Ψ directly without use of either compensator or half-shade arrangement and to measure in the infra-red as well as in the visible.

For most of the filters cryolite was chosen as a dielectric, because of the experimental difficulties of using magnesium fluoride, due to its higher melting point. However, the optical properties of cryolite depend greatly upon the conditions of evaporation, especially the index of refraction, which depends upon the speed of evaporation (rate of growth of the layer). With a rapid evaporation, a value of n as low as 1·27 will result. With a very slow evaporation (more than 1–2 hr.) n turns out to be as high as 1·34. The index of refraction is determined by measurements of $\Delta_{\text{min.}}$ and $\Delta_{\text{max.}}$ during evaporation.

Only with very slow evaporation can a stable interference filter be made with cryolite as dielectric material.

Magnesium fluoride is more difficult to evaporate in the rather large quantities required by this apparatus. Again, with rapid evaporation n may be as low as 1·28 (measured in vacuum). However, a few hours after the filter has been removed from the container, n increases to 1·38 and a stable filter results.

Interference filters of the Fabry–Perot type $ML_{2m}M$ have the disadvantage that about 0·5 per cent or more of light with a wave-length far from the transmission band passes through the filter. The contrast is given by

$$\frac{I_{\text{max.}}}{I_{\text{min.}}} = \left(\frac{1+R}{1-R}\right)^2 \text{(at } R = 0{\cdot}85\text{; } \frac{I_{\text{max.}}}{I_{\text{min.}}} = 152\text{)}. \quad (1)$$

Dufour[3] has developed a theory for filters with three silver layers, $M'L_{2m}M''L_{2m}M'$. The contrast factor of such a filter is about 2000 (at 5500 A.). However, for many practical purposes the contrast factor is still not high enough.

For these reasons it was decided to try to construct filters of a still more complicated type $M'L_{2m}M''L_{2m}M''L_{2m}M'$, consisting of four silver layers and three dielectric layers. For such compound filters it is important to know what thicknesses of the silver layers M' and M'' will give optimum conditions. In the theory, the following notations are used: R_2 and T_2 are the reflecting power and the transmitting power of the central silver layers M'', and δ_2 and β_2 the phase shifts at reflexion and transmission, respectively, at normal angle of incidence of silver layers M''. R_1 and T_1 are the reflexion and transmission power of the outer silver layers M'. Introducing the important quantity

$$\sigma \exp i\alpha = 1 - \frac{T_2}{R_2} \exp i2(\beta_2 - \delta_2),$$

it can now be deduced from the fundamental equations for thin films that the transmission as a function of wave-length $I(\lambda)$ is given by:

$$I(\lambda) = \frac{(T_1T_2)^2}{|\{1 - R.\exp(-iy_1)\}^2 - R_2.\exp(-iy_2)\ \{1 - \sigma R.\exp(-i(y_1 - \alpha))\}^2|^2}, \quad (2)$$

$$\text{where } R = \sqrt{R_1R_2}; \quad y_1 = \frac{4\pi d_1 n}{\lambda} - \frac{(\delta_1 + \delta_2)\pi}{180}; \quad y_2 = \frac{4\pi d_2 n}{\lambda} - \frac{2\delta_2.\pi}{180};$$

d_1 is the thickness of the outer dielectric layers and d_2 that of the centre dielectric layer.

If $y_1 = y_2$ and if the approximation $\alpha = 0$ is made, it can be deduced from (2) that $I(\lambda)$ will only have one peak (of a definite order) if the relation

$$2R_1(R_2.\sigma)^2 + \sqrt{R_1R_2}\,(1 + (R_2\sigma)^2 - 6R_2.\sigma^2) + 2\sigma R_2 > 0 \quad (3)$$

is satisfied. If this quantity is negative, as in the case of four silver layers of equal thickness, more peaks (of the same order) will result (Fig. 1, D). If only one peak is present, the peak transmission $I_{\text{max.}}$ and the contrast factor $I_{\text{max.}}/I_{\text{min.}}$ can be deduced from equation (2):

$$I_{\text{max.}} = \frac{(T_1T_2)^2}{((1 - R)^2 - R_2(1 - \sigma R)^2)^2} \quad (4)$$

$$\frac{I_{\text{max}}}{I_{\text{min.}}} = \left(\frac{(1 + R)^2 + R_2(1 + \sigma R)^2}{(1 - R)^2 - R_2(1 - \sigma R)^2}\right)^2 \quad (5)$$

To compare the applicability of such compound filters $M'L_{2m}M''L_{2m}M''L_{2m}M'$ with filters of the usual type $ML_{2m}M$, some results from numerical calculations will be given. All the quantities occurring in equations (2–5) can be calculated when the index of refraction of the silver layers and of the dielectric

Table 1

λ / $\nu - i\kappa$	t'' / t'	R_4 / $R_1(3)$	$I_{\max}$ (4)	$\frac{I_{\max}}{I_{\min}}$ (5)	σ / a
6560 A. 0 13 − i 4 27	500 A. 205 A.	0 940 0·685	0 41	5·3 × 10^4	1 0225 −0 228°
5500 A. 0 15 − i 3 36	500 A. 225 A.	0 895 0·608	0 34	0·8 × 10^4	1·0422 −0 575°
4360 A 0 17 − i 2 33	500 A. 250 A.	0 788 0 474	0 28	0 5 × 10^4	1·1074 −1 874°

layers and the thicknesses t' and t'' of the silver layers M' and M'' are known. The results are given in Table 1 and in Figs. 1–3.

In Table 1, t' is calculated in such a way that only one peak results (equation (3) equal to zero) and it is assumed that $n = 1·35$.

In Fig. 1 and Fig. 2 intensity (calculated directly from equation (2)) is plotted against wave-length for different thicknesses t' and t'' of the silver layers for the red, and in Fig. 3 for the green, spectral regions. The small negative value of α gives rise to a small displacement of the peak towards the violet compared with the peak of the filters $M'L_1M''$ and $M''L_2M''$ and gives rise to an asymmetrical curve. This asymmetrical curve is most pronounced for a filter with four silver layers of equal thickness (Fig. 1, D). Comparison of Fig. 1 and Fig. 2 shows that the thickness of the inner silver layers t'' has to be somewhat greater than for a filter ML_mM to get a reasonable band-width of such a filter. In these numerical calculations, a table for the addition of complex numbers[4] has been of great value.

Some filters of this compound type for different wave-lengths have been produced, the polarimetric method[1] mentioned being well suited to control the thickness of the three dielectric layers on the base of the filter. The thickness of the silver layers M' and M'' is determined by means of transmission measurements with test plates. The filters produced seem to confirm the theory. Filters (20 cm. × 20 cm.) with peak transmission as high as 0·35–0·40 have been produced having a transmission less than 0·001 at a wave-length 500 A. from the peak (second order).

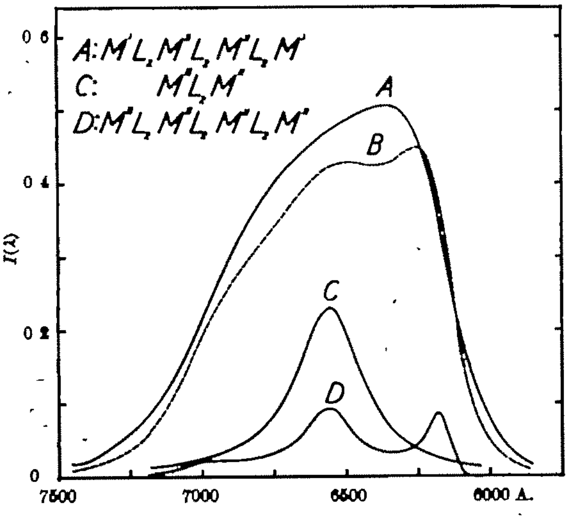

Fig. 1. Calculated curves for compound interference filters $M'L_1M''L_2M''L_1M'$. The thickness of the inner silver layers is $t'' = 400$ A. for all the curves. The thickness of the outer layers t' is: A, 168 A., B, 205 A., and D, 400 A. The thickness of the dielectric layers is chosen in such a way that the filters $M'L_1M''$ and $M''L_2M''$ both have peak transmission at 6560 A. ($R_4 = 0·90$; $T_4 = 0$ 06; $\sigma = 1·0536$; $a = -0·462°$)

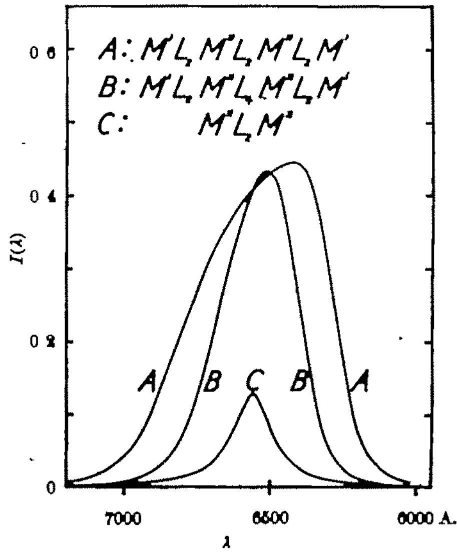

Fig. 2. Calculated curves for two compound interference filters $M'L_1M''L_2M''L_1M'$ and $M'L_2M''L_1M''L_2M'$ compared with the Fabry–Perot filter $M''L_2M''$. $\nu - i\kappa = 0·13 - i\ 4·27$, $n = 1·35$, $t'' = 500$ A. and $t' = 205$ A. The thicknesses of the dielectric layers are chosen in the same way as in Fig. 1

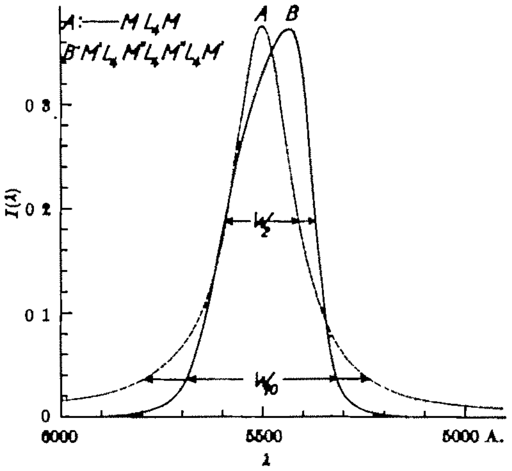

Fig. 3. Calculated curve for a compound interference filter (B) compared with a Fabry–Perot filter (A) with the same peak transmission. $\nu - i\kappa = 0·15 - i\ 3·36$. $t'' = 500$ A., $t' = 225$ A. for the compound filter and $t = 360$ A. for the Fabry–Perot filter. Both filters are of the second order

A more detailed account of this work will be published elsewhere.

I wish to thank Prof. Bengt Strömgren, director at the Royal Astronomical Observatory, Copenhagen, who made the construction of the larger evaporation plant possible. I am also grateful to Prof. Ebbe Rasmussen, the director of this laboratory, for many valuable discussions and for his interest in this investigation; finally, I wish to thank Mr. P. W. Streander for the construction of the apparatus.

Dawn and Dusk Flight of *Drosophila subobscura* Collin

Few records exist of insects with two peaks of activity in 24 hr. Of the many identified species attracted to a light in four years of continuous trapping, only one, a moth *Pterophorus monodactylus*, was caught at two separate times each night[1]. *Aphis fabae* has a double peak of emigrant flight from its secondary host, and this is the result of a complex chain of moulting rhythms, weather influences and flight behaviour[2]. A fall has been observed in the number of *Simulium venustum* in the air when evaporation-rate was high, leaving density maxima at 09.00 and 18.00 hr.[3]. Several species of Drosophilidae have been caught at bait traps with maximum numbers at dusk and dawn both in Europe and America[4-6]; but many factors, including humidity, will affect the area of influence of these traps and hence the number of insects caught and possibly their time of arrival.

Many insects have been caught by suction trap[7] at Rothamsted, but none shows such a striking bi-modal periodicity as the Drosophilidae (several species of *Drosophila* and *Scaptomyza*). Specimen catches for *D. subobscura* on two days of contrasting weather in July and on a dull day in October are recorded in Fig. 1. These density values are absolute and are not artificially stimulated by bait or light; the ordinate is the mean density of insects per *c*. 10,000 cu. ft. of air during the 30 min. abscissa intervals. The depressing effects of adverse weather on aerial density can be seen in the July histograms and the shift in time of flight with a shorter day in the October catch. Despite differences in trapping site, weather, times of year and population density, the two peaks remain quite distinct, with no flight either in complete darkness or bright daylight.

This is curious, because the Schizophora (Diptera), apart from the Drosophilidae, are mainly day-flying insects, and the Drosophilidae have apposition eyes usually associated with good directional vision in daylight; *D. subobscura*, in particular, cannot mate without light, at least in the laboratory[8]. Its crepuscular activity therefore seems anomalous. However, in wild-type *D. melanogaster*—which has a similar periodicity—there is a shift in the spectral sensitivity of the eye to shorter wave-lengths when light intensity is low[9]. This will tend to increase the relative efficiency at dawn and dusk.

Drosophilidae are highly susceptible to desiccation[10], and those that live in humid sub-tropical forests have a more flexible periodicity than species found typically in open country[6].

It is interesting to speculate that *Drosophila* may have become adapted to increasing daytime aridity not by increased resistance to desiccation, as must have happened to most Schizophora, but by increased visual efficiency to low light intensities, together with a shift in flight periodicity to less climatically extreme but darker times of day. In this context the observation on *Simulium venustum* already mentioned is especially interesting.

Further analysis of the observations, now in progress, may reveal how far flight behaviour alone is responsible for the periodicity. Emergence rhythm also may be involved as in *Aphis fabae*, though this seems unlikely as it has a single daily maximum and few virgins were caught; but it may partly explain the difference sometimes found between the morning and evening sex ratios (see Fig. 1).

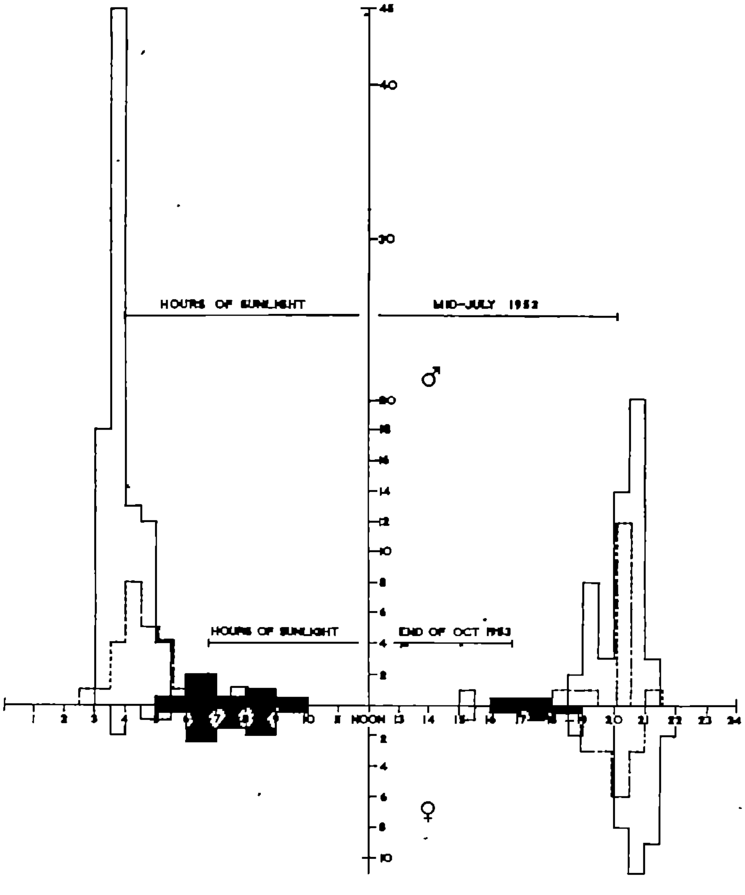

Fig. 1. Numbers of *Drosophila subobscura* caught in a suction trap at Rothamsted, Herts

———: On July 10, 1952, a fine day: the mouth of the trap placed level with the top of a bean crop in a walled garden at Rothamsted Lodge. - - - -: catch of July 23, 1952, a dull day: the trap sited as above. ///////////: catch of October 28, 1953: the trap placed 3 ft. 6 in. above ground-level, in an orchard at Rothamsted Manor House; dull, slight drizzle

We would like to thank Dr. E. B. Basden, of the Institute of Animal Genetics, Edinburgh, for confirming the identification of *D. subobscura*.

An Epizootic among Laboratory Stocks of the Desert Locust, *Schistocerca gregaria* Forsk

D'HERELLE[1] isolated a small Gram-negative bacillus from dead or dying *Schistocerca pallens* Thunb. in Yucatan, Mexico. He considered this organism, which he named *Coccobacillus acridiorum*, to be the etiological agent of a highly virulent disease which was responsible for widespread destruction of locusts in this region. Although he claimed success in locust control by means of the organism, other workers were less successful and the method was finally abandoned. Later, there was some confusion as to the true identity of *Coccobacillus acridiorum*; but Steinhaus[2] states that it is probably related to *Aerobacter aerogenes*.

The Anti-Locust Research Centre, London, recently reported an epizootic among laboratory stocks of *Schistocerca gregaria*, Forsk, in which mortalities were often as high as 80–90 per cent per cage, although not all cages were affected. Ante-mortem, the condition is difficult to distinguish in a crowded cage until shortly before death, when the insect becomes moribund with spasmodic twitching of the appendages. Post-mortem, the integument darkens and the eyes become a deep red; the abdomen and appendages are extremely flaccid and the viscera a viscous mass.

In our experiments the typical disease was found to be serially transmissible by intrahæmocœlic inoculation of healthy locusts with tissue suspensions prepared from dead insects. No evidence of a virus etiology could be found; Seitz and 'Gradocol' membrane (0·70 μ) filtrates of infective tissue suspensions were innocuous. On the other hand, a bacterial etiology was suggested by the facts that blood cultures taken shortly before death almost invariably yielded pure cultures of a Gram-negative organism, and that after death smears of blood or tissue showed Gram-negative bacilli in very large numbers.

There is strong evidence that a non-lactose-fermenting Gram-negative bacillus is the etiological agent of this epizootic disease. Such an organism has been isolated from every case of the typical disease, but in only one of 150 healthy locusts was it found. Intrahæmocœlic inoculation of less than ten of these organisms invariably produces death. Locusts fed on food sprayed with broth cultures c the bacillus showed mortalities of 70–90 per cen and the cannibalization after death by health locusts of insects inoculated with the organism wa sufficient to start an epizootic disease giving rise t a similar mortality-rate.

The identity of the organism has not yet bee established, though it is probably a paracolon. I seems possible that the organism originally isolate by D'Herelle may resemble the causative agent c the disease briefly reported here, and that D'Herelle' organism was afterwards confused with other strain A second Gram-negative lactose-fermenting bacillu was often isolated from dead locusts; but on only on occasion was it isolated from a sick locust prior t death. Massive doses of this organism are neede to kill, and feeding experiments result in mortalitie similar to those resulting from the feeding of foo sprayed with sterile nutrient broth (namely, 5–20 pe cent). This organism, which is probably *Aerobacte aerogenes*, can regularly be isolated from the gut, an must be regarded as a normal member of the gu flora.

It is hoped to publish detailed results of this wor in the near future.

Conception in Prepuberal Mice following Artificially Induced Ovulation and Mating

SUPEROVULATION in prepuberal mice is a recommended procedure for obtaining unfertilized mammalian ova[1]. Experimental results[2] have indicate that, after fertilization, these ova approximate to th viability of ova from spontaneous ovulations.

In previous studies, fertilized eggs were not obtainable from prepuberal donors since sexual receptivit did not accompany ovulation. The present repor demonstrates that administration of gonadotropi hormones can be followed by ovulation, mating an conception. Since, however, conception in prepubera mice has seldom led to pregnancy, fertilized egg from these animals have been transplanted int mature recipients. Such eggs have developed int viable young.

Mice approximately 35–40 days old were given priming injection of pregnant mare's serum, 1 I.U 60 hr. before the desired time of ovulation. A ovulatory injection of human chorionic hormone 1 I.U., was given 13 hr. before the desired time o ovulation. Observations upon conceptions in prepuberal mice are given in the following experiments

These injections were administered to 37 femal mice (Table 1, *A*); strain 129; 34–41 days old 12–17 gm. in weight. At the time of the ovulator injection (4.30 p.m.), each female was caged with an adult male. The following morning, 34 of th 37 females (92 per cent), showed evidence of having mated (that is, presence of vaginal plugs). The 3 females were subjected to laparotomy at 32 hr. afte

Table 1. OBSERVATIONS ON MICE FOLLOWING ARTIFICIALLY INDUCED BREEDINGS

Totals	81	75	71	437	333 (76 „)

* Only right oviducts were examined. Remainder of data includes observations on both right and left oviducts.

ovulation. The right oviducts were excised and all were found to contain eggs. Cleaved eggs were found in 31 of the 34 right oviducts. A total of 188 eggs were isolated, of which 130 (69 per cent) were in the 2-cell stage.

The 31 animals that possessed cleaved eggs in the right oviducts were divided into two groups. One group, 16 animals, was autopsied three and a half days after ovulation and the remainder, 15 animals, were examined eight days after ovulation.

Of the 16 uteri that were excised and irrigated at three and a half days after ovulation 15 yielded 69 eggs. Forty-five eggs (65 per cent) were typical blastocysts. These particular blastocysts were discarded; but we have reported previously[3] that eleven blastocysts similarly produced have been transplanted to a mature recipient. Six of the eleven blastocysts survived through birth and five were raised to maturity. Our experience has indicated that eggs transplanted from prepuberal mice are no less viable than eggs transplanted after spontaneous ovulations.

The 15 animals that were examined at eight days after ovulation showed no indication of uterine implantations. Similar experiments have been repeated many times, and only occasionally (less than 10 per cent of mated animals) has there been evidence of implantation. Although our results demonstrate that induced ovulation and mating is a reliable source of viable, fertilized eggs, these events have not regularly led to implantation in prepuberal mice.

The procedure for obtaining conception in prepuberal mice has been re-tested using mice of strain 129 (Table 1, *B* to *E*). Females in four subsequent samples were managed differently from those in sample *A*, in so far as they were introduced into pens with males 2 hr. before the expected ovulation and allowed to remain for 5 hr. Copulation occurred in 86–100 per cent of the females, and these mated animals were autopsied 24–36 hr. after ovulation. The mean numbers of eggs in four samples (*B–E*) fell between 6·3 and 7·6, and the ratio of eggs that were in the 2-celled stage varied from 47 to 98 per cent. The five samples of prepuberal mice from inbred strain 129 have shown that induced ovulation and mating occurred in 71 out of 81 animals. Recovery of 437 eggs showed that development had been initiated in 76 per cent of the eggs. Conception in prepuberal mice has provided viable fertilized eggs for a variety of experiments.

Transport of Chloride in the 'Symplasm' of *Vallisneria* Leaves

Vallisneria leaves exposed to light show a fairly constant chloride absorption[1]; by secretion into the vacuole, the osmotic value of the cell sap is enhanced. If a part of the leaf is in contact with a chloride solution, the chloride is introduced into the cytoplasm and is translocated through it to the rest of the leaf. The chloride can be accumulated in the vacuoles in any part of the leaf that is exposed to light. If the absorbing zone is in the light and the rest of the leaf, here called the 'free part', in the dark, there is no noticeable transport and all the chloride absorbed remains in the absorption zone. If this zone is in the dark and the free part exposed to light, accumulation in the absorption zone is smaller and that in the free part much larger. This points to a transport in the cytoplasm and a secretion into the vacuoles under the influence of light[2].

A new experiment for studying the transport in the cytoplasm of the parenchyma cells is described here. In the first phase (16 hr.) of the experiment, chloride ions are accumulated in the first zone (2·5 cm.) of the leaf strips (7·5 cm.). Then the leaf strips are put into water, and a redistribution of the chloride over the other zones can be observed. In this second phase the first zone is in the dark and the free part of the leaf in the light. This difference in the exposure to light is essential to get a redistribution. The amount of chloride present in the different zones 2·5 cm. in length was determined after 8 hr. and 24 hr.

REDISTRIBUTION OF CHLORIDE IN *Vallisneria* LEAVES

First phase, uptake during 16 hr. Second phase, redistribution after 8 hr. and 24 hr. Values in the table give the amount of chloride absorbed by 8 leaf zones of 2 5 cm length and 0·4 cm. width

Uptake	Zone 1	Zone 2	Zone 3	Whole strip
	0 002*M* KCl (+ $CaSO_4$) in the light (γCl)	water in the dark (γCl)	water in the dark (γCl)	(γCl)
16 hr.	208	12	5	225
Redistribution	in the dark in water	in the light in water	in the light in water	
8 hr.	189	26	19	234
24 hr.	172	45	16	233

It is apparent from the table that in the first zone chloride is leaking into the cytoplasm from the vacuoles in which it was accumulated before. As this zone is darkened, there is no further secretion into the vacuoles to restore the chloride content. The chloride is transported in the cytoplasm to the other zones of the leaf which are exposed to light and where secretion brings the chloride from the cytoplasm into the vacuoles. The leakage is continued during the 24 hr. of the experiment. It is remarkable that the chloride contents of the whole leaf strip remain unaltered, no chloride being lost to the outer solution; only the distribution is changed by changing the exposure to light of the different zones. The transport in the cytoplasm from cell to cell over a length of 7·5 cm. without loss to the outer solution indicates that plasma connexions between the cells must exist. The cells behave like a 'symplasm'.

This experiment is in good agreement with former results[3] obtained with inhibitors such as potassium cyanide and 2,4-dinitrophenol, and indicates that three distinct processes have to be taken into consideration: uptake in the cytoplasm, translocation through the cytoplasm and secretion from the cytoplasm into the vacuole. The leakage of the vacuoles is a new factor which, though small, is quite definite.

Full details about these experiments will be given elsewhere.

Structural Analogies of Pox Viruses and Bacteria

Dawson and McFarlane[1] reported that the pepsin-digested elementary body of vaccinia reveals a nucleus-like central body surrounded by a membrane. This phenomenon was confirmed by subsequent papers for vaccinia[2,3] and other viruses of the pox group—fowl pox[3,4], neurovaccinia[3], ectromelia[5] and myxoma[3,5]. Pepsin digestion does not interfere with the deoxyribonucleic acid content of the virus, as shown by an earlier report[6]. In analogy to cells of higher organisms and bacteria, the structure containing deoxyribonucleic acid had to be looked for in the central body. Therefore, we attempted to diges specifically the central body by pure enzymes, as we did with the nuclei of rod-shaped and coccoid bacteri (*Escherichia coli*[7] and *Neisseria sicca*[8]).

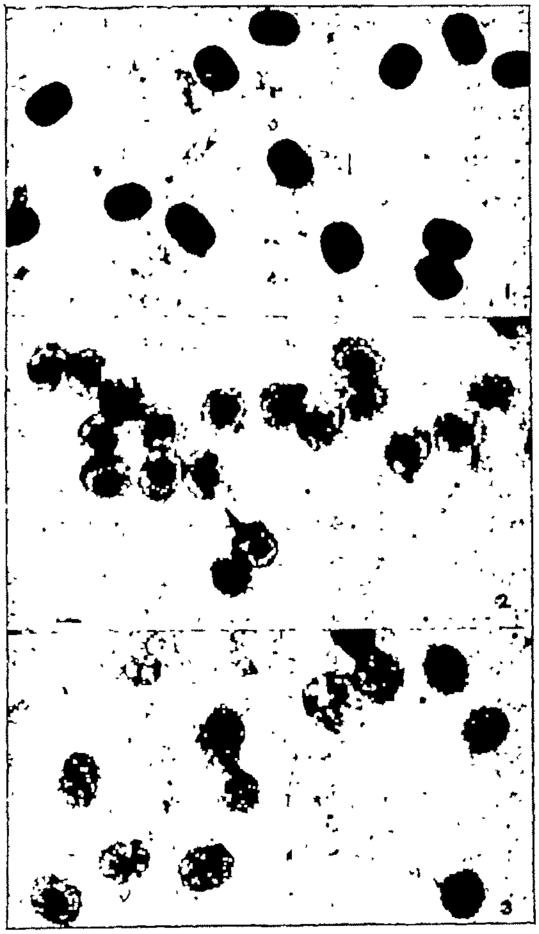

Fig. 1. *Molluscum contagiosum* elementary bodies, untreated. × 25,000

Fig. 2. As Fig. 1, after Chabaud fixation (15 min.) and treatment with crystalline pepsin (0·02 per cent, pH 2·0, 37° C., 2 hr.)

Fig. 3. As Fig. 2 after further treatment with crystalline deoxyribonuclease (0·1 per cent, *M*/15 phosphate buffer pH 6·0, 37° C., 30 min.) followed by a second pepsin treatment as above

Elementary bodies of *Molluscum contagiosum* taken from specific lesions by dabbing[9] (Fig. 1) were fixed in Chabaud solution and treated with crystallized pepsin at pH 2. As in other pox viruses, most of the elementary bodies were degraded and showed a more or less opaque central body of varying size and shape (Fig. 2). Earlier findings[1] that the central bodies of pepsin-treated virus particles become less opaque by treatment with deoxyribonuclease could not be confirmed, because of the variable density of these bodies. But when the deoxyribonuclease treatment was followed by a second pepsin treatment, the mass of the central body was hydrolysed, leaving an almost empty membrane (Fig. 3), thus showing that pepsin will not digest the proteins of the central body unless the protection afforded by deoxyribonucleic acid is rendered ineffective by the depolymerizing action of deoxyribonuclease; this finding was borne out by similar observations on deoxyribonucleoproteins of higher organisms (see ref. 10).

So far as the effect of these enzymes is concerned, there is obviously no dissimilarity between the central body of pox viruses and the nuclear structure of bacteria[7,8]. The virus membrane left after enzyme treatment resembles in many respects the empty wall of a bacterial cell.

A full report of this work will be published elsewhere[11]. Analogous results were obtained with vaccinia virus[12], in which we have studied the morphological variation of the central body (unpublished work). We acknowledge the assistance of the Deutsche Forschungsgemeinschaft.

Isolation of *Keratinomyces ajelloi* from Soils in Great Britain

Karling[1] first used keratinaceous materials for the isolation of keratinophilic chytrids from soil and water. Similar techniques for the isolation of other keratinophilic fungi from soil have since been devised by other workers. Thus, Mandels *et al.*[2], Cooke[3] and Ajello[4] have also isolated *Microsporum gypseum* from various soil samples in the United States. Belgian soils examined by Vanbreuseghem[5] yielded no known dermatophytes, but did reveal the presence of a keratinophilic fungus which Vanbreuseghem placed

Fig. 2. Unattacked hairs on sterile control plates after 8 days. (4/7 natural size)
Fig. 3. Perforating organ of *K. ajelloi* penetrating hair shaft. Dark background photograph (× *c.* 95)
Fig. 4. Macroconidia produced by *K. ajelloi* growing on hair from soil plate. (× *c.* 190)

ı a new genus, *Keratinomyces*, and gave the specific ame of *K. ajelloi*. This organism was also isolated y Ajello[4] from one sample of soil from Tennessee nd two samples from Georgia, out of a total of 16 soils collected from different localities. In this ommunication *K. ajelloi* is recorded for the first time ı Great Britain, having been isolated from sixteen ut of nineteen soil samples collected in different calities.

Soil samples were collected from the top two inches nd placed in sterile tins. The method used for the olation of *K. ajelloi* was the same in principle as hat described by Vanbreuseghem[5]. For each sample x Petri dishes were half filled with soil; three of hese were autoclaved at 20 lb. per sq. in. for 20 min. nd served as controls. Strands of autoclaved hair ere placed on the surface of the soil, and the latter moistened with sterile distilled water. The cultures were incubated at 20° C. and examined daily. After 7–14 days vinaceous buff-coloured[6] mycelium covered the strands of hair on non-sterile soil (Fig. 1); but no growth was observed on sterile control plates (Fig. 2). Hairs from the experimental plates were removed and mounted in cotton blue-lactophenol. Microscopical examination of the hairs showed various stages in digestion and penetration of the hair shaft by fungal perforating organs of the type described by Vanbreuseghem[7] (Fig. 3). Abundant macroconidia were produced by the fungus growing on the hairs (Fig. 4).

Pure cultures were obtained by transferring spores to Sabouraud's glucose agar slopes. Isolates resembled in every respect those of *K. ajelloi* isolated from Belgian soils and described by Vanbreuseghem. Colonies growing on Sabouraud's glucose agar were pale yellow-orange[6] in colour and lanose in texture and produced a dusky drab-coloured[6] diffusible pigment, although in some strains pigment only developed as the colonies aged. All strains produced abundant, multiseptate, fusiform macroconidia.

Effects of Antibiotics on Carbon Dioxide Production in Soil

THE fate of antibiotics in soil is of great interest, partly on account of the possible importance of antibiotic substances in the development of the associations in the natural micropopulations, partly on account of the aspects of using antibiotics in the control of soil-born plant pathogens.

Gottlieb *et al.*[1] have shown that basic antibiotics like streptomycin are rapidly inactivated in soil by adsorption by the clay and the organic matter. They also found that the activity of two amphoteric antibiotics, aureomycin and terramycin, are dependent of the hydrogen ion concentration of the soil; generally they are acting as bases, being adsorbed by the clay. A neutral antibiotic, chloromycetin, was rapidly inactivated, probably by biological agencies. Jefferys[2] found that the rate of inactivation of penicillin and eight other fungal antibiotics varied from soil to soil, and considered this to be mainly an effect of pH on biological activity. Pramer and Starkey[3] found that decomposition of streptomycin occurred in soil and succeeded in isolating a species of *Pseudomonas* capable of decomposing streptomycin.

The effects of high concentrations of antibiotics on the complex micropopulation of the soil has been studied by determination of the evolution of carbon dioxide (by Petersen's method[4]) as a measure of the rate and extent of biological activity in soil. Five antibiotics were used: penicillin, chloromycetin, terramycin, streptomycin and aureomycin. Carbon dioxide from triplicate flasks was determined during a 14-day period at 25° C. In each of the experiments a normal Danish field soil (pH 6·5) was used, air-dry, with addition of 16 per cent water and 0·5–0·7 per cent of each of the five antibiotics mentioned above.

The results are shown in Figs. 1 and 2. Penicillin, chloromycetin and terramycin brought about a slight inhibition in the evolution of carbon dioxide, in the first 24–72 hr., perhaps corresponding to the lag phase. The inhibition was followed by a great rise in the production of carbon dioxide, which during the whole period amounted to approximately twice the production of the control experiments (Table 1). The excess over control corresponds to 10–20 per cent of the carbon in the amounts of the three antibiotics added.

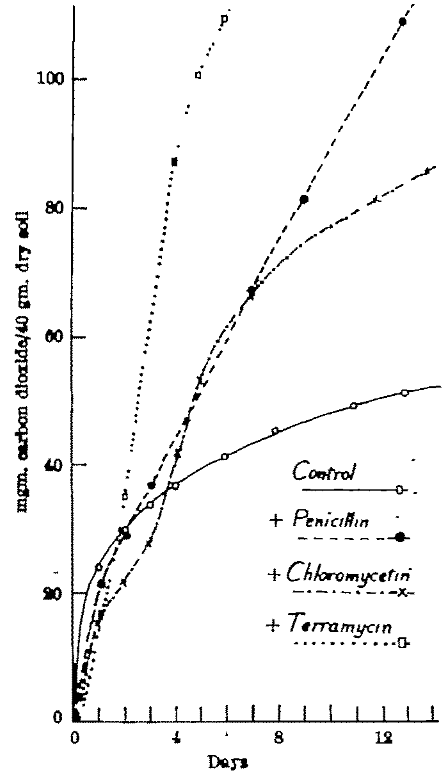

Fig. 1

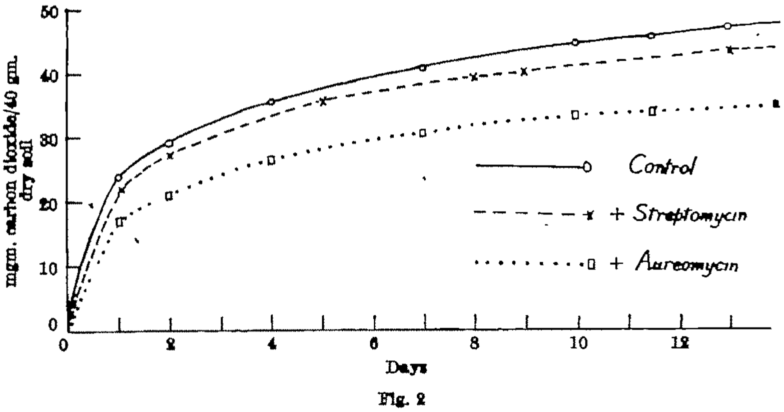

Fig. 2

The experiments with aureomycin and streptomycin showed a slight but persistent inhibition during the 14-day period, perhaps on account of the amounts added, which probably exceeded the adsorption capacity of the soil. These experiments thus indicated that there was no decomposition of these two substances within the experimental period.

Plate cultures from the soil used in the three first experiments were made on a mineral agar plus the corresponding antibiotic as the only source of carbon. In all three cases soil fungi were isolated which were

Table 1. EVOLUTION OF CARBON DIOXIDE FROM THE SOIL
(mgm. carbon dioxide per 40 gm. dry soil)

		Penicillin	Chloromycetin	Terramycin
Control		51·2	47·8	56·8

Excess	Carbon dioxide (mgm.)	61·4	37·4	91·9
	Carbon (mgm.)	16·5	10·2	25·1
	Per cent of carbon added in the antibiotic	14	10	20

able to grow in liquid synthetic medium with the corresponding antibiotic as the only source of carbon. The following types were found: Penicillin-exp.—*Penicillium* sp., *Fusarium* sp.; Chloromycetin-exp. —*Penicillium* sp.; Terramycin-exp.—*Penicillium* sp.

This work shows that fungi play an important part in the decomposition of antibiotics in soil.

Nutritive Value of Lucerne Protein Concentrates, fed with and without Cholesterol

THE possibility of large-scale extraction of protein concentrates from green leaves has been raised by several workers[1]. Machinery for squeezing juice from crushed leaves has been developed, and a protein concentrate is obtained from this juice by precipitation. Little work has, however, been carried out on the nutritive value of these protein concentrates. Carpenter *et al.*[2] have shown a crude preparation from grass to be superior to groundnut meal when fed as a supplement to a low-protein cereal diet for chicks and rats. Davies *et al.*[3] found purified preparations from cocksfoot to have biological values of 46 and 61 when fed as the sole protein to rats.

We have found that lucerne is one of the most promising crops for protein extraction, and the nutritive value of lucerne concentrates has been studied in a number of experiments. Reasonable growth was obtained when a lucerne/grass protein concentrate was fed as the principal protein in a practical chick ration (18·8 per cent crude protein), in which 2·5 per cent of yeast was included[4]. However, lucerne protein concentrate has been found to be inferior to fish meal when added as the sole supplementary protein to rations composed of cereal products, minerals and concentrated vitamin supplements (15·1–16·3 per cent crude protein).

In discussion with Dr. J. Duckworth, it was suggested that the low nutritive value to chicks of lucerne protein concentrates might be due to a factor similar to that found in lucerne meal by Peterson[5], the effect of which was reduced by the addition of cholesterol to the rations. Using the gross protein value technique[6] the nutritive value of lucerne protein has been further studied.

In all trials, each of three replicates of each treatment consisted of twelve Rhode Island Red × Light Sussex pullets. These were reared from day-old on a diet complete in all known nutritional requirements, but deficient in protein. At 14 days old they were put on to the test rations, and live-weight gains and food consumption measured during the following fourteen days. The test rations were based on a mixture of cereal products, yeast, whey, minerals, vitamin concentrates of A, B_2, B_{12}, D and E and penicillin, to which were added either starch to give the 'cereal' control ration, casein and starch to give the 'casein' control ration, or protein concentrates and starch to give the 'lucerne protein' rations. Oatfeed was added to all rations to balance fibre contents, and calcium and phosphorus were also balanced. Cholesterol, when fed, was added to make up 0·3 per cent by weight of the ration. The protein concentrates were prepared by heat precipitation (80° C.) from lucerne juice at normal *p*H, with roller drying at 120° C. of the resulting coagulum.

Table 1

Supplementary protein source	Percentage crude protein	Mean weight gained in 2 weeks (gm.)	Protein utilization*	Gross protein value†
Trial A				
'Cereal' control	8·0	37·4	—	—
'Casein' control	11·2	91·8	6·53	100
Lucerne protein	11·3	63·8	3·69	57
Lucerne/grass protein	11·1	68·0	4·23	67
Lucerne protein + cholesterol	11·3	77·3	4·83	74
Lucerne/grass protein + cholesterol	11·2	72·5	4·58	70
Trial B				
'Cereal' control	9·9	40·2	—	
'Casein' control	13·6	109·0	5·03	
Lucerne protein + cholesterol	13·3	95·8	4·46	
Lucerne/grass protein + cholesterol	13·0	86·1	4·09	
Trial C				
'Cereal' control	8·1	43·2	—	
Lucerne protein + cholesterol	11·2	85·2	4·95	

* Gain in weight over 'cereal' control per gram of supplementary protein consumed.

† Least significant difference (5 per cent level) = 6·2.

In trial *A*, lucerne protein (48·4 per cent crude protein) and lucerne/grass protein (42·8 per cent crude protein), both fed with and without cholesterol, were compared with 'cereal' and 'casein' controls. In trial *B* the same samples of protein concentrates, both fed with cholesterol, were compared with the 'cereal' and 'casein' controls, all at protein-levels approximately 20 per cent higher than those of trial *A*. Trial *C* adds evidence on the nutritive value of the lucerne protein sample fed with cholesterol.

The results (Table 1) show that in trial *A* the gross protein values of lucerne and lucerne/grass protein concentrates were higher than that of groundnut meal with a value[6] of 50. The addition of cholesterol raised the gross protein values to nearly that of soya-bean meal with a value[7] of 76. The amounts of the lucerne protein rations consumed were less than those of the casein rations, possibly due to the lower palatability of the former.

It appears that the nutritive value of the lucerne protein concentrate was depressed by a factor, possibly a saponin[8], which was inhibited by cholesterol. Work is in progress on the removal of this factor from protein concentrates, and on other methods of purification. Herbage species other than lucerne are also being studied.

Pentoses associated with Jute α-Cellulose

Sarkar and co-workers[1] claimed to have shown that jute α-cellulose does not contain any pentose; we showed[2], however, that xylose and arabinose are present, and this was confirmed by Adams and Bishop[3] by a different method. Recently, Mazumdar and Sarkar[4] have suggested that there is an inherent defect in the formic acid method[5] adopted by us for this purpose. As required by them, the chromatogram of α-cellulose prepared from different jute holocelluloses[6] with 17·5 per cent sodium hydroxide is reproduced in Fig. 1 to show that α-cellulose contains xylose and arabinose.

The finding of Mazumdar and Sarkar[4] that glucose hydrolysed by formic acid gives two spots has already been pointed out by us in the case of glucuronic acid[2]. The extra spots are presumably due to formates[7], which could be easily hydrolyse if the hydrolysate is purified by repeated boilin with water and drying[8] (compare G and G_1 in Fig. 2). We have already stated[2] that the extra spot could b readily differentiated from that given by pentose by colour developed with aniline oxalate reagent nevertheless, they find[4] one extra spot the colou and position of which are different from those o xylose and arabinose, which they attribute to thes sugars although we have repeatedly pointed out that these sugars were chromatographically separate and chemically identified and that the chromatogram was certainly 'over-run' (108 hours)[2]. Recently, b using the published formic acid treatment, Adam and his school[9], of the National Research Council Canada, have found xylose very readily and also trace of arabinose in jute α-cellulose. The formi acid method, therefore, has no inherent defect.

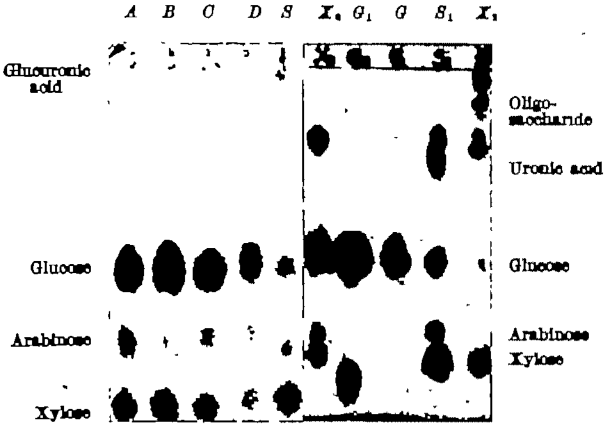

Fig. 1 Fig. 2

Fig. 1. Chromatogram in moist *n*-butanol for 108 hr. on Whatman No. 1 filter paper hydrolysed with formic acid (85 per cent) 3 hr. *A*, Chlorine dioxide α-cellulose; *B*, Cross and Bevan α-cellulose; *C*, Norman and Jenkins α-cellulose; *D*, chlorite α-cellulose; *S*, reference sugars—glucuronic acid, glucose, arabinose and xylose

Fig. 2. Chromatogram in *n*-butanol/acetic acid/water (4 : 1 : 5) for 96 hr. in Whatman No. 1 filter paper

X_1 and X_2, eight times (10–5 per cent) sodium hydroxide treated chlorite α-cellulose, hydrolysed with 85 per cent formic acid for 12 min. and 3 hr., respectively; G and G_1, glucose hydrolysed with formic acid (85 per cent) for 12 min., with and without proper purification, respectively; S_1, reference sugars—galacturonic acid, glucose, arabinose and xylose

The statement by Mazumdar and Sarkar[4] tha jute α-cellulose must contain less than 1 per cen furfural to free it from traces of xylose is open t criticism, as their furfural values[4] of the α-cellulos prepared by a 9·3 per cent solution of sodium hydroxid as well as by their slightly modified method (both o which they claim[4] to be free from pentosan) are 1·4 and 1·23 per cent, respectively. This would appea to mean that α-cellulose prepared by both thes methods and also by the A.C.S. method (2·55 pe cent furfural) contains pentose and supports ou findings.

Furthermore, regarding the proposed extra alternat arbitrary washings of α-cellulose with 10–5 per cen sodium hydroxide over that of the A.C.S. method we feel that by doing so Sarkar *et al.* are not onl deviating from the accepted definition of α-cellulos but also making something other than α-cellulose, a would be evident from the deterioration in colou and decrease in cuprammonium fluidity of a 0·5 pe cent solution ($D = 10·4$; X_1 and $X_2 = 9·2$) afte these alternate alkali washings. Yet, all the product of chlorite α-cellulose (D) after 1, 2, 4 and 8 alternat alkali (10–5 per cent) washings are found to contai readily detectable xylose and traces of arabinose although the furfural content of the eight-times treated sample (X_1 and X_2, Fig. 2) was 0·75 per cent. Thu pentosans are associated not only with conventiona α-cellulose but also with the product of α-cellulos (after repeated washings with 10–5 per cent sodiu hydroxide) having a furfural content even less tha 1·0 per cent, in contradiction to the later statement of Mazumdar and Sarkar[4].

When the duration of hydrolysis of a polysaccharid is as short as 12 min., besides the simple sugars, oligosaccharides are also expected to be formed, a reported by us previously[2] in the case of jut α-cellulose and shown in Fig. 2. While the detailed nature of the oligosaccharides is under investigation, Adams[10], by using the formic acid method, has also confirmed that oligosaccharides are produced. But comparing our chromatogram (X_1) with that o Mazumdar and Sarkar (X) it can be seen that although in the latter the glucose spot is very prominent, no oligosaccharide is found, which in view of the short time of hydrolysis indicates that their jute α-cellulose is easily hydrolysable to a simple sugar (glucose) without the intermediate formation of an oligosaccharide. We find this difficult to understand, especially as they have not reproduced the chromatogram of formic acid-treated glucose to enable comparison to be made with that of their jute α-cellulose.

The above results therefore support our findings that pentosans are strongly associated with jute -cellulose. Their bearing on the structure of -cellulose is under investigation.

I have some of the α-cellulose prepared in connexion with the communication in *Nature* of December 5, 1953, and will gladly send it to any nterested chemist to verify our finding.

There is little to add to what Meyer has said about pure cellulose (*Nature*, 164, 786; 1949). It is not clear which of Adams's jute fibre and jute straw (in the table) contains xylose and arabinose in the α-cellulose (*Nature*, 172, 28; 1953).

Abdominal Lymphatic Tissue as a Source of Hyperglycæmic Glycogenolytic Factor

It has been stated by Sutherland and de Duve[1] that the hyperglycæmic glycogenolytic factor of the pancreas is formed in the alpha cells of the islet tissue. Presence of an identical factor in the gastric mucosa ed the same workers to suggest that the argentophil cells of the gastric mucosa, a cell-type believed by some investigators[2] to be identical with the alpha cells of the pancreas, might also be the site of formation of this factor. The recent discovery that cobalt chloride selectively destroys the alpha cells[3] but not the argentophil cells[4] has, however, thrown doubt on the morphological relationship of these cells. The specific site of formation of the hyperglycæmic glycogenolytic factor has not yet been definitely established. The investigations reported here appear to throw further light on this controversial point.

Rabbits of both sexes, average weight 1·5 kgm., were used. The hyperglycæmic glycogenolytic factor was extracted from the pancreas of four groups of animals: (*a*) normal rabbits; (*b*) rabbits treated with cobalt chloride (50 mgm./kgm. body-weight as a 5 per cent solution by intravenous injection once a day for two days); (*c*) rabbits treated with a single intravenous injection of 200 mgm./kgm. body-weight of alloxan monohydrate in a 4 per cent solution; (*d*) rabbits rendered diabetic with alloxan as in group (*c*) and then treated with cobalt chloride as in group (*b*). The hyperglycæmic glycogenolytic factor extracted from the pancreas of these four groups of experimental animals was assayed both by *in vivo* and *in vitro* methods[1]. Hyperglycæmic glycogenolytic factor extracts were first incubated with cysteine and dialysed against chloride phosphate buffer.

In the *in vitro* studies, hyperglycæmic glycogenolytic factor activity was determined on rabbit liver slices incubated in chloride phosphate buffer at 37° C. For purposes of comparison of maximal activity, commercial insulin (Lilly) was used. Varying doses of hyperglycæmic glycogenolytic factor extracts were used and the results expressed in milligrams of fresh tissue required to produce half-maximal activity[5]. The results of *in vitro* studies are given in Table 1.

Table 1. Glycogenolytic Activity of Hyperglycæmic Glycogenolytic Factor Extracts of Various Tissues on Liver Slices

Animal	Tissue	Mgm. of tissue required for half-maximal activity
(*a*) Normal	Pancreas	60
	Gastric mucosa	100
	Lymph glands	40
	Spleen	100
(*b*) Treated with cobalt chloride	Pancreas	50
	Gastric mucosa	100
	Lymph glands	40
(*c*) Alloxan diabetic	Pancreas	50
	Gastric mucosa	100
(*d*) Alloxan diabetic and treated with cobalt chloride	Pancreas	50
	Gastric mucosa	100

While histological studies revealed that in the pancreatic islets of rabbits treated with cobalt chloride most of the alpha cells were either degenerated or destroyed, the hyperglycæmic glycogenolytic factor content of these pancreases was found to be at normal levels. These observations are contrary to the claims of Van Campenhout *et al.*[3] and de Duve *et al.*[4]. The hyperglycæmic glycogenolytic factor content of the gastric mucosa from the animals of groups (*a*) and (*b*) were similarly found to be undisturbed. These features naturally raised the question of specificity of the site of formation of the hyperglycæmic glycogenolytic factor in the two organs.

With the view of correlating the existence of this factor in the two different organs studied, a search was made for the presence of some type of cells common to both. In sections of the pancreas and of the gastric mucosa of rabbits, it was frequently observed that lymphatic tissue occurred in both, either as loosely scattered clusters of cells or as regular lymph nodes. The possibility of these cells being the source of hyperglycæmic glycogenolytic factor was therefore considered.

Abdominal lymph nodes, a large group of which is situated near the ileo-cæcal junction in rabbits, and also the spleen, were selected for study, and the hyperglycæmic glycogenolytic factor contents of these tissues were estimated. The results of the *in vitro* studies are given in Table 1. The extract from the abdominal lymph nodes showed marked activity; that of the spleen also showed activity, contrary to the claims of Sutherland and de Duve[1].

In *in vivo* studies, hyperglycæmic glycogenolytic factor from 2 gm. of pancreas from normal rabbits and from rabbits treated with cobalt chloride gave a 30 per cent rise of blood sugar in rabbits. Hyperglycæmic glycogenolytic factor from 2 gm. of abdominal lymph nodes gave 35 per cent rise of blood sugar in rabbits. Previous treatment with cobalt chloride did not alter the hyperglycæmic glycogenolytic factor content of lymph nodes.

Experiments designed to localize the site of formation of the hyperglycæmic glycogenolytic factor show that it is present in pancreas, gastric mucosa, abdominal lymph nodes and spleen of rabbits both of normal and of experimental groups. The destruction of the alpha cells of the islet tissue of the pancreas has no appreciable effect on the hyperglycæmic glycogenolytic factor content of the pancreatic extract, showing that these cells are not involved in the formation of this factor. The presence of the factor in the extracts of abdominal lymph nodes and spleen suggests that its site of origin may be the lymphatic tissues distributed in the various organs studied.

We wish to thank Dr. B. Mukerji for the interest he has taken in this work.

Inhibition of the 'Condensing Enzyme' of *Aspergillus niger* by Magnesium

Stern and Ochoa[1,2] found that magnesium (or manganese) was required for maximum activity of the 'condensing enzyme' (oxalacetate + acetyl-coenzyme A ⇌ citrate + coenzyme A) isolated from pigeon liver, and used an assay system containing 4 μM magnesium chloride per ml. The same or similar systems have been used by others in comparing enzyme-levels in different organisms[3–5] and by us in studies of the 'condensing enzyme' of *Aspergillus niger*[6,7]. In later work with the *A. niger* enzyme, we found that magnesium ions were not required and that they were actually inhibitory. Inhibition of the *A. niger* enzyme by magnesium ions differentiates it from the avian enzyme and suggests that some of the lower specific activities reported for enzyme preparations from other organisms[3,5] may reflect the same phenomenon.

Crude extracts and second ammonium sulphate fractions (0·5–0·6 of 0–0·6 fractions) of fresh *A. niger* mycelium were prepared as previously outlined[6,7]. Crude extracts and second ammonium sulphate fractions (0·4–0·6 of 0·5–0·6 fractions) of lyophilized cells were also used as the source of the enzyme. *Escherichia coli* (0–0·6 ammonium sulphate fraction)[7] was used as the source of transacetylase. Ammonium sulphate fractions were dialysed against phosphate buffer before use. One millilitre of the assay system contained: phosphate buffer (*p*H 7·2), 25 μM coenzyme A, 12 units; oxalacetate, 20 μM; acetyl phosphate, 8 μM; L-cysteine, 4 μM; *E. coli* fraction 0·05 ml., *A. niger* fraction, 0·2 ml. of crude extrac or 0·02 ml. of ammonium sulphate fraction. When indicated, magnesium ions were added as magnesium chloride. Incubation was at 28° for 40 min.

Magnesium was determined spectrographically on dried 1-ml. samples of the complete reaction mixture (without added magnesium ions). Intensities of the magnesium line 2781·4 A. were compared with standards of magnesium chloride using a step sector

Table 1 illustrates the inhibitory effect of magnesium ions (4 μM magnesium chloride) on four different enzyme preparations.

Fig. 1 shows the inhibition of citrate synthesis by different levels of magnesium ions when a second ammonium sulphate fraction of an extract of fresh cells was used as the source of the enzyme. Maximum inhibition (38 per cent) was attained with 4 μM of added magnesium chloride. Further increases, up to five times this level, did not alter the percentage inhibition.

We wish to thank Mr. W. Stockdale, Division o Physics, National Research Council, for carrying out

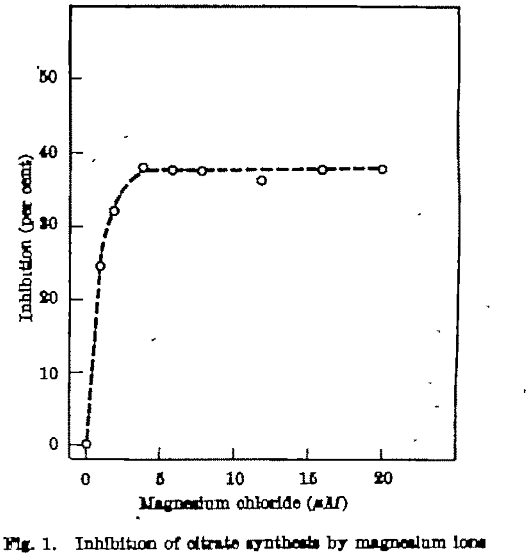

Fig. 1. Inhibition of citrate synthesis by magnesium ions

he spectrographic analyses, and to acknowledge the technical assistance of Mr. J. T. Slobodian.

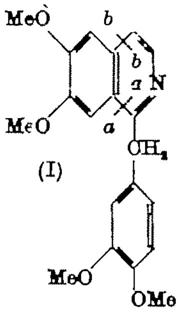
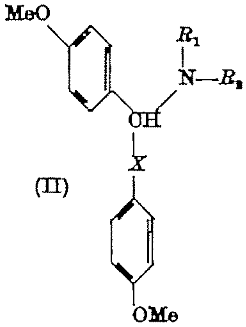
New Synthetic Antispasmodics

A recent publication[1] prompts us to report the preparation of a number of novel synthetic antispasmodics related to papaverine. The numerous synthetic analogues of papaverine (I) which have been prepared (see, for example, Blicke[2]) can be divided into two main groups: (1) those with an intact *iso*quinoline ring system (for example, eupaverine[3]) and (2) those in which the *iso*quinoline ring has been opened at the line *a*—*a* to give a *bis*-(2-phenylethyl)amine (for example, sestron[4]).



(I)



(II)

A third type of papaverine analogue, obtained by opening the *iso*quinoline ring along the line *b*—*b*, does not seem to have been investigated (except that α-diethylamino-4-methoxy deoxybenzoin is reported[5] to have half the antispasmodic activity of papaverine in an isolated observation), and we now report the synthesis and activities of a series of compounds of that type.

A series of N-alkyl-1 : 2-di-(*p*-methoxyphenyl)-ethylamines (II; $X = CH_2$), N-alkyl-α-aminodeoxyanisoins (II; $X = CO$), and N-alkyl-2-amino-1 : 2-di(*p*-methoxyphenyl) ethanols (II; $X = CHOH$) were prepared and, in view of the promising activity of certain 1-phenyl *iso*quinoline compounds, in which the methylene bridge was omitted (for example, neupaverine[3]), a number of N-alkyl-di-(*p*-methoxyphenyl)-methylamines (II; $X = —$) were also synthesized for this work.

Tested on isolated guinea pig ileum against spasms produced by barium chloride and carbachol, using papaverine and atropine as standards, all compounds exhibited spasmolytic activity. In order to obtain a valid comparison, the relative potencies are quoted on a molar basis (see Table 1).

Table 1 Spasmolytic Activities

Compound II			Relative potency (molar)	Compound II			Relative potency (molar)
X	R_1	R_2		*X*	R_1	R_2	
CO	H	Me	0·9	CH_2	H	H	0·8
CO	H	Et	1·2	CH_2	H	Et	0·9
CO	H	*iso*Pr	0·8	CH_2	H	*iso*Pr	1·2
CO	Me	Me	2·5*				
CO	Et	Et	0·2*				
CHOH	H	Me	0·8	—	H	H	0·8
CHOH	H	Et	0·8	—	H	Me	1·8
CHOH	H	*iso*Pr	0·5	—	H	Et	0·8
CHOH	Me	Me	0·2*	—	Me	Me	1·1
CHOH	Et	Et	1·2*	—	Et	Et	1·0
Papaverine			1·0	—	H	*iso*Pr	0·6

* With these compounds spasm of the guinea pig ileum was induced with posterior pituitary extract.

Relative neurotropic activity was between 0·005 and 0·2 of atropine, and acute toxicities (intravenous in mice) were uniformly between 60 and 80 mgm./kgm. for all series; that is, with an LD_{50} of two to three times that of papaverine ($LD_{50} = 30$ mgm./kgm.). In view of these promising results, these and other related compounds are undergoing further investigation, and details will be reported in full elsewhere.

We are indebted to the National Health and Medical Research Council for financial support.

Efficiency of Oxidative Phosphorylation

The quantitative yield of phosphate fixed during cellular oxidations deserves critical investigation, for it determines the efficiency with which utilizable energy may be derived from assimilated foodstuffs and it may influence metabolic regulatory mechanisms[1]. This problem has been the subject of many investigations (cf. Krebs *et al.*[2] and Slater and Holton[3]). In general, the observed yield has increased over a period of years as newer methods of measurement have been developed and particularly as more knowledge has been made available concerning the preparation of undamaged mitochondria which are free from interfering cellular components.

For example, Ochoa[4], in 1944, observed a phosphorus/oxygen ratio of 1·4–1·7 for the single-step oxidation of α-ketoglutarate to succinate by a dialysed extract of cat heart. By correcting for previously measured losses of high-energy phosphate occurring in the system, a value of 3 for the actual ratio was deduced. In more recent investigations with mitochondria prepared from liver heart muscle by the procedure of Schneider[5], the same oxidative reaction proceeds with measured phosphorus/oxygen ratios greater than 3 [3,6,7].

Slater, Cleland and Holton, in an extensive study of heart sarcosomes[3,8], have consistently obtained phosphorus/oxygen ratios lower than 3 for α-ketoglutarate oxidation and have concluded[3] that values greater than 3 are in error. The over-estimation of phosphorylating efficiency is ascribed to an underestimation of oxygen consumption in the case of the work by Copenhaver and Lardy, and to a possible inherent error in the assumption by Krebs *et al.*[2] that rates of incorporation of $H^{32}PO_4^{2-}$ into adenosine triphosphate can be used to calculate phosphorus/oxygen ratios. Arguments supporting these contentions were presented *in extenso* by Slater and Holton[3] and those pertaining to our paper will be answered briefly here.

Stoichiometry of the reaction. Slater and Holton[3] find heart sarcosomes, in the presence of 0·01 *M* malonate, oxidize α-ketoglutarate beyond the stage of succinate (O/α-kg = 0·95–1·28; mean 1·13); Copenhaver and Lardy, in twenty experiments, obtained values of 0·8 to 1·1; mean, 0·975. From the low inhibition index of malonate vs. succinate, one would predict that 0·01 *M* malonate is sufficient to block succinate oxidation virtually completely. This was put to test using the experimental conditions described[6], and it was found that 5 μmoles of succinate (the average amount formed during the 15–25 min. experimental period) supported no discernible oxygen consumption above that in control flasks without added substrate. The respiration in the latter case was either zero or so low as to be an insignificant portion of that occurring in the presence of substrate. (Experiments have also shown that the hexokinase preparation used[6,9,11] does not fix inorganic phosphate in the absence of mitochondria.)

Measurement of oxygen consumption. Slater and Holton[3] consider a 5-min. equilibration period insufficient to bring the flask contents to equilibrium in the 30° Warburg bath. They cite an experiment attempting to duplicate the technique employed in this laboratory. They report that with their equipment a period of 22 min. was required to reach thermal equilibrium, that a lag in oxygen consumption occurred during the first 5 min. of measuring respiration, and that a phosphorus/oxygen ratio of 4·55 is obtained. Under our conditions (thin-walled flasks of 16 ml. volume, 3·0 ml. fluid, bath covering flasks above ground joint, shaking at 120 excursions/min. and stopcocks closed during last minute of equilibration period) thermal equilibrium is reached in 5 min. (± 2 mm. of Brodie's fluid). The complete absence of a lag period in oxygen consumption in our phosphorylation experiments is shown in eleven charts in the paper[6] accompanying that criticized by Slater and Holton.

Stability of mitochrondrial system. Slater and Holton[3] consider metal chelating agents such as ethylenediaminetetraacetic acid to be essential to stabilize the enzyme system of sarcosomes. It is possible that the higher level of adenosine triphosphate employed in our experiments (0·002 *M*) accomplishes the same result, for respiration is a linear function of time for periods of at least an hour when an adequate supply of inorganic phosphate and phosphate acceptor is present[9]. Under these conditions (Fig. 4, ref. 9) the measured phosphorus/oxygen ratios for α-ketoglutarate oxidation in the absence of agents which block the Krebs cycle is 2·8 at a 20-min. and 2·56 for a 70-min. experimental period. Slater and Holton (Table V, ref. 3) find a ratio of 1·71 for a similar unblocked system with rat heart sarcosomes prepared in saline-ethylenediaminetetraacetic acid. From this it is clear that the liver mitochondria prepared in sucrose were fixing more phosphate per unit of oxyge consumed than were the sarcosomes. As has bee pointed out[3], these differences are not inherent i the two tissues, for Maley and Plaut[7] find phosphoru oxygen ratios greater than 3 for α-ketoglutara oxidation by heart mitochondria and Slater an Holton[3] find 2·5 for liver mitochondria.

A most critical test of the degree to which oxidatio is 'coupled' with phosphorylation involves th measurement of respiration in the presence an absence of a phosphate acceptor system[10,11]. Th respiration of fresh mitochondria is enhanced som four- to fifteen-fold by the addition of a phosphat acceptor or by agents such as 2,4-dinitrophenol[1,1 and, in general, systems which do not exhibit thi effect have a lowered phosphorylation efficiency. I is felt that this test should be applied routinel when there is any doubt about the phosphorylatin efficiency of mitochondrial preparations.

Phosphorylating efficiency during oxidation of β hydroxybutyrate. It is generally agreed that th oxidation of α-ketoglutarate to succinate support one more phosphorylation than does the oxidatio of β-hydroxybutyrate to acetoacetate. Quantitativ studies of the latter oxidation with mitochondri have yielded phosphorus/oxygen ratios between 2· and 3 [4,5,11]. Ratios as great as 2·5 have been measure after 180 min. equilibration[11].

These results support the view that the phosphoru oxygen ratio for oxidation of β-hydroxybutyrat approaches 3, while that for oxidation of α-ketc glutarate to succinate approaches a value of 4.

Chemical Form of Phosphorus-32 produced in Aluminium by Bombardment with Nitrogen

MULTIPLY-CHARGED ions of elements up to neo have recently been accelerated to energies of th order of 100 MeV. in the Nuffield Laboratory 60-in cyclotron at Birmingham[1]. Some of these ions hav been used in bombardment studies[2]. Among th radioactive products is phosphorus-32, which i formed, for example, in relatively large yield i bombardments of aluminium-27 with $^{14}N^{6+}$ ions. W have carried out experiments designed to show i what chemical state these atoms are held in the target

The results of the experiments indicate that o dissolving a bombarded aluminium foil in sodium ydroxide solution in the absence of air, about two-irds of the recovered activity is carried by gaseous hosphine and the remainder enters solution as a duced oxy-phosphorus ion, probably hypophosphite. he proportion forming phosphate ion is undetectable ithout the use of drastic oxidizing conditions. We ave shown that the reducing action of the aluminium dissolving, under our experimental conditions, is sufficient to convert more than a very small fraction previously dissolved hypophosphite to phosphine. his suggests, although it does not prove, that the dioactive phosphine is a true primary chemical action product.

The absence of phosphorus-32 in the form of hosphate ion indicates that the phosphorus-32 atoms, though undoubtedly initially formed with a high sitive charge, do not persist in that state. On the her hand, the presence of radioactive hypophosphite n shows that not all the phosphorus-32 atoms main in the lattice as phosphide ions, because if is were so one would expect to get all the activity phosphine. This suggests an intermediate valency ate.

It does not seem likely that oxygen atoms dventitiously present in the target can have affected e result. Whitmore showed that when phoshorus-32 is produced by fast-neutron irradiation of iourea or sodium sulphide, no activity appears as hosphine on treatment with air-free water; by far e larger part of the activity is found as one or ther of the oxyphosphorus acids[3]. However, no pecial precautions were taken to exclude oxygen gorously during the bombardment, and Koski has own that in the production of sulphur-35 by fast-eutron reactions in potassium chloride the rigorous pulsion of occluded air enables one to observe the lphur-35 atoms in a sulphide fraction rather than s sulphate[4]. The oxygen content of spectroscopically ure aluminium is, however, very low by ordinary andards except, of course, at the surface, and in ny event it is doubtful whether phosphorus atoms uld successfully compete for oxygen atoms with e aluminium.

As is well known, the reaction between ordinary lemental phosphorus and caustic alkali leads to the rmation of phosphine and hypophosphite ion in e molecular ratio 1 : 3. Our results would therere have been obtained if half the phosphorus-32 toms had reacted as phosphide and half as elemental hosphorus. An objection to this naive view is that ne could not fairly expect an isolated phosphorus tom embedded in a foreign lattice to undergo the me reactions as in its normal elemental environent. Furthermore, we find it hard to believe that e phosphorus-32 atoms are held in the aluminium non-equivalent states; for the lattice must be riously disturbed by the passage of the phoshorus-32 atoms (and other reaction products and ombarding particles) before coming to rest, the total nergy dissipated, in many experiments, being fficient to raise the temperature of the target early to the melting point. Consequently, all the hosphorus-32 atoms must have been able to find tes of minimum potential energy.

An explanation of the observations must therefore e sought in a consideration of the chemical species hich may be supposed to react with the phoshorus-32 atoms. These comprise not only water olecules, hydrogen ions and hydroxyl ions, but also ydrogen atoms produced by the reaction of neighouring aluminium atoms with the dissolving solution. On this basis we may postulate that the phosphorus-32 atoms are all present in a very low, or even zero, state of charge, and the reaction yields reflect competition between overall reactions such as:

$$P + 3H \rightarrow PH_3\,; \qquad P + 2H_2O \rightarrow H_3PO_2 + H$$

or

$$P^+ + 4H \rightarrow PH_3 + H^+\,; \qquad P^+ + 2H_2O \rightarrow H_3PO_2 + H^+.$$

It is clear that a great deal remains to be understood about this kind of problem, and we hope, when the cyclotron is in operation again after the current reconstruction is completed, to make a more detailed investigation. We should like to thank Prof. P. B. Moon and Dr. D. Walker, of this laboratory, and Dr. A. G. Maddock, of the University of Cambridge, for useful discussions.

Methods of Calculation of Polarographic Currents for Depolarization Schemes involving Reactions of Higher Order

IN the course of investigations concerning the mathematical analysis of rate-controlled polarographic limiting currents, rigorous methods have been worked out which make it possible to evaluate the rate constants of chemical reactions involved in the depolarization process, when the reactions are of the first order (for review, see ref. 1).

If the depolarization process at the dropping mercury electrode involves a reaction of the second or higher order, the depolarization current resulting from the flux of the depolarizer at the electrode surface can be calculated by solving the following general system of equations:

$$\frac{\partial a_i}{\partial t} = D_i \frac{\partial^2 a_i}{\partial x^2} + \frac{2x}{3t} \frac{\partial a_i}{\partial x} + F_i\,(a_1, \ldots a_n)\,; \quad i = 1, \ldots n. \tag{1}$$

$$x > 0,\ t = 0 : a_i = \alpha_i\,; \tag{2}$$

$$x = 0,\ t > 0 : D_i \frac{\partial a_i}{\partial x} = \sum_{j=1}^{n} m_{ij}\, a_j\,; \tag{3}$$

where the second term on the right-hand side of equation (1) accounts for the expansion of the electrode against the solution[2], x is the distance from the surface of the dropping electrode, t the time measured from the beginning of drop formation, a_i and D_i the concentration and diffusion coefficient of reactant A_i, respectively, and m_{ij} the rate constants of the electrode reactions referred to unit area; these depend on the electrode potential. Now whereas for monomolecular reactions the last term of equation (1) may be written in general

$$F_i\,(a_1, \ldots a_n) = \sum_{j=1}^{n} k_{ij}\, a_j, \qquad (4)$$

this does not hold for the case of reactions of a higher order.

In view of the difficulties involved in the solution of problems of this type, the treatment will be restricted here to cases where the chemical reactions involved in the depolarization scheme are either very slow (case *A*) or very fast (case *B*).

In both cases, we first try to find linear combinations of the type

$$\psi_k = \sum_{l=1}^{n} \varkappa_{kl}\, a_l \qquad (5)$$

which would satisfy equations of the type

$$\frac{\partial\psi_k}{\partial t} = \overline{D}_k\, \frac{\partial^2\psi_k}{\partial x^2} + \frac{2x}{3t}\, \frac{\partial\psi_k}{\partial x}. \qquad (6)$$

In case *A*, equations (6) as well as the equations for the remaining concentrations a_l are transformed by introducing the independent variables s_i and η[3,4]:

$$s_i = \frac{x}{\sqrt{\frac{12}{7}\, D_i t}}, \quad \eta = Ct. \qquad (7)$$

The solution is taken to be of the form

$$a_i = \sum_{j=1}^{\infty} \varphi_j^{(i)}(s_i)\, \eta^j, \qquad (8)$$

where the functions $\varphi_j^{(i)}$ satisfy the equations:

$$\varphi_j^{(i)''} + 2s_i\, \varphi_j^{(i)'} - \frac{12}{7}\, j\varphi_j^{(i)} = g_j\,[\varphi_0^{(1)}, \ldots \varphi_{j-1}^{(1)}; \ldots; \varphi_0^{(n)}, \ldots \varphi_{j-1}^{(n)}]. \qquad (9)$$

Here g_j can be regarded as known functions of s_i. Since the solution of equation (9) with the right-hand side equal to zero is known[1-4], the solution of the complete equations (9) presents no further difficulty. The integration constants appearing in this solution can be determined from the boundary and initial conditions (2) and (3), respectively. The mean value of the polarographic depolarization current is then calculated in the usual manner[3,4]. The successful evaluation of the specific rate of dismutation of pentavalent uranium from the limiting currents of the uranyl ion represents a special case of this general treatment[5,6].

Considering case *B*, it is often possible to write the differential equations (1), left after the transformation (5) in an approximate form (cf. refs. 3, 4),

$$D_i\, \frac{d^2 a_i}{dx^2} - \phi_i\,(a_i\,;\; \psi_1, \ldots \psi_m) = 0, \qquad (10)$$

where $\psi_1 \ldots \psi_m$ are defined by equations (5). For small values of x, the functions ψ can be regarded as independent of x, so that:

$$D_i\left(\frac{da_i}{dx}\right)^2 = 2\!\int\!\phi_i\,(a_i;\; \psi_1, \ldots \psi_m)\, da_i + K. \qquad (11)$$

Since equilibrium of the chemical reaction is established at distances from the electrode which are negligible compared with the thickness of the diffusion layer, the value of the constant K in equation (11) can be determined. Equation (11), which represents the relationship between $\partial a_i/\partial x$ and a_i, makes it possible to eliminate the functions a_i from the mathematical formulation of the problem, just as in the treatment of very fast monomolecular reactions, and thus to reduce this problem to a simpler one, which is non-linear merely in the boundary conditions. It can be easily solved by means of the transformation (assuming the form[3,4]:

$$\psi_j = \sum_{k=0}^{\infty} \gamma_k^{(j)}\,[K_{jk}\,(s_j) - p_{jk}\, L_{jk}\,(s_j)\,]\eta^{k/2} + \frac{2}{\sqrt{\pi}}\, \psi_j^{(0)}\, L_0\,(s_j), \qquad (1$$

where

$$\psi_j^{(0)} = \sum_{l=1}^{n} \varkappa_{jl}\, a_l. \qquad (1$$

For the coefficients $\gamma_k^{(j)}$ recurrent relations a obtained by substituting (12) into the bounda conditions (3). The latter method has recently be applied in mathematical analysis of polarograph limiting currents due to the electro-reduction formaldehyde in unbuffered solutions. Under the conditions the hydroxyl ions, produced in the electro-process, catalyse the establishment of the equilibriu between the hydrated, polarographically inactiv and non-hydrated active forms of formaldehyd the former being always in a large excess over t latter[7].

Oxygen-18 Abundance in Fresh Water

MASS spectrometric tests of the oxygen-18 abundance, a_f, in a hundred and nine freshwater sampl obtained from various parts of the world, ha shown very considerable variations. When t samples are compared in relation to the climat conditions of the area of collection, the results indica a much decreased oxygen-18 abundance as t climate becomes colder. The deviations from a s standard ranged between + 32 × 10^{-4} and − 17 10^{-4} atom per cent.

This is due, principally, to the fact that ocean-wat vapour travelling towards colder regions yields pr cipitation the oxygen-18 abundance, a_p, of which, (account of the comparatively low vapour pressu of $H_2{}^{18}O$, is higher than the oxygen-18 abundanc a_v, of the vapour. In the remaining vapour, a_v a a_p in consequence gradually decrease. This fa has been confirmed experimentally by measur ments on precipitation from warm fronts. The measurements are in agreement with the followi formula, computed for variations in a_p with t temperature, T° K., of the condensed vapour:

$$\Delta(\log a_p) = \Delta(c_1 + \log(c_2 + c_3 T) + c_4 \log T + \left(c_5 T - \frac{c_6}{T}\right) \times 0{\cdot}43429$$

the c's being constants depending on a_v at the b ginning of the condensation, the evaporation tem rature of the water, and the vapour pressures, p and ^{18}p, of $H_2{}^{16}O$ and $H_2{}^{18}O$.

Conversely, evaporation will cause a rise in the xygen-18 abundance, a_f, in the remaining water.

By repeated circulatory processes, consisting of ying up on account of $\Delta T°$ cooling, warming up d renewed saturation, fractionation takes place, hereby the oxygen-18 abundance of the vapour, a_v, nverges towards a value where the deviation from e oxygen-18 abundance in the added vapour nstitutes :

$$1{\cdot}22 \times 10^{-4} \times \Delta T \frac{f}{1-f} \text{ atom per cent,}$$

here f is the ratio of the absolute humidity of the tmosphere at the beginning and at the termination f the condensation.

Since

$$a_p \cong a_v \frac{^{16}p}{^{18}p}\,,$$

e value of a_p for a certain precipitation depends on : 1) the nature of the circulatory processes earlier assed through by the atmosphere, namely, evaporation temperature, magnitude of earlier precipitations f water, and condensation temperature ; (2) evapration during precipitation from the cloud to the round ; and (3) origin of the vapour.

Point (3) implies that vapour from freshwater ontinental vapour) is considerably lighter than ocean vapour. Thus, 106 measurements of oxygen-18 bundance in vapour, a_v, from the Copenhagen area, aken over a period extending from about April 1953 o April 1954, showed that there was a distinct correlaion between a_v and deviations of the wind from the asterly direction. There were, moreover, appreciable easonal changes in a_v in the course of the year. he deviations from a set standard varied between + 10·3 × 10^{-4} atom per cent in July and − 5·8 × 0^{-4} atom per cent in February, corresponding to a ore intensive cooling off in the winter season.

For a certain locality, the oxygen-18 abundance, $_f$, of freshwater also depends on : (4) the proportions f water lost by drainage and by evaporation from he ground ; (5) the exchange of oxygen-18 between he ground water and substances in the ground ontaining oxygen.

Measurements of sixty-one samples of precipitation howed comparatively large variations in a_p (ranging rom + 9 × 10^{-4} to + 31 × 10^{-4} atom per cent) ; owever, the mean value (+ 22 × 10^{-4} atom per ent) was in agreement with that of a_f for the ground vater ; consequently, points (4) and (5) can scarcely e of any significance in the conditions prevailing in enmark.

Since the significance of point (3) for the oxygen-18 bundance, a_p, of the average precipitation can be etermined from climatological data, while point (2) s of no significance in violent and/or persistent recipitation, it is possible by measurements on the recipitation, the vapour and the ground water nd by noting the climatological and the geographical onditions, to arrive at a quantitative interpretation f oxygen-18 abundance for freshwater, a_f, at a iven locality.

Odour and Chemical Constitution

In a discussion of this problem, Dr. G. Malcolm Dyson (*Nature* of May 1, p. 831) refers to "the 'camphor-like' groups in which such diverse substances as camphor, hexachloroethane, benzene hexachloride and perchloronaphthalene have closely related odours".

Many years ago (*J. Chim. Phys.*, 35, 331 (1938), and also 3e Congrès National des Sciences, Bruxelles; 1950) and in my recent book, "Les Constantes Physiques des Composés Organiques Cristallisés" (Masson and Co., Paris, 1953, pp. 49–51 and p. 500), I have pointed out that most such substances belong to a natural group of organic compounds, defined by their low entropy of melting (< 5). As their molecules have a spherical shape, I proposed for them the name of 'globular compounds'; they possess many other common properties, although as different in their chemical constitution as natural camphor, α-hexachlorbenzene and artificial camphor, $CCl_3.C(CH_3)_2.OH$.

So far as I know, most compounds smelling like camphor have that configuration (methyl*cyclo*pentanol has not), but all globular compounds do not smell like camphor.

I have directed the attention of physiologists to this curious relation between the olfactory properties and the stereochemical configuration of such compounds, a relationship which is quite different from the study of small changes in the chemical constitution of organic compounds and their physiological action, as has hitherto been made.

Caution in the Use of Liquid Propane for freezing Biological Specimens

One of the recent innovations in freezing and drying technique is the use of liquid propane for rapid freezing. This material has explosive possibilities when cooled in liquid nitrogen that many investigators do not seem to realize. Liquid nitrogen boils at − 195·8° C., liquid oxygen at − 183·0° C. It is common experience that if a vapour trap is cooled with liquid nitrogen and open to the atmosphere, oxygen will condense in it. Since propane melts at − 189·9° C., in the range of temperatures between its melting point and the boiling point of oxygen it is theoretically possible to get a mixture of liquid oxygen and liquid propane.

On one occasion when I was slowly condensing propane in a flask chilled with liquid nitrogen, I obtained what appeared to be such a mixture : that is, I obtained two distinct layers of liquid in the flask, one of which had the characteristic appearance of liquid oxygen.

This experience suggested two precautions to be observed when working with liquid propane : (1) when condensing the material, to keep a sufficiently rapid flow into the condensing flask to exclude air ; (2) keep the material at all times above the boiling point of oxygen, say, above − 180° C. Of course, similar precautions should be observed with other combustible materials the melting point of which is below the boiling point of oxygen.

APPOINTMENTS VACANT

Applications are invited for the following appointments on or before the dates mentioned:

Scientific Officer (honours graduate, preferably with postgraduate experience in genetics), at the Plant Breeding Station—The Secretary, National Vegetable Research Station, Wellesbourne, Warwick (August 4).

Assistant (with a degree in agriculture or pure science, with special qualifications in botany or crop husbandry) in Agriculture—The Secretary, The University, Aberdeen (August 7).

General Assistant Engineer (with a degree in electrical or mechanical engineering or in physics), at the British Electricity Authorities Research Laboratories, Leatherhead for duties which include testing, development and research work in the laboratories; and in the field in connexion with the generation, transmission and distribution of electricity—D. Moffat, Director of Establishments, British Electricity Authority, Winsley Street, London, W.1, quoting N/481 (August 7).

Lecturer (university graduate in physics, with teaching and/or industrial experience) in Physics, to teach to B.Sc. general degree standard—The Principal, Enfield Technical College, Queensway, Enfield, Middlesex (August 7).

Principal Scientific Officer (with a first- or second-class honours degree in engineering, or equivalent, and preferably with a knowledge of French and/or German and experience of committee work) in the Mechanical Engineering Research Laboratory (Materials Division), East Kilbride, Glasgow, to lead a team determining the mechanical properties of materials, studying fatigue, and examining machine parts which have failed in service—The Civil Service Commission, Scientific Branch, 30 Old Burlington Street, London, W.1, quoting S4356/54 (August 12).

Physics Lecturer (with a first- or second-class honours degree, and preferably with experience in the nuclear reactor field at the appropriate level, and teaching ability) to take charge of the Physics Course in the Reactor School—The Establishment Officer, Atomic Energy Research Establishment, Harwell Berkshire, quoting 2/103/119 (August 13).

Assistant Lecturer in the Department of Geography and Anthropology—The Registrar, University College of Wales, Aberystwyth (August 14).

Assistant Lecturer in Zoology, and a Research Demonstrator in Zoology—The Registrar, The University, Reading (August 14).

Physicist (Ph.D. standard, and prepared to spend a considerable time abroad), to collaborate with geologists in the collection and preparation of rock samples and in the measurement of their magnetic properties over a wide area—Prof. Blackett, Physics Department, Imperial College of Science and Technology, London, S.W.7 (August 14).

Senior Physicist (with some knowledge of the chemical and biochemical procedures associated with the clinical applications of radioactive isotopes), to be responsible, under the direction of the Regional Physicist, for providing technical advice and assistance to clinical research teams using radioactive isotopes—The Administrative Officer, Board of Management for Glasgow Western Hospitals, Regional Physics Department, 9–13 West Graham Street, Glasgow, C.4 (August 14).

Lecturer (with a special interest in the strength of materials) in the Department of Mechanical Engineering—The Registrar, The University, Liverpool (August 21)

Lecturer in Applied Mathematics at the University of Cape Town, South Africa—The Secretary, Association of Universities of the British Commonwealth, 5 Gordon Square, London, W.C.1 (August 27).

Lecturer and an Assistant Lecturer in the Department of Physics—The Registrar, The University, Manchester 13 (August 28).

Lecturer or Assistant Lecturer in the Department of Mathematics at the University College of the West Indies—The Secretary, Inter-University Council for Higher Education in the Colonies, 1 Gordon Square, London, W.C.1 (August 30).

Chemist (with a specialized interest in analytical techniques), for a permanent academic appointment with the status of Fellow or Senior Fellow, responsible for the Analytical Section of the Department of Radiochemistry, Research School of Physical Sciences, Australian National University—The Secretary, Association of Universities of the British Commonwealth, 5 Gordon Square, London, W.C.1 (August 31).

Lecturer (with qualifications in cultural (including economic) geography, and ability to conduct postgraduate courses in economic, historical or colonial geography) in Geography; and a Lecturer in Chemistry, at Auckland University College, New Zealand—The Secretary, Association of Universities of the British Commonwealth, 5 Gordon Square, London, W.C.1 (New Zealand, August 31).

Senior Lecturer in Chemistry at Canterbury University College, Christchurch, New Zealand—The Secretary, Association of Universities of the British Commonwealth, 5 Gordon Square, London, W.C.1 (New Zealand, August 31).

Senior Lecturer (with an honours degree or preferably a higher degree and, in addition, teaching and/or industrial experience in metallurgy) in Metallurgy, at the University of the Witwatersrand, Johannesburg, South Africa—The Secretary, Association of Universities of the British Commonwealth, 5 Gordon Square, London, W.C.1 (South Africa, August 31).

Senior Research Fellow (with experience in wind-tunnel work) in the Department of Aeronautical Engineering, to design new high-speed laboratory equipment, and to take a leading part in research work—The Secretary and Registrar, The University, Southampton (August 31).

Scientific Officer (with a good honours degree in chemistry, biochemistry or botany, and a sound knowledge of organic chemistry and keen interest in the living plant) in the Biochemistry Section, for research on the biochemistry and metabolism of the fruit tree—The Secretary, East Malling Research Station, near Maidstone, Kent (September 7).

Assistant Lecturer (with an interest in histology) in Anatomy—The Registrar, University College of South Wales and Monmouthshire, Cathays Park, Cardiff (September 11).

Lecturer or Assistant Lecturer in Geography at Makere College, University College of East Africa—The Secretary, Inte University Council for Higher Education in the Colonies, 1 Gord Square, London, W.C.1 (September 30).

Scholars (with a M.Sc. degree or equivalent research experienc in the Departments of Biochemistry, Microbiology and Physiology, John Curtin School of Medical Research, Australian Nation University—The Secretary, Association of Universities of the Brit Commonwealth, 5 Gordon Square, London, W.C.1 (September 30).

Chair of Agriculture, Chair of Physics, Chair of Chemistr Chair of Botany and Chair of Zoology at Rhodesia Universit College, Salisbury—The Secretary, Inter-University Council for High Education in the Colonies, 1 Gordon Square, London, W.C. (October 18).

Assistant Lecturer (with a degree in physics or equivale qualifications, and preferably with industrial experience) in Natura Philosophy—The Secretary, Royal Technical College, Glasgow.

Chemical Engineer (with a first- or second-class honours degre in chemical engineering or equivalent, with considerable postgraduat experience in development work, including the design of pilot plant at a Ministry of Supply Establishment in S.W England, for wor concerned with the development of technical processes involving semi technical research, and the design and operation of pilot units—Th Ministry of Labour and National Service, Technical and Scientif Register (K), 26 King Street, London, S.W.1, quoting F501/54A

Demonstrator in Physics—The Registrar, The Universit Nottingham.

Geologist (with an honours degree in geology) with the Falkland Island Dependencies Survey, for service at Hope Bay in the Antarct —The Crown Agents for the Colonies, 4 Millbank, London, S.W.1 quoting M3B/34380/TA.

Head of the Department of Organic Chemistry—The Academ Secretary, Weizmann Institute of Science, Rehovoth, Israel.

Lecturer (graduate, and able to teach agricultural botany an zoology, including entomology, to diploma standard) in Agricultura Botany—The Principal, Shuttleworth College, Old Warden Park Nr. Biggleswade.

Meteorological Assistants (male or female) (with considerabl experience in routine meteorological office work, especially the makin of observations and the plotting of maps); and a Senior Meteorological Assistant (male) (able to maintain meteorological instruments and prepare climatological records), with the Bermuda Government—The Crown Agents for the Colonies, 4 Millbank, London, S.W.1 quoting M3B/34501/NF.

Senior Lecturer in Chemical Engineering, to plan new course and laboratories—The Principal, Royal Technical College, Salford.

Senior Scientific Officer (with a first- or second-class honour degree in chemistry, or equivalent qualifications, and at least thre years postgraduate experience including supervision of staff in researc laboratories), to be responsible for advising technical and professiona staff on safety matters in relation to laboratories, pilot plants, an production techniques, in a wide range of chemical and physica research problems—The Administrative Officer (Recruitment), Atomi Weapons Research Establishment, Aldermaston, Berkshire, quotin 132/WGH/2.

Soils Research Officer (with a first- or second-class honour degree in an appropriate scientific subject, and experience in the techniques of physical and chemical analysis of soils and the interpretatio of the results obtained), at the Alice Holt, Surrey, branch of the Forestry Commission, to carry out soil studies in connexion wit ecological, silvicultural and pathological problems in British forestry—The Ministry of Labour and National Service, Technical and Scientifi Register (K), 26 King Street, London, S.W.1, quoting G254/54A.

Statistician (with suitable qualifications, and preferably experienc at field trials)—The Secretary, National Institute of Agricultural Botany, Huntingdon Road, Cambridge

KNOWLEDGE AND RESPONSIBILITY

THE anxiety and alarm which were aroused in the general community by the first reports of the effects of the explosion of the hydrogen bomb in the Marshall Islands on March 1, particularly on account of the contamination reported to have occurred outside the supposed danger-zone and of errors in meteorological prediction and miscalculations of the violence of the explosions, have now somewhat subsided. The Prime Minister, following the reassuring comments made by Prof. M. L. Oliphant and Prof. O. R. Frisch, has refuted the idea that the scientists were unable to set limits to the explosive power of the bombs they were testing. In that sense the explosions were not 'incalculable' and the limits of the danger, though wide, are clearly set.

Nevertheless, in spite of such clear explanatory articles as that of Prof. Frisch in the *Atomic Scientists Journal*, and Mr. Strauss's statement on the tests on March 31, the question has been raised in responsible quarters as to whether it is wise to proceed with such tests. The question was first raised in the belief that it was possible that the consequences of such explosions could no longer be predicted, and the suggestion implied that the decision to discontinue such tests was one for scientists themselves to take. It has further been questioned whether such tests are not merely unwise from a scientific point of view but also even strategically necessary. It has been suggested that atomic weapons may provide adequate deterrents just as effective as the hydrogen bomb and possibly more economical.

Such suggestions have tended to encourage a popular belief that the scientist carries a much larger share of responsibility than can fairly be attributed to him, and this view is also fostered by the way in which the general issue of the scientist's power over Nature is presented, for example, in Mr. Charles Morgan's "The Burning Glass" (Macmillan and Co., Ltd., 9*s*. 6*d*.). There have always been people who are ready to call a halt to scientific and technological advance. When Mr. Morgan writes in the introductory essay to his play, "History moves in phases; the power-phase may be drawing to its close; there may be a halt for many centuries in all but the minor developments of technology", he is expressing a hope which is evidently shared by many men and women and also by the central character of his play—Christopher Terriford—whom he describes as "not the only man of science with the wisdom to desire it".

Much to be found in Dr. Lewis Mumford's writings outstrips the imagination of power as a self-vindicating end; but this is not to accept the thesis that the scientist should abandon his quest for formidable sources of power, or at least should not disclose them to his fellow-men. To do so is in fact to accept a responsibility which belongs to the community and not to any one section of it, and the great value of this essay of Mr. Morgan's is that, dealing with power over Nature in general terms, it throws a good deal of light on the real issues involved in the use of the scientist or technologist in the service of the State.

The central theme of the play is the right of the scientist to withhold knowledge and whether there are not inexorable limits to the mind of man. Mr. Morgan believes that there are such limits, and that we should deliberately limit our powers over Nature, because the development of that power has reached a stage which implies a subversion of the natural order. In the belief that this subversion is devilish and that the limitation of power is the only way of restoring balance and sanity to life, Mr. Morgan portrays a scientist in whom the tradition of scientific research, with its presupposed community of knowledge to which his results are freely contributed, is in conflict with his impulse to conceal a discovery on which he has stumbled by one of those intuitive and inexplicable leaps of mind of the creative worker, because of its devastating consequences if put to military use.

In his introductory essay, "Power over Nature", Mr. Morgan discusses this conflict in Christopher Terriford's mind and some—but not all—of its implications for the world in the context of atomic power. The dilemma as portrayed here is one with which flashes of intuition might confront the creative worker in many fields of knowledge; but what comes out only imperfectly in the play is that the dilemma is false. The choice to withhold or communicate knowledge, and also the decision as to what action should be taken on it, is not one for the scientist as such. It is one for the community which has set him to work, and ultimately, in a democratic community, for the government which that community has put into power.

Nearly five generations ago, Tredgold defined the profession of civil engineer as "the art of directing the great sources of power in Nature for the use and convenience of man". We might, to-day, fairly speak of science, though Tredgold used the word 'art' in the sense in which it is used in the title of the Royal Society of Arts, implying the use of imagination and experience as well as technique. Mr. Morgan can fittingly write of power over Nature; but Tredgold's definition still gives the better clue to the heart of the problem. The task of the scientist or technologist is to place at the service of the community the resources it needs, and to show how best they can be used. He has the responsibility of warning the community of the dangers that may attend the misuse of such knowledge and the failure to use it with due safeguards. The decision whether or not to use that knowledge in a particular way or for a specific purpose is one which he shares with the community as a whole.

In that sense, accordingly, the problem for the scientist or technologist is one not of power but of influence. His responsibility is not for the use made of the knowledge he places at the disposal of society, but to see that his influence is most effectively exercised—to see that the consequences of using or abusing that knowledge are clearly and fully understood. Divesting himself of the power he is so often in error supposed to possess, he has to see that hi fellow-citizens appreciate the implications of the pow at their disposal, and to help them to make the inte lectual effort required for its control and wise use.

The hydrogen bomb, in fact, involves no fres responsibility for the scientist as such, least of a any new moral dilemma; and once these false ide are cleared out of the mind of the scientist himse and of the society in which he lives, there will b the less risk either of an anti-scientific attitude o the part of the public or of the scientist bein charged with a responsibility which he only shar with the whole community. As the Archbishop York said to the British Association at Liverpool, me of science "have an influence over contemporar thought and action which is possessed by no othe class of men. . . . They must educate their fellow countrymen to use rightly the inventions they hav given them, and must make plain the terrifying result which may follow their wrong use".

Beyond that the scientist has no right to go. H is not entitled, on his own responsibility, to withhol knowledge from the community he serves any mo than, as Dr. J. Bronowski pointed out in a recen broadcast, he is entitled to dictate to the natio about his own discoveries. He must be content t use his influence to guide his fellow-citizens to wis decisions; but he cannot impose these decisions. I return he can ask, in a free society, that he sha himself be free to follow his own conscience and tha society shall not dictate his life to him. He is entitle to urge on society the conditions in which effectiv scientific work is possible and to direct attention t the consequences which may attend restraints on th freedom of scientific investigation and intercours

The real challenge of the hydrogen bomb to th scientist is to consider even more carefully how be scientific thought can be put at the service of th community. If the community is to make th intellectual effort required in the shaping of it institutions to meet the requirements of an age i which technological advance has made so many its political divisions irrational and obsolete, the ma of science has a large part to play. He has to face i the first place the problem of the effective communica tion of knowledge and ideas, so that the leaders of th community can reach sound decisions based on clea appreciation of all the relevant factors, and so tha the community is prepared to accept whatever de mands these decisions may involve. This mean much more than questions of the presentation of hi own ideas and findings. It involves questions education and of public understanding, so that th issue is seen not as one of science letting natural force get out of hand, but of man's self-control and hi use of forces able to destroy him and his works.

For the scientist to take his place in that worl freedom of communication is vital. The scientis who has worked on guided missiles or atomic weapon is, as Dr. Bronowski rightly reminded us, seldom fre to speak as he would like, and this silence is a los to the community. Security considerations ma reasonably prevent the public discussion of technica details; but once such restrictions operate beyon e narrowest of such limits, they do more than mpede the exchange of ideas and the advance of ience and technology: they endanger national curity itself. Once the scientist comes to be silent, experiment or inquire only along orthodox lines, ience itself will atrophy and at last fail the nation which it is thus pursued. Without freedom for ience, and by attempting to silence or intimidate riginal and creative minds, in the end we forfeit curity itself.

Here, too, the scientist has a duty to speak, and hat is required of him in this perplexed and anxious orld to-day is not that he should refrain from ursuing his investigations and from seeking to extend ie boundaries of knowledge, or that he should preoccupy himself with moral issues that are the reponsibility of the whole community of nations. His mmediate responsibility is rather with the way in hich he can most speedily and effectively clarify ublic thinking about the scientific and technical spects of the situation, and facilitate an undertanding of the far-reaching military, economic and olitical decisions which are now imperative. He will e conscious that what he has to say as a scientist epresents only one factor in a complex situation, nd that this has to be compared with, and adjusted o, information from other fields, and evaluated with , in the formulation of policy. But it is important hat the scientist and technologist should, through heir professional associations, address themselves to his question of improving the means by which the echnical or scientific expert makes his contribution o the formulation of policy and the task of government generally. The task of education to be underaken must include that of the leaders of the community as well as of the general public. Above all, he extent to which the influence of the scientist is rought to bear on the formation of policy or the e-shaping of institutions will depend on the willingness of the individual scientist to attempt the prosaic ask of improving the channels of communication. Much will depend upon the effectiveness and clarity ith which he presents and interprets his results and deas to the community, and the fidelity and courage ith which he and his professional institutions defend he freedom of science, not simply for the advancement of science itself but also as an essential element n the preservation of a free society.

LIFE OF THOMAS YOUNG

homas Young
Natural Philosopher 1773–1829. By the late Dr. Alexander Wood; Completed by Frank Oldham. With a Memoir of Alexander Wood by Prof. Charles . Raven. Pp. xx + 355 + 4 plates. (Cambridge: At he University Press, 1954.) 30*s*. net.

IF the subject of this book did not make it immediately attractive, the authors' names would be sufficient recommendation in themselves. The ate Alex Wood gathered material for it over more han forty years and completed ten chapters and otes on two more. It has been finished and seen through the press by Frank Oldham, whose monograph, "Thomas Young, F.R.S., Philosopher and Physician" (London: Edward Arnold and Co., 1933), has, until now, been the standard authority.

In assessing the life and work of Thomas Young, the modern reader is torn between conflicting aspects of the man. If he had been always right we could unreservedly admire the precocious youth who gulped all knowledge of natural philosophy and of classical, European and oriental languages with full Quaker diligence and lack of conceit. We should have unstinted admiration for his mature work as a founder of the wave theory of light and for his solution of the hieroglyphic riddles of the Rosetta Stone, for his explanation of the mechanism of the human eye and for his numerous learned writings on medicine, physics and philology.

On the other hand, had he been less successful, we might condemn him as a quarrelsome man, ponderous and obscure in speech and in writing. His wide range of apparently unrelated interests might cause us to regard him as a butterfly mind rather than as a universal genius, and in his chosen career of medicine he was a failure in spite of much favourable opportunity.

Like most men, however, Young was neither wholly right nor wholly wrong. He was sufficiently right for most of his work to have stood the test of time and to be recognized now as a brilliant series of key contributions to the many fields which he studied. Unfortunately, he was also sufficiently wrong, particularly in his personal relations with other men of science, so as to be caught in the vicious web of priority claims and counter-claims which formed such a seamy side to the development of science in his period. The new material collected by Dr. Wood and Mr. Oldham does much to clarify Young's position and place him in a more favourable light.

It is very fitting that this book, which occupied so much of the leisure of Alex Wood's last years, should contain a sympathetic and eloquent memoir of him by Canon C. E. Raven. It will be appreciated by all those Cambridge men who owe so much to his great personality and teachings, and by all those who have found pleasure and profit in his writings.

DEREK J. PRICE

SCINTILLATION COUNTERS

Luminescence and the Scintillation Counter
By Dr. S. C. Curran. Pp. x + 219. (London: Butterworths Scientific Publications, 1953.) 32*s*. 6*d*.

THE development of methods of scintillation counting has advanced at an almost prodigious pace since Kallmann's first paper became known to a larger public in 1947. Superior in many respects to the older particle detectors and immensely flexible, the scintillation counter has found a steadily growing range of applications, and to-day it is firmly established as an indispensable tool in medicine and industry as well as in physics. Dr. S. C. Curran—himself a pioneer in this field whose unpublished work antedates that of Kallmann—has now written a little volume in answer to the widespread need for a comprehensive guide to the subject.

Well illustrated throughout its twelve chapters by instructive diagrams, the book is centred around a description of the basic mechanisms operating in a scintillation counter: the interaction of radiations and particles with matter, the luminescence process, photoelectricity and secondary emission. From there it proceeds to more technical items, such as the performance of commercial photomultipliers, the properties of scintillating materials and the preparation of crystals. The last chapters contain a survey of representative applications, including the direct counting of particles with open multipliers, and a brief discussion of various problems concerning the associated electronic circuits. Future developments and still unexplored possibilities are hinted at in many instances.

The author was certainly confronted with a thorny task in trying to bring order and proportion into this multitude of different topics. He has not shirked the countless obstacles on his way, but sometimes has not quite succeeded in surmounting them; his choice of emphasis or perspective is often unconvincing, and the great compression of material has led to a high stylistic density which makes the book difficult to read. That the two chapters on luminescence should be the weakest part of the whole can scarcely invite criticism, for it seems well-nigh impossible to give an adequate survey of so intricate and controversial a subject in merely forty pages. But—to touch only a few points—there is no need to digress on the ray-tracing methods of electron optics if afterwards no example is discussed of actual electron trajectories in one of the more common multiplier types; it confuses a delicate issue if the statistical fluctuations in the height of scintillation pulses are treated in connexion with the signal-to-noise ratio pertinent to cinema and television work; and in the section on crystal-growing, the sulphides and tungstates, with their attractive properties, would have deserved more than a few scant remarks. The inquisitive reader could have been helped here or there by the inclusion of references to suitable review articles, but several of the most competent ones are not mentioned.

Despite these shortcomings, the book will be most welcome as an introductory guide to prospective users of the scintillation counter, and as a handy manual to many research workers, bringing together, as it does, for the first time all the multifarious aspects of an exceedingly complex device.

Ernst Breitenberger

MODERN PHYSICS FOR DEGREE STUDENTS

An Introduction to Thermodynamics, the Kinetic Theory of Gases, and Statistical Mechanics

By Prof. Francis Weston Sears. Second edition. (Principles of Physics Series.) Pp. x+374. (Cambridge, Mass.: Addison-Wesley Publishing Company, Inc., 1953.) 7.50 dollars.

THIS text-book, written by the professor of physics at the Massachusetts Institute of Technology, constitutes one of the volumes of the "Principles of Physics Series". It is so eminently readable, however, that it will appeal not only to the physics student but equally to the engineering student who wishes to extend his reading beyond the limits of most engineering texts on thermodynamics.

The book brings together, at degree level, the fundamental principles of thermodynamics, kinetic theory and statistical mechanics. The first half deals with classical thermodynamics. An introductory chapter is followed by a discussion of the equation o state and *p-v-T* surfaces of ideal and real gases. Th sections on the first and second laws of thermodynamics, and their consequences, are separated b a chapter on changes of phase, in which the forms o the *p-v-T* surfaces for real substances are presente in a number of excellent three-dimensional diagrams These are a particular feature of the book. In chapter on the combined first and second laws, th engineer will find a very lucid treatment of th difference between the ice point and the triple poin of water, but will not agree with the statement tha his steam tables are based on the former as th datum state point. A very brief chapter on som engineering applications of thermodynamics concludes this first section.

The second half of the book is devoted abou equally to sections on kinetic theory and statistica mechanics. In the first of these, the derivation of th equation of state of an ideal gas, and a brief discussio of the Clausius and van der Waals equations of state are followed by the determination of the Maxwel distribution function, and a chapter on the transpor phenomena of viscosity, thermal conductivity an diffusion.

The concluding section follows the historical orde in the presentation of statistical mechanics, dealin first with the application of the Maxwell–Boltzman statistics to gases, with a paragraph on the specifi heat capacity of solids, followed by a section on th elementary theory of a paramagnetic gas.

In the section on quantum statistics, the Bose-Einstein distribution function is derived, but is applie only to the two special cases of an ordinary gas and photon gas, to show that the former application lead again to the Maxwell–Boltzmann distribution function and the latter gives the Planck distribution of energ density of radiation with frequency. The Fermi–Dira statistics for an electron gas are then discussed, bu are applied quantitatively only to the conditions a absolute zero of temperature, with a statement of th results obtained at temperatures other than this. final chapter deals with the theory of fluctuations, an its applications to the scattering of light, to Brownia motion and to background noise in amplifiers.

The limitation of the application of statistica mechanics to the simpler cases results in an exceptionally readable introduction to a difficult subject in which the physical implications of the mathematica manipulations are always clearly brought out. A the end of each chapter is a selection of problems with the answers provided. The MKS system of units i used throughout. The book is well produced, an suffers only from a number of minor misprints.

AMERICAN SCIENCE WRITING

Scientific American Reader

Pp. xiv+626. (New York: Simon and Schuste 1953.) 6 dollars.

NOW in its 108th year, the journal *Scientifi American* was taken over five years ago by small group of science journalists who were committe to the belief that there is a growing interest in clea and exact reporting of contemporary scientific event Their skill, energy and enthusiasm has led to succes and to-day the journal has a circulation in excess o 125,000.

To extend their field of readers, the editors have elected some of the articles from their journal which are of particular interest and put them together n book form. These articles have been grouped into welve 'chapters' and include accounts of recent nvestigations in astronomy, geophysics, atomic physics, natural evolution, genetics, the nature of iruses, neuro-humoral activities, animal behaviour, he origin of man, neurology, cybernetics and the basis of sensation and perception.

In the main the quality of the book is remarkably high. The editors deserve tribute for the catholicity f their selection, while most of the writers have earned praise for their clarity of presentation. Since his book is intended to provide a survey of contemporary events in the world of science for the general reader, however, it is surprising to find no reference to recent developments in chemotherapy or electronics. General readers would also have welcomed reference to the latest discoveries in artificial fibres which are already doing so much to change the habits of Western man and woman. Even more remarkable is the complete omission of information bout those new combinations of metals which are enabling man to build aircraft and other machines which were but dreams some twenty years ago. (It s indeed surprising how so many writers of popular science seem to forget the science of metallurgy, with ts overwhelming impact on everyday life. Why?)

In an American book consisting of articles designed mainly for American readers, it is not unexpected that most of the reporting refers mainly to work done by American men of science. An opportunity for popularizing the international character of science may have been lost, however, by the glaring omissions f work being done in other continents. This is all the more peculiar, since many of the American writers f this book began their lives and studies in European and other countries.

Among the outstanding features of a well-written book is a lucid chapter on galaxies in flight by Prof. George Gamow; a good essay on the military nd political implications of the use of the hydrogen bomb by Prof. Hans Bethe; a splendid account of recent researches in geological science by Walter Bucher; and a remarkably clear exposition of the meaning of pain by Prof. W. K. Livingston. A description of experiments in perception by two psychologists is a good example of how science should not be presented to the general reader. The book contains some useful diagrams with valuable explanatory texts.

T. H. HAWKINS

CHEMISTRY OF HETEROCYCLIC COMPOUNDS

ondensed Pyridazine and Pyrazine Rings
(Cinnolines, Phthalazines, and Quinoxalines). By . C. E. Simpson; pp. xvi+394; 12.50 dollars.

Imidazole and Its Derivatives
Part 1. By Prof. Klaus Hofmann; pp. xviii+448; 3.50 dollars.

The Chemistry of Heterocyclic Compounds: a Series f Monographs. (New York: Interscience Publishers, Inc.; London: Interscience Publishers, Ltd., 1953.)

IT can scarcely be doubted that progress in heterocyclic chemistry has been hampered by the lack f a comprehensive literature. Defined problems invite and inspire solution; but knowledge, when dispersed or in disarray, conceals its own gaps. The Weissberger series of monographs supplies one means by which the need may be met, and the two volumes here reviewed are respectively the fifth and sixth members of that series. Although in different ways, these volumes commemorate the work of two English chemists: for Dr. J. C. E. Simpson's authoritative writing on the chemistry of cinnolines perpetuates the inspiration he brought to the subject before his untimely death; and Prof. K. Hofmann's book is most fittingly dedicated to F. L. Pyman.

The book by Dr. Simpson is in three sections which correspond to the three types of heterocycle named in the title and include chapters both on the reduced systems and on more highly condensed, polycyclic systems. Each chapter deals with a sub-group of related compounds and is complete with a critical account of preparative methods, general properties and reactions, and a tabulated description of individual compounds, all fully documented. The chemistry of cinnolines and phthalazines is exhaustively covered up to the year 1949. The section on quinoxalines, however, although the largest in the book, omits references which are prior to 1917: for these the reader is referred to the review in Meyer–Jacobson's "Lehrbuch". This omission does not detract from the intelligibility of the section. Indeed, the whole book is characterized by a lucid and fluent exposition which succeeds in revealing both the chemical interest of the compounds and the gaps in our knowledge concerning them.

The volume on imidazoles (glyoxalines) has two sections, of which the first (pp. 3–324) is the main text of the book and is devoted to a review of fundamental imidazole chemistry. This is an excellent piece of work. It begins with a résumé of the evidence leading to the current concept of imidazole as a prototropic, highly associated and aromatic structure. There follows, class by class, a critical discussion of synthetic methods and chemical reactions of imidazoles, imidazolines and their derivatives. This is continued for imidazolidines as far as 2-imidazolidones and the corresponding thiones and imides, but at this stage there is an abrupt, unheralded transition to an excellent and comprehensive account of benzimidazoles. Compounds such as hydantoins are thereby omitted and, however expedient this may be, one regrets the break in continuity and unity. It is presumably in accordance with the policy expressed in earlier monographs of the series that imidazole alkaloids are also omitted. These comments do not detract from the value of the material presented. The treatment is sufficiently detailed to reward even the specialist, and yet it maintains a highly readable quality that must commend it to all organic chemists. References are assembled at the end of each chapter, and some of them relate to work published in 1952. The second section is a catalogue—comprising names, melting points, melting points of some derivatives and literature references—of all compounds which fall within the same scope and are found in the literature during the period 1919–50. It is thus in its way a supplement to Beilstein's "Handbuch".

Both volumes are well produced, adequately illustrated by clear structural formulæ and helpfully equipped with subject indexes. In certain places the second volume would benefit, through a less-encumbered text, had superscript numerals been used for references as in the other volume. But this is a small point amid so much that is commendable and welcome.

JAMES D. LOUDON

THE LIBRARY OF THE ROYAL INSTITUTION, 1799–1954

By K. D. C. VERNON

Librarian, Royal Institution

THE Library of the Royal Institution is known to many mainly as the place where the audience at the Friday Evening Discourses gathers before the lecture to meet friends and to look at the exhibits of scientific and general interest. But the Library has a story of its own, which has not been told before in consecutive form.

The first mention of the Institution's Library occurs in the Managers' minutes of April 20, 1799, about six weeks after the original meeting at which the Institution was formed, when it was reported that Sir John Coxe Hippisley, one of the original Managers, presented "A Voyage round the Mediterranean" by Lord Sandwich, and that Thomas Bernard, who, after Rumford, played the foremost and most active part in founding the Institution, presented "A View of Nature", by Richard Joseph Sulivan, a work in six volumes. Other gifts followed immediately.

In June 1799 the house in Albemarle Street, formerly the property of a Mr. Mellish, was acquired at what proved to be a bargain price, and for the next four years the Library continued to grow by means of many generous gifts and by purchases made under the orders of the Managers. The story of these early years can be traced from the Minute Books and from early reports on the state of the Institution written by Count Rumford and published in the first volume of the *Journals of the Royal Institution*. The Library in those days was situated on the ground floor, and consisted of a conversation room and two reading rooms. In the conversation room, 'Proprietors' and 'Subscribers' (the terms used for the members) could obtain at the most reasonable prices, according to one of Rumford's reports, soups of various kinds—doubtless Rumford's soups—tea, coffee, chocolate and other refreshments. "The Reading Room," Rumford said, "is spacious and airy . . . and as it is furnished with double windows and thin white window blinds, it is uncommonly quiet and pleasant though it is situated on the ground floor and near the street. The carriages which pass are scarcely heard through the double windows; and as the blinds prevent it being overlooked from without, it has an air of stillness and retirement which is very striking, and very pleasant to those who frequent it."

The room that is now known as the Main Library, on the first floor, was originally used as a lecture room, until the theatre was built in 1801, when plans were made for turning this room into a "Library and Collection of Reference". Rumford left the Institution in April 1802, however, and with his departure the making of new plans slowed down and the Managers rather halted to take breath and collect their thoughts for the future.

Besides the gifts which were being added to the Library, Rumford made arrangements for the regular receipt of foreign scientific journals and books of importance. The receipt of these foreign publications was quite an achievement at that time, because Britain was then heavily engaged in the Napoleoni Wars, and Rumford boasted in one of his reports i 1801 that "so effectual are the measures that hav been taken for procuring all new foreign scientifi books without delay, that they frequently come t the Institution, from the continent, while they a yet wet from the press".

Davy arrived in March 1801 and Thomas Youn a few months later. Garnett, the first professor, ha fallen foul of Rumford, and left in 1801. Young, o his arrival, immediately started to take an intere in the Library, and the minutes report several tim that he recommended the Managers to purcha certain books and journals for the Library. He mad good use of it for reference purposes, and the wel known engraving "Eminent men of science in th Library of the Royal Institution in 1807–8" indicat some of the other famous men who must have com here to use the books.

The Library was now beginning to prove its wort judging by what Thomas Bernard, the first treasure said about it in a glowing report to the Committee Visitors in 1803 on the present state and progress the Institution: "The Library and proposed collectio of books of reference will form a library establis ment honourable to the British nation, favourable science, advantageous to the pursuits of scientif men, and very conducive to the increase of the fun and of the utility, prosperity, and permanency the Institution". In 1803 a scheme was started f the formation of an additional library of referen for scientific men. This library of reference was be housed in what is now the Main Library on th first floor. The plan was to open a subscription li and everybody who contributed more than £1 would become a hereditary patron; those who su scribed between £50 and £100 would be patrons f life; and subscribers of lesser sums, whose su scriptions together came to £100 or more, cou appoint out of their number one patron for li The application of these subscriptions in providi and fitting up the Library was to be in the hands the patrons, who were also to make their own rule to appoint their own president, treasurer, secreta and committees to conduct their business. Th plan, whereby the upper library became a separa department within the Institution, was later prove unworkable; but it did achieve immedia success at first. Many famous men became patro of the Library, nearly £3,800 was subscribed with a month, and nearly £5,400 within three years— goodly sum in those days for starting a library.

With this money many valuable books were pu chased, and their selection was made with great sk and knowledge, probably under the direction of E Spencer, the chief patron. The largest purchase w made in 1804, when the entire library of print books of the late Thomas Astle, the well-know antiquary and Keeper of the Records in the Tow was bought for a thousand guineas. This libra which now came into the Institution's possessio contained, I believe, more than two thousa volumes which had mainly been collected by Astle father-in-law, the Rev. Philip Morant, author of "The History of Essex", and we still have the manuscript catalogue of this collection. It was rich n topography and history, and many of the books ontain manuscript notes in them by Astle and their previous owners. A lovely copy, bound in red morocco, of Astle's own book "The Origin and Progress of Writing", the 1598 edition of "Holinshed's Chronicles", and a collection of rare and interesting political and antiquarian tracts are among the reasures acquired in 1804. Many of these books from Astle's library would, I think, constitute a valuable source of information for historical research cholars; but their existence here is not widely known.

---

* Substance of a talk given before a meeting of the Library Circle at the Royal Institution on March 3.

In June 1803 the patrons appointed Mr. William . Harris, formerly a bookseller's assistant, to be in charge of the Library at a salary of £150 a year and the Managers allowed him to live in the House.' Harris's task was to collect and arrange the Library under the general supervision of the patrons, Dr. Charles Burney acting as honorary librarian. Harris had two assistants, one for the lower and the other for the upper room, and the Library was kept open until 11 p.m. each night.

In July 1803 it is interesting to find that Mr. T. F. Dibdin applied for the situation of principal librarian of the Royal Institution; but he was told that it was not intended to proceed to the choice of a ibrarian until after the following Christmas. Thus the Royal Institution lost the chance of employing a man who later became one of the most famous bibliographers of all time.

But Harris, who was soon afterwards formally appointed Keeper of the Library, served the Institution well. Not very much is known about him; but we have a few facts and we can assume others. He was responsible for building up and arranging the Library at the time when £5,000 was available for spending on this object, and therefore he had the fine opportunity of going to sales and purchasing many books on behalf of the Institution. Dibdin, in his "Bibliographical Decameron", when describing the famous sale of the Roxburghe Library, tells this little story. "Short men were smothered; and nothing but the standing upon a contiguous bench saved the writer of the Bibliographical Decameron from suffocation. Even the worthy Mr. Harris, Librarian of the Royal Institution, who measures some five feet 10 or 11 inches, was compelled to have recourse to the same expedient; and, in so doing, gallantly rescued (at the peril of a compound fracture n his right arm) my excellent friend Mr. James Heywood Markland from an almost overwhelming pressure."

In 1809 Harris produced the first printed catalogue, which was highly praised at the time. Dibdin, in his "Bibliomania", speaks of it thus: "If a lucid order, minute and correct description of the volumes of an admirably chosen library, accompanied with a copious and faithful alphabetical index, be recommendations with the bibliographer, the present volume will not be found wanting upon his shelf. It is the most useful book of its kind ever published in this country. Let the bibliomaniac hasten to seize one of the five remaining copies only (out of the 50 which were printed) upon large paper". Harris, I suspect, was a friend of Dibdin's! By that time the Library of Reference contained more than 12,000 volumes of the best authors and editions in every branch of science and literature, and much credit is due to Harris for the good foundations which he laid for the Library. In 1821 he produced a second edition of his catalogue.

Besides living on the premises, Harris supervised the House under Davy, and it was through an action of Harris's that the opportunity arose for Davy to make his now famous offer to Faraday in 1813 of a post at the Institution. The incident, which led to such remarkable consequences for the Institution, happened one evening in 1812 when Harris heard a commotion in the lecture room and found William Payne, the laboratory assistant, fighting with Mr. Newman, the instrument maker, on a question of attending to the needs of Prof. Brande. Harris presumably reported the matter to Davy. Payne was dismissed, and Davy, a few months later, offered the job of laboratory assistant to Faraday. Thus Harris, by a lucky chance, did more for the Institution than he ever realized. He continued as librarian until the end of 1823 when, through lack of funds, his situation was regretfully terminated. He had served the Institution well for twenty years.

The system of having the Upper Library run under the management of the patrons of the Library and the remaining rooms under the control of the Managers worked well at first; but the dual control system was bound to fail in the end. From the minutes it is obvious that from 1812 onwards the patrons were maintaining the Library with less and less effect. The original funds had been spent, few new subscriptions were coming in and by 1816 the patrons found it difficult even to pay the librarian's salary. Gradually, therefore, the Managers had to step in, and by December 1826, when William Singer was appointed librarian, it was the Managers of the Institution and not the patrons of the Library who henceforward paid his salary. The system of having patrons dragged on until the 1860's; but it gradually passed into limbo and the Library then, quite rightly, came under the direct control of the Managers.

Among the patrons of the Library there were many interesting people. Earl Spencer, who was president of the Institution for twelve years, was also president of the patrons. He took a lively interest in the formation of the Library and, with his vast knowledge and love of books, he was an ideal person to advise and direct the policy of purchasing. His own famous library at Althorp was one of the richest private libraries in Europe—it was sold in 1892 and is now in the John Rylands Library, Manchester. When the Institution missed the opportunity of employing T. F. Dibdin, Earl Spencer snapped him up and made him his librarian at Althorp.

Dr. Charles Burney, the famous musician and author, was one of the honorary librarians for eleven years until his death in 1814, and he took a great interest in the Library, its formation, its growth and its policy. Burney, of course, was famous for his charm and brilliant conversational powers, and I like to think that he must have frequently disregarded the 'Silence is requested' notice in the Main Library.

Rumford was a most generous donor of books, and we still have many volumes which were presented by him; and it is interesting to note that he went on presenting volumes of the *Phil. Trans.* for years after he left the Institution. Perhaps his feelings towards the Institution after his departure in 1802 were not quite so hard and bitter as his biographers have told us.

Sir Joseph Banks, Davy, Thomas Coutts, the banker and founder of Coutts's Bank, James Edwards, the wealthy bookseller and bibliographer, and William Wilberforce were also patrons. To these men and to the other patrons the Institution owes a debt, not only for their generosity, but also for the wisdom and care that they expended in building up the Library.

Faraday, of course, presented many books during his lifetime, and these have an intrinsic and sentimental value here. On his death he bequeathed to the Library his now famous manuscript note-books and diaries, and a number of his own printed books, some of which he had bound himself. With his customary modesty he said in his will ". . . these I offer for the Library of the Royal Institution, if the Managers should think them worth a place". He was one of the patrons of the Library, and it is certain that he took a great interest in it. In some of the old accessions registers long lists of books appear from time to time under the heading "Purchased with Mr. Faraday's concurrence".

Now the Managers, in the Institution's early days, were quite determined to maintain strict discipline over all who used the Library, and upon anybody who dared to misuse it they took most stringent action. For example, the following notice was put up in the Institution after the loss of two books from the Lower Library in 1806: "If the above books have been borrowed under the idea of a right so to do, the Managers request that they may be brought back; and that all persons will abstain in future from taking away any book, as being positively contrary to the laws of this Institution. If, however, it should appear, as in a former instance, that either of the above mentioned books has been fraudulently taken away, the Managers, being determined to subject such an offender to the utmost rigour of the Law, offer a reward of ten guineas, to be paid to the informer upon conviction".

Again, there is the story of Frederick Accum, a German chemist who worked in London and achieved considerable fame in the early nineteenth century by his inventive skill and by his publications. He became a member of the Royal Institution and was employed here for two years from 1801 until 1803 as "Assistant chemical operator"; but he continued to remain a member after resigning this post and was a frequent user of the Library. In the minutes of 1820 it was reported that Mr. Sturt, the assistant librarian, had reported that a number of books had been made imperfect by having several leaves and plates taken out of them, and that these mutilated books were those that Mr. Accum was in the habit of reading. The secretary had directed Mr. Sturt to have holes bored in the cupboard of the room adjoining the Reading Room for the purpose of watching more closely the persons who frequented that room, and on December 20 Mr. Sturt saw Mr. Accum enter the room, where he remained nearly two hours, during which time he watched him very closely from the cupboard and had no doubt but that he had torn several leaves out of a volume of *Nicholson's Journal*, which he had been reading, but owing to a pile of books which was lying on the table, he could not be positive and therefore he did not then interfere. Immediately after Mr. Accum had quitted the Institution, which he did in a hurried and confused manner, Mr. Sturt examined the books which he had seen in Mr. Accum's hands and found that Parmentier's "Treatise on the Composition and Use of Chocolate" had been taken out of *Nicholson'* *Journal*, vol. 5, which he was positive had been entir the week before. The matter was then reported t the local magistrate, who issued a warrant to searc Mr. Accum's house in Compton Street. A numbe of leaves, which Sturt identified as being torn out o books belonging to the Institution, were found. Th case was then brought before the magistrate; bu the magistrate ruled that however valuable the book might be from which the leaves found in Mr. Accum' house had been taken, yet the leaves separated fro them were only waste paper. If they had weighe a pound he would have committed him for the valu of a pound of waste paper, but this not being th case he discharged him.

The Managers, however, were not satisfied wit this ruling and resolved that a Bill of Indictment b preferred against Mr. Accum. This Bill of Indictment was preferred against him for feloniousl stealing and taking away 200 pieces of paper of th value of four pence, the property of the members o the Royal Institution of Great Britain. But by th time this second case was due for trial in April 182 poor Accum had disappeared and returned to hi native Germany, thus forfeiting his honour and £20 bail.

It seems that Accum was probably guilty o mutilating books; but one cannot help but feel tha the punishment was too harsh for the crime. Ou copy of *Nicholson's Journal*, vol. 5, with it missing pages is to-day evidence of these strang happenings.

Under Faraday, Tyndall and Dewar, the Librar continued to grow and in 1857 a new printe catalogue was published. This catalogue was th work of Benjamin Vincent, who was then the keepe of the Library, and supplements were published dow to 1914. Vincent was a scholar in his own right an edited Haydn's "Dictionary of Dates" and th "Dictionary of Biography".

In 1896 Ludwig Mond presented No. 20 Albemarl Street, and thus the Library was extended by th addition of two more rooms.

Henry Young succeeded Vincent as librarian, an Mr. Ralph Cory, as he recently related in his discours on "Fifty Years at the Royal Institution", joine Young in 1899. Mr. Cory was in charge in 193 when the Library was redesigned and rebuilt, and h faced the immense problems of disposing of the book while this work was going on and then in re-shelvin them when it was completed.

The contents of the Library cannot be describe here; but it still possesses among its 65,000 volume many early works of interest. A fine copy of th 1543 edition of "De Humani Corporis Fabrica" b Vesalius; the 1499 Aldine edition of "Astronom Veteres"; a first-edition copy of Gilbert's "D Magnete", 1600; Burton's "Anatomy of Melancholy in the 1652 edition; Hooke's "Micrographia", 1667 Schott's "Technica Curiosa", 1665; Ramelli' "Diverse et Artificiose Machine", 1588; and a fin set of Gould's "Birds" are a few examples chosen a random. But the Library, which is particularl strong in its sets of periodicals, 350 journals bein currently received, is not confined to science, an contains works on history, topography, literature an other subjects, many of which are of considerabl interest. This fine collection is kept here for th purpose of serving the Institution's object, which i the promotion of science and the diffusion an extension of useful knowledge.

THE NATURE OF PLANT SPECIES

NEBULOUS and indefinable as the ancient concept of the species may be, discussion of it continues to be profitable in providing the opportunity for reviewing progress in the study of the variation of living organisms and of reassessing the taxonomic methods whereby existing knowledge is recorded and catalogued. Not unexpectedly, this proved the main function of a conference arranged by the Botanical Society of the British Isles on "The Species Concept in Relation to the British Flora", held in London at Church House, Westminster, during April 9–10. In the unfortunate absence of the president, Canon C. E. Raven, this fourth conference of the Society was opened by Prof. T. G. Tutin (University College, Leicester). The programme followed the pattern of former years, with formal papers, exhibits and a concluding field excursion—on this occasion, jointly with the British Bryological Society, to Box Hill, Surrey, under the leadership of Mr. E. C. Wallace.

With the efflorescence during recent decades of so-called experimental taxonomy, it is not surprising that several of the papers read at the conference should have been concerned with the impact of experimental studies on the species problems of orthodox taxonomy, and that applications of new techniques were to be seen among the exhibits. Prof. S. C. Harland (University of Manchester) was regrettably prevented from being present through illness, and his paper was read by Miss H. Jackson. In it, Prof. Harland said that the aim of experimental studies on plant populations is not primarily taxonomic revision, but rather to formulate relationships in terms of genes, chromosomes and cytoplasm. Data useful for classificatory purposes arise more or less as a by-product, and the occasions when experimental results actually demand radical taxonomic revision are relatively few. Crossing is the most familiar experimental method; but graftability provides an index of relationship not often taken into account. A successful graft between two species must indicate relatively close biochemical relationship between their tissues, and the evidence available from horticultural experience, in Rosaceae, Solanaceae, etc., has significant implications. On the whole, it appears that grafting is not possible between representatives of different families, and the correlation between inter-graftability and capacity for sexual hybridization is quite good. The evidence from grafting experiments combined with that from hybridization has provided justification for taxonomic changes such as, for example, the fusion of the genus *Erioxylum* with *Gossypium*.

Discussing the taxonomic problems arising from variability within species, Dr. J. H. Burnett (University of Liverpool) said that it has been customary to give nomenclatural recognition only to those infra-specific units which are readily detectable through their morphological distinction, and these are not necessarily the most important from the point of view of the survival and behaviour of the species. Heritable infra-specific variation may be genic, chromosome numerical or chromosome structural in origin, and, from the point of view of a morphologically based taxonomy, the variants may be manifest or cryptic. Single gene differences are likely to gain taxonomic recognition when they affect a feature like flower colour, but less so when they concern a characteristic like glucoside content, as in *Trifolium repens*. Races differing in chromosome number may show a wide range of morphological distinctness. In the British flora, cytologically heterogeneous species exist like *Iris pseudacorus* in which no serious attempt at taxonomic subdivision has been made because of apparent morphological homogeneity, while in other instances (for example, *Monotropa hypopithys* and its segregate *M. hypophegea*) taxonomic subdivision preceded the discovery of cytological heterogeneity. Populations differing in chromosome structure are found within such species as *Datura stramonium* and *Paris quadrifolia*; here again, from the point of view of orthodox taxonomy, much of this type of variation is cryptic. The exhibits of Dr. C. T. Prime and Mr. G. Panigrahi illustrated some of the complexities introduced by the existence of cryptic or semi-cryptic cytotypes within flowering plant species, the former dealing with *Arum maculatum* and *A. neglectum*, and the latter with *Caltha palustris*, in which a truly astonishing range of chromosome numbers has been reported.

The relationship between the categories of the older and newer 'taxonomies' was discussed in papers by Dr. J. Heslop Harrison (University College, London) and Mr. J. S. L. Gilmour (University Botanic Garden, Cambridge). Dr. Heslop Harrison stated the case against any attempt to give narrow genetical definitions to nomenclatural taxonomic categories, and particularly to the species, pointing out that in practice binomials are given to variational units of many different types. Even with outbreeding sexual organisms, uncompromising genetical definitions, based, for example, on fertility/sterility criteria, are either inoperable in practice or produce results widely at variance with those arising from the use of criteria derived from comparative morphology. The more subtle biological species concepts such as that of Mayr have abandoned any pretence of providing an experimental test of species status, and in effect ultimately come simply to describe some of the biological properties of the 'good' species of taxonomy. If the categories of nomenclatural taxonomy are maintained with their present general-purpose application, the need may still exist for special classifications based upon genetical, cytological or other special criteria in genecological and similar research. It remains questionable, however, whether a 'taxonomic' approach is now required at all in evolutionary studies, where the requirement is to investigate processes rather than to recognize stages. Mr. J. S. L. Gilmour said that all classification should have a purpose, and that the attributes chosen for the construction of classifications are naturally selected with regard to their purposes. Orthodox taxonomy has achieved a high measure of success in producing a classification of the plant kingdom based principally on morphological attributes, taking distribution also into account. The so-called experimental taxonomy, with its concern for the processes of micro-evolution, has different aims and therefore adopts different criteria. The facts discovered in experiment may, of course, have relevance to orthodox taxonomy, but it would be a mistake to attempt to absorb the experimental categories into nomenclatural taxonomy in the belief that the latter would thereby be 'improved'. Disagreement still exists as to how the experimental categories themselves should be defined, and already in this field terminology is chaotic. It is with the hope of introducing some semblance of order that a development of the 'deme' terminology[1] has recently been formulated after discussion between several British genecologists and taxonomists. The use of Turesson's genecological category system was illustrated in a paper by Dr. C. H. Andreas (University of Groningen), who, describing the Dutch forms of *Stellaria nemorum*, said that while there might be doubt as to the appropriate taxonomic ranks to be given to these, they are to be looked upon as ecotypes, being clearly differentiated in their ecological tolerances.

Dr. H. Hamshaw Thomas (University of Cambridge), in directing attention to the stability of many specific characters as revealed by the fossil record, provided a valuable counterbalance to the impression of complete fluidity so easily gained from many present-day discussions of the species problems of flowering plants. There are few fossil records of angiosperms continuous over long periods of time such as exist in various animal phyla, but from the available evidence it is clear that certain generic and even specific characters have been extraordinarily stable. Identifications of the leaves of genera such as *Acer*, *Betula* and *Populus* in early Tertiary deposits have been amply confirmed by wood and pollen studies. Remains of flowers are not abundant, but such as are available—*Populus* and *Cinnamomum* in Oligocene amber, for example—testify to the antiquity and stability of present-day types. Certainly there is little in the record to support the concept of gradual evolution from a proto-angiosperm with flowers consisting of a mass of 'fertile leaves'.

The increasing importance being attached to vegetative features in the treatment of critical taxonomic groups among modern flowering plants was illustrated by papers contributed by Prof. T. G. Tutin and Dr. R. Melville (Royal Botanic Gardens, Kew). For several reasons, not the least being their lesser liability to environmental modification, floral parts provide most of the technical diagnostic features cited in Floras; nevertheless, said Prof. Tutin, the experienced field botanist recognizes most of his plants by their general appearance, to which vegetative features contribute by far the greatest part. In many anemophilous alliances, the reduction and standardization of floral pattern is such that few diagnostic features can be derived from this source in any case, and in families like Chenopodiaceae and Gramineae, discrimination of species requires the adoption of other criteria, including habit, colour, and vegetative and anatomical characters, many of which can only be assessed by measurement. Among British grasses, anatomical features have for some time been used for the recognition of critical taxa, and more recently features of the leaf epidermis have proved valuable for the separation of species not readily distinguishable in other ways. They can, for example, be used to discriminate *Puccinellia distans* and *P. pseudodistans*, and provide justification for the recognition as a separate entity of the enigmatic Irish taxon, *Puccinellia maritima* var. *hibernica* of Praeger and Druce. Dr. Melville explained the significance of characteristics derived from the foliage of arboreal species where the flowers are either not available or useless as a source of taxonomic characters. Although leaf shape may show great variation during growth, the sequence observed from youth to maturity and from the beginning to the end of a season's growth follows a consistent plan, and such a sequence—the leaf spectrum—may be treated as a single complex character. A study of elm hybrids suggests that the factors controlling leaf shape in one part of the leaf spectrum may be mainly derived from one parent, while those controlling another part may be inherited from the other. The spectrum may thus vary in a complex manner; but is not beyond interpretation with a knowledge of the characteristics of the parents.

The taxonomic problems of cryptogams were discussed in papers by Prof. I. Manton (University o Leeds), Prof. A. Burges (University of Liverpool) and Dr. E. W. Jones (University of Cambridge) and illustrated by exhibits by Dr. S. Walker, Mr. J. D. Lovi (both of the University of Leeds) and Dr. E. Burrow and Dr. S. M. Lodge (both of the University of Liverpool). Surveying the recent work of the Departmen of Botany of the University of Leeds on the cytotaxonomy of ferns, Prof. Manton stressed that with pteridophytes, as with flowering plants, the morphologically based species of taxonomy generally embrace complexes of infraspecific units distinguishable by physiological, cytological or other characteristics. In such common British species as *Asplenium adiantum-nigrum*, *A. trichomanes*, *Polypodium vulgare* and *Cystopteris fragilis*, different cytotypes exist which possess independent geographical distributions and ecological tolerances. Understanding of these species requires knowledge of the world distribution of the component races, while the inter-relations of the races themselves can be examined by the analysis of chromosome pairing in artificial hybrids between them The results of the examination of the distributional patterns of the cytotypes are occasionally found to contradict generally held principles derived from angiosperm studies. Thus the thesis of a correlation between increasing levels of polyploidy and increasing latitude finds no general support from fern cytotaxonomy. A preliminary survey of the fern flora of Ceylon in which 60–70 per cent of the known species have been examined cytologically shows that in this tropical island some 60 per cent of the species are polyploid, compared with 53 per cent in the British Isles where all species have been investigated. Similarly, within species, it is often found (as, for example, with *Cystopteris fragilis* and *Dryopteris dilatata*) that it is the races of lower chromosome number which possess the more northerly ranges. In exhibits dealing with fern cytotaxonomy, Miss M. G. Shivas dealt with the relationship of the two subspecies of *Asplenium adiantum-nigrum* in Britain, Dr. S. Walker presented data on the *Dryopteris spinulosa* complex in Europe, and Mr. J. D. Lovis illustrated work on the problem of *Asplenium trichomanes*. The last-named case is typical of many arising with pteridophytes, where diagnostic characters have perforce to be drawn mostly from foliar characters which are notoriously plastic. No qualitative differences have been found to separate the two cytotypes of *A. trichomanes*, although they are distinguishable on the basis of quantitative characteristics including, especially, spore size.

Commenting on the problems of fungal systematics, Prof. A. Burges said that many of the difficulties encountered with flowering plants exist, often in aggravated form, together with others peculiar to the group arising from the special genetical mechanisms found in it. Heterokaryosis, for example, provides a mechanism of variation unparalleled among the higher plants, and there have been few attempts to develop new concepts of species in the fungi to take such phenomena into account. The difficulties which arise in all biological taxonomy from the fact that what is being classified is a 'slice' at a given time of an evolutionary continuum are emphasized in genera such as *Puccinia*, where a short generation time means a very much higher potential evolutionary rate. Wheat rust races in Australia have been known to replace each other over an area of continental dimensions in periods as short as two years. Phenotypic plasticity—a source of difficulty in higher plant systematics—is often encountered in extreme form in fungi. The different manifestations of the same organism on different hosts, or even on different parts of the same host, are sometimes so dissimilar as to have led to their classification in different genera. Only culture techniques can serve to clarify situations such as these; but, even so, problems of typification and nomenclature remain acute.

Biochemical and other physiological criteria have become of importance in fungal and bacterial systematics; but so far they have not assumed significance n the classification of the bryophytes, although, as emphasized by Dr. E. W. Jones, the search for new taxonomic characters in this group continues. Early bryophyte systematists placed reliance largely upon gross morphology of vegetative and reproductive organs; but, more recently, anatomical and histo-ogical characters have assumed primary importance n species discrimination, and even cytological features ike the presence and nature of oil bodies in the living cells. All parts of the bryophyte thallus seem to be susceptible to environmental modification, and recent critical culture work which has demonstrated that many described forms are not genotypically distinct has led to the relegation to synonymy of many species names. There is little agreement, however, as to what shall be taken as species limits, and the tendency is o call every recognizably different genotype a species however slight its distinctive features. The apomictic reproduction of minor variants by vegetative means adds to difficulties here. Dr. Jones pointed out that any theoretical difference between the species concept as applied to bryophytes and to phanerogams lies in the fact that the bryophyte plant is the gametophyte whereas the phanerogam plant is the sporophyte. Hybridization has thus unusual consequences: it is possible, for example, to have a hybrid capsule attached to a non-hybrid gametophyte. Hybridization can also complicate algal systematics, and in their exhibit Dr. Burrows and Dr. Lodge demonstrated how the hybrid index technique devised by Anderson for flowering-plants has proved applicable to the analysis of hybrid swarms involving British species of *Fucus*. Environmental modification is also a complicating factor in this genus. Variation in *Fucus vesiculosus* and *F. inflatus* shows some degree of ecological correlation, and, in rough water, plants of the two species are very similar in their growth form. Cultural methods have been devised, and are expected o reveal whether or not the named habitat forms of the two species have a genotypical basis.

The importance of the development of culturing methods was also apparent in exhibits illustrating current work on British flowering-plants. Mr. P. F. Yeo (University of Cambridge) showed how taxonomic problems in the semi-parasitic genus *Euphrasia* are amenable to investigation now that the technique of cultivation using *Plantago lanceolata* as a host has been perfected; the relative significance of environmental and hereditary effects can now be assessed and the reproductive biology studied. Mr. D. H. Dalby (University College, London) has developed a suitable technique for the cultivation of the salt-marsh genus *Salicornia*. He demonstrated how in this genus, where reduced floral structure has resulted in a reliance on vegetative features for the discrimination of taxa, progeny tests have shown variation in habit to be hereditary in some instances and environmentally conditioned in others. Two cytological series, a diploid and a tetraploid, exist in southern England, and parallel sequences of habit-types occur in each.

Hybridization as a complicating factor in the taxonomy of critical groups was illustrated in the exhibits of Miss W. T. M. O'Connor (University of Liverpool) and Mr. P. Gay (University College, London). Miss O'Connor showed how hybrid swarms involving *Centaurium littorale* and *C. minus* could be analysed by the use of Anderson's hybrid index technique, and Mr. Gay provided new data on the variability of *Erica ciliaris*, a Lusitanian heath which in Britain, at the northern end of its range, is apparently severely affected by hybridization with *Erica tetralix*. Mr. Gay put forward the hypothesis that the Irish *E. mackaiana* may be the product of the hybridization of *E. ciliaris* and *E. tetralix*.

In the concluding paper of the conference, Dr. W. B. Turrill urged a 'synthetic' approach to the taxonomic problems remaining in a flora like that of the British Isles, where the methods of comparative morphology are approaching the limits of their usefulness. Being opposed to any segregation of experimental from orthodox taxonomy, he felt that taxonomists should be prepared to use any kind of character which might help to make a more widely useful classification. He was particularly insistent that the methods of synthetic taxonomy are in no sense closed to the amateur botanists who form the greater part of the membership of the Society: in fact, they open up to the amateur a new and largely untouched field in which almost any effort will contribute new knowledge.

In an evening meeting during the conference, Prof. A. R. Clapham (University of Sheffield) and Dr. S. M. Walters (University of Cambridge) reported to guests and members the considerable measure of progress made in the organization of the scheme for the production of a distribution atlas of the British flora, since guarantees of support for the project had been received from the Nuffield Foundation and the Nature Conservancy. Details of the scheme have been discussed by Dr. Walters in a recent article[2].

The smooth progress of the conference was largely due to the work of Dr. J. G. Dony, in charge of the organization. It is expected that the full proceedings will be published in book form.

TOTAL SOLAR ECLIPSE OF JUNE 30

BRITISH EXPEDITIONS' RESULTS

By PROF. R. O. REDMAN, F.R.S.

ON account of several favourable factors, extensive preparations were made by European astronomers to observe the total solar eclipse of June 30; totality was of reasonably long duration, 2½ min. on the centre line, the sun was in a good star field, weather prospects were reasonably promising, and the belt of totality was easily accessible in Norway and Sweden. This article is an account only of the activities of British observers, on the ground in Sweden and in the air north of Britain.

In general, the actual weather conditions were disappointing. The chances of a clear sky had been rated highest (a little more than 50 per cent) for the coasts of Sweden, and the east-coast island Öland had been chosen for the site of many expeditions. Öland, however, with most of the Swedish mainland, was covered with thick cloud and so far as is known few observations of any value could be made there.

Farther east and somewhat off the centre-line, the island of Gotland had a good sky, while on the west coast of Sweden, to which most British astronomers had gone, totality was seen through thin cloud. In addition to conventional ground parties, a number of aircraft flew to various parts of the totality belt, north of the Shetlands and north-westwards towards Greenland, with results mentioned in more detail below.

The Royal Greenwich Observatory supplied two parties of observers. Dr. R. d'E. Atkinson went to Öland, to continue work done by him at the 1948 and 1952 eclipses, when he had made photographs of the solar crescent near totality for geodetic purposes and also to study the profile of the moon's limb. On the west-coast island Syd-Koster, near Strömstad, Mr. T. Gold and Dr. A. Hunter, with assistance from Messrs. D. W. Sciama and E. W. Bastin, had erected a 7-in. refractor of 21 ft. focal length with the purpose of photographing the star field around the sun, to measure the relativity displacement. In such work the star images can be distinguished against the background of corona only if general conditions are very good; but on this occasion the sky was not perfectly clear and scintillation was moderate, so that the photograph obtained shows little but corona. The work, however, gave valuable experience with a novel telescope shelter which might well be copied at future eclipses.

Also on Syd-Koster was a group from the Cambridge Observatories, Prof. R. O. Redman, Dr. D. W. Dewhirst, Dr. H. von Kluber and Dr. A. H. Jarrett (of the St. Andrews Observatory), alongside a group from the London University Observatory, Prof. C. W. Allen, with Messrs. C. R. Spratt, E. W. Foster and A. S. Assad. These two groups were given much general assistance by Mrs. L. von Klüber, Mr. M. F. Ingham and Mr. Jan Högbom. Prof. Redman photographed the chromospheric spectrum using a large slit spectrograph of 24 ft. focal length, with an unusually good plane grating lent by the Mount Wilson and Palomar Observatories. The spectrograph was fed by a coelostat and a concave mirror of 36 ft. focal length. Both second and third contact photographs were considerably under-exposed, mainly on account of the poor sky. Drs. von Kluber and Jarrett were engaged in an experiment which has been repeatedly tried without success by various eclipse observers during the past twenty-five years, namely, to photograph the corona in the light of the green line at 5303 A., doing this through a Fabry–Perot interferometer so that the fringes are superposed on the picture. From measurement of the fringes one may hope to obtain information of local movements and rotation of the corona, and of the distribution of kinetic temperature. The strength of the green coronal line varies with the sunspot cycle; the eclipse fell at sunspot minimum in a time of quite exceptionally low solar activity, and the 5303 A. line was known from coronagraph observations to be unusually faint. Despite all the unfavourable conconditions, successful photographs were obtained showing interference fringes, a tribute to the extreme care and thoroughness with which the apparatus had been designed and prepared. With the third Cambridge instrument, a quartz (slit) spectrograph fed by a concave mirror of 8 ft. focal length, Dr. Dewhirst obtained good photographs of the ultra-violet chromospheric spectrum at both second and third contacts. These are to be used to measure the electro temperature of the chromosphere by Zanstra' method.

The London University Observatory's programm was aimed specially at the outer corona and wa therefore considerably affected by the thin cloud The full programme of work was carried through but to what extent the sky has affected the result will only be known after measurement of the plates Prof. Allen and Mr. Spratt took a series of calibrate photographs of the corona, some in blue and som in red light, using two cameras mounted on the sam polar axis (focal lengths ~ 1 metre). At abou 7 metres in front of each camera, on its optical axis was an occulting disk designed to remove the inne corona, or to reduce its light in a pre-determine way by vignetting, so that a great range of surfac brightness in the corona could be covered satisfactoril in one exposure. The two disks were mounted on wooden tower and driven laterally at the appropriat speed to retain alignment with the cameras durin totality. Meanwhile, with a second instrument, fast one-prism slit spectrograph having an *f*/1 camer of the Maksutov type, Mr. Foster and Mr. Asa obtained a number of photographs of the corona spectrum. The spectrograph was fed by a coelosta and small telescope, and in the optical train precedin the slit was an occulting bar having essentially th same purpose as the occulting disks of the direct photograph cameras.

On Öland the St. Andrews University Observatory represented by Prof. E. Finlay-Freundlich, co operated with the Potsdam Observatory in a thoroug and elaborate attempt to observe the relativity displacement of stars near the sun. The expeditio shared the complete disappointment of many other in this part of Sweden.

Of various observations from the air, two deserv mention. Mr. J. Paton, of the Department of Natura Philosophy, University of Edinburgh, was a passenge in an R.A.F. machine flying to the belt of totality as part of a navigational exercise, and during eclips tried without success to detect a daytime aurora with the help of interference filters isolating the gree auroral line. Although the attempt was made in zone of high auroral frequency, it was not favoure by the present very low level of solar activity, whic is likely to be associated with an absence of stron auroræ.

Important work was carried out by Dr. D. E Blackwell and Mr. J. P. Hignell, of the Cambridg Observatories. With very generous assistance fron the R.A.F., they photographed the outer corona i exceptionally good sky conditions (and in considerable personal discomfort), through the open door of special Lincoln bomber flying at about 30,000 ft They used a specially designed multiple camera giving eight images simultaneously on one plate, o varying intensities and polarizations. The object wa to get better measures of the surface brightness an polarization in the outer corona, where existing dat are known to be unreliable, to a greater distanc from the sun than would be possible with observation from the ground.

At Cambridge, where the optical eclipse was partial measurements of solar radio noise were made by th Cavendish Laboratory's radio astronomy team unde Mr. M. Ryle. Since much of the radio radiation arise in the corona there is no great advantage, excep possibly at very high frequencies, in restrictin observing sites to the belt of optical totality. Th

Cambridge observations, made on five wave-lengths over the range 0·6–8 metres, aimed at checking results obtained in other ways for the distribution of radiation emission over the corona.

Observers from the Royal Greenwich Observatory were financed by the Admiralty, while those from the Cambridge and London University Observatories were supported almost wholly by a Government grant from the Royal Society through the Joint Permanent Eclipse Committee. St. Andrews observers were also supported in part from this grant. The astronomers concerned have also been grateful for generous assistance from other sources. Much help was received from the R.A.F., and also from the Swedish authorities, who through Prof. Y. Öhman, of the Stockholm Observatory, made arrangements to facilitate travel, Customs inspection, etc., in Sweden. Residents in Sweden living near eclipse camps treated the visiting astronomers with great kindness.

In addition to regular observers engaged on specific programmes of investigation, a party of about 140 members of the Royal Astronomical Society and the British Astronomical Association saw the eclipse through thin cloud in western Sweden, and a small number of others viewed it from aircraft north of Britain.

OBITUARIES

Dr. O. J. R. Howarth, O.B.E.

Dr. O. J. R. Howarth, who died on June 22 at the age of seventy-seven, was one of the earliest recruits to the Oxford School of Geography after he had taken the Final Honours School of Modern History in 1900, and geography remained his professional interest throughout his life. He edited the "Oxford Survey of the British Empire" in 1914 with Prof. A. J. Herbertson and wrote a number of text-books for the Oxford University Press. Later he became specially interested in protecting the countryside and in town and country planning, and in 1937 he wrote "The Scenic Heritage of England and Wales" for the Council for the Preservation of Rural England. He was president of Section E (Geography) of the British Association in 1951 and president of the Geographical Association in 1953, when his address dealt with the importance of teaching geography from a Commonwealth point of view.

His major occupation, however, was the secretaryship of the British Association, which he held for thirty-seven years—from 1909 until 1946. During this time the activities of the Association underwent considerable changes, as with the general recognition of the national importance of science and scientific research, for which it had striven so hard in the nineteenth century, some of its functions were gradually taken over by other bodies. The Association owes a great debt to Howarth for his long and devoted service, and to the skill and economy with which he carried on its administration with a very small permanent staff. I know from my own experience how grateful successive local secretaries, who had to organize annual meetings of increasing size, were to Howarth for his wise advice and guidance on all the details of the arrangements on which the smooth working of the meetings depended.

The future of the Association, how it could best fulfil its purpose under changing conditions, was the constant thought in Howarth's mind, and his knowledge and experience was of the greatest value to successive general officers. One great service he rendered was his short history of the Association, "A Retrospect, 1831–1931". It gives in a short compass a masterly sketch of the fortunes of the Association during its first century. In it Howarth concentrated the results of many years of study, and from his knowledge of the outstanding personalities and episodes, and with his crisp, clear style, he showed how much the Association had contributed to the advancement of British science. The idea of the book was first suggested in 1919 by Sir Charles Parsons, who made a generous contribution towards the cost of its publication in 1922. Later, again at his suggestion and with his help, it was revised and brought up to date for the centenary meeting of the Association in London in 1931.

During the long presidency of Sir Richard Gregory during the Second World War, interest in the Association was kept alive by a series of conferences on topics of immediate public concern and on the problems that would arise when war ended. Their success owed much to Howarth's untiring enthusiasm and hard work. It was his great satisfaction to see the Association emerge in 1945 stronger in heart than ever and ready to assume even larger burdens.

Most modest as to his own ability, quiet and unassuming, Howarth valued above all else in his career the opportunity the British Association gave him to enjoy the friendship of some of the leaders of science, and with their help to uphold its great traditions. He was looking forward eagerly to the meeting next September in Oxford and to renewing memories of the 1926 meeting with the small band of survivors; but that, alas, was not to be. Almost his last act was to prepare a script for the British Council on the history of the Association; but he died before he could record it.

Mr. E. F. Law

By the death of Edward Fulton Law on May 22, in his seventy-seventh year, the profession of metallurgy loses one who had been closely identified with the rapid progress which has been made both in ferrous and in non-ferrous metallurgy during the past fifty years—as a contributor to the proceedings of the Iron and Steel Institute and to those of the Institute of Metals and as a partner in a firm of consultants (Messrs. Riley, Harbord and Law, of Westminster) until the time of his death.

With a background of training which included chemistry under Tilden at the Royal College of Science (1894–98) and metallurgy under Roberts-Austen at the Royal School of Mines and at the Royal Mint (1898–1902), Law was one of a group of young men (among whom were H. C. Jenkins, A. Stansfield, W. H. Merrett, O. F. Hudson, G. D. Bengough, H. C. H. Carpenter and Walter Rosenhain) who came directly under Roberts-Austen's stimulating influence, and in all of whom the spirit of inquiry had been quickened by spending varying periods in his private laboratory at the Mint. It was there that Law took part in the work of the Alloys Research Committee of the Institution of Mechanical Engineers, which was still in progress at the time when the recently published Fifth Report had done so much to arouse interest in the application of the pyrometer and the microscope to industrial problems.

It was, in fact, in the rapidly developing art of metallography at the turn of the century that Law's exceptional manipulative skill found full expression. This is abundantly shown by the quality of the photomicrographs which appear in his contributions to the publications of the Iron and Steel Institute, to those of the Institute of Metals and particularly perhaps those which appear in the successive editions of his work on "Alloys and their Industrial Applications", first published as one of Griffin's Metallurgical Series of text-books in 1909. The frontispiece to that volume, a reproduction in colour of heat-tinted micro-sections, is one of Law's skilful adaptations of the facilities afforded by the autochrome plates (which had just been introduced by MM. Lumière, of Lyons) to differentiate micro-constituents under high powers. This early application of colour photography to metallographic work formed the subject of a short paper to the Iron and Steel Institute in 1908 and attracted the attention and interest of the Royal Microscopical Society and of the Royal Society of Arts, to which bodies a number of examples were exhibited.

After a period of private practice in Westminster, from 1903 onwards, Law became associated with the late F. W. Harbord (of Messrs. Riley and Harbord); but shortly before the First World War he accepted an appointment with Messrs. Sir W. G. Armstrong Whitworth and Co., Ltd., at their establishment a Openshaw, Manchester, where he remained unti 1922 in charge of the production of armour-plate He then returned to Westminster as a partner in th firm with which he had been formerly associated. I 1939, however, at the outbreak of the Second Worl War, his previous links with those responsible fo naval construction had led to a request by th Admiralty that he should join the late Sir Stanle Goodall at Bath. He remained there during th earlier years of the War, afterwards returning t Westminster on the death of his partner, Mr. F. W Harbord, to resume his consulting practice, i association with Mr. Vernon Harbord and Mr. T. G Howard.

Mr. Law was an associate of the Royal School o Mines and a Carnegie silver medallist. After serving for many years on the Council of the Iron and Stee Institute, he was elected an honorary vice-presiden of that body in 1950. He was also an original member of the Institute of Metals. His engaging personality and long experience in helping to solve many o the difficulties with which engineers and metallurgists had been confronted had brought him valued friendships throughout Great Britain.

S. W. SMITH

NEWS and VIEWS

Mining at Sheffield: Prof. I. C. F. Statham

PROF. IRA C. F. STATHAM, who has just retired from the chair of mining in the University of Sheffield, was born in Staffordshire and was educated at the University of Birmingham. He went to Sheffield in 1919 as a lecturer in the Mining Department and succeeded the late Prof. Douglas Hay as head of the Department in 1925. In his early years on the staff he carried out a number of researches on the ventilation of mines and ancillary problems, and later, as head of the Department, he continued to initiate and supervise research on this and other aspects of mining. He was responsible for the initial fundamental research work concerning flame-proof enclosures for mining electrical apparatus, and the subsequent routine testing and development of mining switchgear. His services as a consultant have been much in demand both in Britain and abroad, and his outstanding contributions to mining education and research have been recognized by the awards of the Futer's Gold Medal of the National Association of Colliery Managers, the Thornton Medal of the Association of Mining Electrical and Mechanical Engineers and, more recently, the Douglas Hay Medal of the Institution of Mining Engineers. He is a past-president of the Midland Institute of Mining Engineers, a vice-president of the Institution of Mining Engineers and a past-president of the Institute of Mine Surveyors. When Prof. Statham went to the Department, he found it housed in a few rooms at the front of the Applied Science Building; but in 1932 it acquired a new and larger building, and this, in 1953, was extended to meet the expanding requirements of the reorganized coal mining industry. These extensions and developments have been largely his responsibility. Although he reached the retiring age in 1952, he was invited to stay on for a further two years to complete his labours in creating the large Mining Department, fully equipped for modern teaching and research, that to-day stands as a lasting tribute to his tenure of the Sheffield chair.

Prof. F. S. Atkinson

PROF. STATHAM is being succeeded by Mr. F. S. Atkinson, at present assistant to the production director of the North Eastern Division of the National Coal Board. Mr. Atkinson was educated at Chesterfield Grammar School and the University of Sheffield, where he graduated B.Eng. with honours and obtained the Diploma in Mining in 1922, at the same time serving his apprenticeship at the Tinsley Park Colliery Co. From 1924, Mr. Atkinson was successively assistant to the manager of Frickley Colliery and manager of Hatfield Main Colliery until his appointment to the chair of mining in the University of Leeds in 1936. He resigned from the chair in 1941 on his appointment as mining agent of Upton Colliery. In 1946 he was appointed chief mining engineer of the Indian mines owned by Shaw Wallace and Co., Ltd., which post he held for three years until he went to his present position with the National Coal Board. Mr. Atkinson thus has a wide knowledge of the mining industry, both in Britain and abroad; he has published numerous articles in mining journals.

Theoretical Physics at King's College, London: Prof. C. Domb

THE appointment has been announced of Dr. Cyril Domb to the chair of theoretical physics in the University of London at King's College. Dr. Domb was a major scholar of Pembroke College, Cambridge, from 1938 until 1941 and graduated by way of the Mathematical Tripos. During 1941–46 he was at the Admiralty Signals Establishment and from 1946 held a senior research fellowship at the Clarendon Laboratory, Oxford. Since 1952 he has been a University lecturer in mathematics at Cambridge; he was awarded the Rayleigh Prize in 1949. Dr. Domb is distinguished for his work on the solid state, paricularly in relation to the statistical mechanics of o-operative phenomena.

Higher Technological Education in Great Britain

In reply to a question in the House of Commons on July 20, the Chancellor of the Exchequer stated hat the plans announced for development of higher echnological education in Leeds and Birmingham apply only to work in the universities, and do not nclude the upgrading of technical colleges. A considerable constructional programme is being carried out with the assistance of non-recurrent grants to improve and enlarge the accommodation at univerities for technological work, and the cost of the new buildings for these studies which have been started n 1953 and 1954 is estimated at about £2·7 million, nost of which will be met by grant.

A memorandum on higher technological education drafted by the Parliamentary and Scientific Committee before the Chancellor of the Exchequer made his first statement on July 13 states that there is a considerable unsatisfied demand for scientists, engineers and other technologists in British industry, particularly for metallurgists and chemical engineers and those able to take posts in management or production. This demand is expected to grow, and the Committee considers that further government action to improve facilities for higher technological education is urgently needed. So far as the universities are concerned, the Committee recommends an ncrease in the proportion of students of science and echnology within the present limits of student numbers, and expansion of postgraduate facilities particularly in fields of study of importance to local industrial interests. It also recommends extending the conditions of admission to postgraduate work and an ncrease in the number of bursaries from government and industrial sources. As regards colleges of technology, the Committee recommends that a limited number, ultimately twenty, of colleges of technology should be given charters as royal colleges of technology, with the maximum academic autonomy, and financial independence on a quinquennial basis such as the universities enjoy, subject to a special grants committee closely co-operating with the University Grants Committee. Both the regional advisory councils and the local authorities of the region would be represented on the governing bodies as well as cientific, technological, industrial and commercial nterests. The colleges, which would include a reasonable infusion of the humanities in the courses, would be entitled to award the degree of bachelor of technology, and this should be of sufficient standard to qualify its holder for postgraduate work in a university. The memorandum refers also to the shortage of science teachers and the need for intensive and long-erm efforts by industry and the professional nstitutions to break down the prejudice of those leaving school against careers in applied science, as well as the need for greater co-operation between ndustry and the universities and technical colleges n the interchange of staff and in other ways.

Financial Estimates for the Department of Scientific and Industrial Research

In reply to questions in the House of Commons on July 20 regarding the Department of Scientific and Industrial Research, Mr. J. R. Bevins, Parliamentary Secretary to the Ministry of Works as representing the Lord President of the Council, said that the estimates for the present financial year provide for an increase in gross expenditure of £71,440 and an increase of staff of 197 compared with last year. It is expected that about fifty of the additional posts will be filled by industrial staff, and most of the others will be in the scientific officer, experimental officer and assistant (scientific) classes. Provision for a further two hundred posts, of which about fifty will be for industrial staff, is planned for each of the four financial years 1955–56 to 1958–59. The present establishment at the Chemical Research Laboratory is 193 compared with 184 in July 1953, and consists of 159 non-industrial and 34 industrial staff. Nine of the present twelve vacancies are expected to be filled in the near future. The major works included in the Department's building programme for 1954–55 are the Hydraulics Research Station (£159,800), Mechanical Engineering Research Laboratory (£254,600), National Physical Laboratory (£111,700), Radio Research Station (£92,500) and the Water Pollution Research Laboratory (£115,000). The Water Pollution Research Laboratory will be completed and occupied this year, and the work at the Hydraulics Research Station should also be nearing completion. Work on the new Radio Research Station began this year and is expected to be completed in 1955–56. The provision for the National Physical Laboratory is principally for the commencement of construction of a new ship tank (for research and testing on the form of ships' hulls and propellers), which is expected to take some four to five years to complete.

Heavy-Water Reactor (Dimple) at Harwell

The United Kingdom Atomic Energy Authority has announced that a heavy-water reactor (or atomic pile) which has been built at the Atomic Energy Research Establishment, Harwell, is now in operation. 'Dimple' is a low-powered thermal neutron research reactor. The heavy-water moderator is contained in a tank which is surrounded by a graphite neutron reflector. Outside this is a concrete radiation shield. The reactor fuel is submerged in the heavy water. Both the type of fuel and its arrangement in the tank can be changed quickly so that what is, in effect, a different design of reactor can be built up in a matter of a few days. The reactor will only be operated at very low power so that its structure does not become sufficiently radioactive to prevent the necessary handling. The behaviour of the wide variety of design can, therefore, be investigated experimentally in a relatively short time. The versatility of Dimple will make it an extremely valuable tool in the design of future power-producing reactors and for measuring essential constants in reactor physics. One of the first functions of Dimple will be to carry out experimental work for *E.443*, the new and more powerful heavy-water reactor which is now being built at Harwell to provide the high neutron flux essential for some research purposes.

European Atomic Energy Society

Representatives from eight European Atomic Energy Commissions have agreed to establish a European Atomic Energy Society (Société Européenne d'Énergie Atomique). The eight nations represented are: Belgium, France, Italy, The Netherlands, Norway, Sweden, Switzerland and the United Kingdom. The chief aim of the new Society is to promote co-operation in nuclear energy research and engineering. To achieve this the Society will: (*a*) promote the arranging at regular intervals of international meetings for scientists and engineers working in the field of peaceful application of nuclear energy; (*b*) promote the circulation of reports and other information of unclassified nature; (*c*) work for standardization of nomenclature and symbols in nuclear energy; (*d*) promote the study of hazard and safety measures arising from the application of nuclear energy; (*e*) promote publication of nuclear energy works, and possibly encourage the establishment of an international journal in the field; (*f*) establish a centre of information on availability of nuclear energy materials and equipment. Participation is limited to those nations which have already established nuclear energy projects. The statutes provide, however, that by unanimous decision of the existing members invitations to join the Society may be issued to other European Atomic Energy Commissions which, in the opinion of the Society, have established such projects.

The Society was formally established at a meeting at the Royal Society in London on June 15, at which Sir John D. Cockcroft, director of the Atomic Energy Research Establishment of Britain, was elected president of the Society for the first year. Mr. Gunnar Randers (Norway) was elected executive vice-president, and Dr. Bertrand Goldschmidt (France) vice-president. The Society will be governed by a Council consisting of one delegate from each of the eight member organizations. A working group under the leadership of the executive vice-president will take care of the activities of the Society between Council meetings. One of the tasks of the working group of the Society is to prepare international conferences on the application of atomic energy. The difference between the recently formed European Atomic Energy Society and the European Nuclear Research Centre in Geneva should be noted. The Geneva establishment will carry out pure scientific research while application of industrial atomic energy is explicitly excluded from its activities. The European Atomic Energy Society is intended as a European forum for promoting the development of industrial uses of atomic energy.

Closing of the Mushroom Research Station, Yaxley, and Transfer of Work

As a result of the arrangements made between the Mushroom Research Association, Ltd., the Glasshouse Crops Research Institute and the Ministry of Agriculture, the Mushroom Research Station at Yaxley, Peterborough, will close before the end of this year, and mushroom research will be resumed at the new Glasshouse Crops Research Institute, Littlehampton, as soon as suitable buildings and equipment are ready. Of the staff at Yaxley, Mr. P. B. Flegg, Miss D. G. Gandy and Miss I. I. Warman will join the new Institute in due course. The director of research, Dr. R. L. Edwards, will remain at Yaxley until November 30 to complete the cropping experiments now in progress and to prepare a final report; after that he will transfer to commercial mushroom-growing and practise as a private consultant. After the closing of the Station, communications concerning the research programme should be addressed to Dr. W. F. Bewley, director of the Glasshouse Crops Research Institute, at first in Cheshunt, Herts, and later at the new buildings in Littlehampton, Sussex. Requests for advice, examination of samples, etc., should be sent to the nearest horticultural officer of the National Agricultural Advisory Service, who will forward them t his regional laboratory or to the Research Institut if necessary. Information concerning internationa conferences on mushroom science can be obtaine from Dr. R. L. Edwards, at Ratcliffe Lodge, Sout Luffenham, Oakham, Rutland.

Meteoritics: a New Journal

From the time of the inception of the Meteoritic Society in 1933, its *Notes* and *Contributions* wer published regularly in the monthly magazine, *Popula Astronomy*, until December 1951, when that periodic was discontinued. By arrangement of the Council o the Society with the University of New Mexico, new publication entitled *Meteoritics: The Journal o the Meteoritical Society and the Institute of Meteoritic of the University of New Mexico* has been established The first number, consisting of an introduction an twenty-three articles, appeared in December last yea and serves as a complete issue for 1953 (pp. 123 obtainable from the Secretary of the Meteoritica Society, Dr. John A. Russell, Department o Astronomy, University of Southern California, Lo Angeles 7, Cal.; 4 dollars a year). Meteoritics i concerned with the investigation of the matter tha reaches us from space beyond the earth. Prof. F. C Leonard discusses its recent progress and futur development in a paper which includes an addres delivered at the opening of the new Institute o Meteoritics—the only establishment of its kind n the world—and a list of some fifty problems awaitin solution or requiring further research. In respons to a questionnaire as to the contributions an problems thought to be most important, Prof Harrison Brown states his conviction that study o trace elements and isotope fractionation will indicat the conditions under which meteorites were formed and Dr. F. L. Whipple lists among his major contributions the absence of hyperbolic meteorites an the recognition of planetoidal and cometary type The articles cover a wide range of interests, one o the most notable being a systematic study of th formation of craters by high-speed particles. Th new journal, which is attractively printed and illustrated, is expected eventually to become a quarterly The editors and other officers of both the Societ and the Institute are to be congratulated on a initial success which augurs well for the future o their enterprise.

The Starfish

No. 7 of *The Starfish*, the journal of the Associatio of School Natural History Societies, has recentl been published (obtainable from G. I. Crawford 18 East Drive, Carshalton, Surrey. 2*s*. to non members). The journal is edited by G. I. Crawford Major Maxwell Knight and R. S. R. Fitter. It open with a report of the annual general meeting of th Association and an account of the exhibition held o November 7 at the British Museum (Natural History) John Ounsted describes the Botanical Society of th British Isles, stressing the facilities it offers t juveniles. R. H. Winterbottom (Dulwich College records a winter census of gulls. Michael L. Elliot (West Buckland School) gives a fascinating an revealing account of how he keeps and studies adder in captivity. Patricia Brown (Orange Hill Girl Grammar School) describes how trout are kept a her school. Christopher N. G. Sell (Bishop's Stortford College) and some colleagues have been makin observations on moths with the use of a mercury vapour light-trap. The fauna of the umbels of cow parsnip (*Heracleum sphondylium*), the majority of which was insects, is described by R. G. Pearson (Dauntsey's School). R. William Boardman (Bishop's Stortford College) presents a unique ecological study—the cryptogams of a derelict cucumber house. The journal concludes with reports from member schools and some reviews of natural-history books.

Wheat Breeding in the Near East

ATTEMPTS to improve cereal production necessarily include a study of host–disease relationships. At the third meeting of the United Nations Food and Agriculture Organization on wheat and barley breeding in the Near East, held recently in Damascus, Dr. T. Abdel-Hak gave an account of work at Giza Experiment Station on the relative susceptibility of wheat varieties to stem rust, bunt and flag smut, and on the physiological races of stem rust in Egypt, Syria and Turkey. Of 236 varieties of wheat produced locally in Egypt or introduced from other countries, fourteen proved resistant to all three diseases and were thus suitable for future breeding programmes. Resistance to stem rust was less general than to bunt or smut and also varied with the physiological race of rust present, Reliance being the only variety of wheat nearly immune to all the stem rusts so far isolated in Egypt. Prevalence of the different races might change from one year to another. The same race (17) had been predominant in Egypt since 1949; but a new one (53) isolated in 1950 had greatly increased in importance by 1953. Race 17 was also predominant in Syria and Cyprus, whereas in Turkey race 14 occurred most frequently. Although certain races had been isolated in Turkey or Syria which had so far not been found in Egypt, in general there was a great similarity both in the occurrence and prevalence of wheat stem rusts in all the Near East countries. This might indicate uredospore migration, and both further research and co-operation between the various countries in the region are needed to determine the true facts of the case.

Entomology and Public Opinion

THE United States Department of Agriculture has produced an excellent booklet describing the work of professional entomologists. The booklet has been designed particularly to help the layman to understand the part played by 'pure' and 'applied' entomology in his everyday life. Its opening page shows a Dakotan farmer looking at a field of corn which has been devastated by locusts; such incidents happened in the Dakotas in 1932. They have not happened since, and the rest of the booklet, with arresting pictures and prose, describes the reasons. The protection of food from insect pests, the virtual elimination of yellow fever and malaria, the rare occurrence of plague, typhus and relapsing fever, protection against clothes moth and other insect pests in the home, are some of the topics used for illustrating the work done by government and other entomologists in the United States. Existing research projects in entomology are also described in a booklet which is to be commended as a means of helping the layman to understand the nature and purpose of science.

Application of the Electrical Potential Analyser

RESEARCH REPORT No. 22 of the Aluminium Development Association (pp. 24; from the Association, 1953; 7*s.* 6*d.*) contains a description of an electrical potential analyser for the solution of the problem of the determination of the torsion constants for bulbs and fillets such as may be used in structural sections. The report is by P. J. Palmer, and the work was part of the investigations sponsored by the Development Association and conducted by Prof. S. C. Redshaw at the University of Birmingham. The solution could have been obtained by the use of the mathematical relaxation method or by the experimental soap-film method; but the electrical analogy method, which is really the electrical equivalent of the relaxation process, is simple, rapid and accurate and requires little skill in operation. The electrical potential corresponds to the mathematical stress function. After a brief introduction and an outline of the mathematics of the torsion problem, the report describes the analyser and the operation of the apparatus and then gives a series of test results. These are presented in the form of curves and tables and relate to a number of sections including angle fillets, *T*-junction fillets, single- and double-sided bulbs, and sections and fillets with unequal web thicknesses. For one of the test sections a detailed comparison between the relaxation and analyser solutions is given. The accuracy of the results obtained, about 5 per cent, is discussed, and it is stated that this could be still further improved if a larger number of internal points were used and if the accuracy of the external electrical resistances were higher.

Announcements

WE regret to announce the following deaths:

Sir Henry Clay, warden during 1944–49 of Nuffield College, Oxford, and president in 1929 of Section F (Economics) of the British Association, on July 30, aged seventy-one.

Mr. H. E. Dale, C.B., principal assistant secretary during 1927–35 to the Ministry of Agriculture and Fisheries, author of books on the higher Civil Service in Great Britain, on July 30, aged seventy-eight.

DR. G. W. A. DICK, of the Medical Research Council, National Institute for Medical Research, London, has been appointed to the chair of bacteriology in The Queen's University of Belfast. The following have been appointed lecturers in the University: Colonel D. R. Crone, civil engineering (surveying); and Dr. A. D. E. Pullin, physical chemistry.

THE Association of Agriculture and the Burton Manor Residential College for Adult Education, Burton-in-Wirral, Cheshire, are arranging a course on "Biology and Geography", to be held at the College during August 24–27. One day will be devoted to biological aspects with emphasis on agricultural crops and animal husbandry, and on another the main theme will be geography, in particular the changing pattern of the countryside and the specialized area of dairying districts of Cheshire. There will also be a number of excursions. The course is designed primarily for teachers of rural studies, but should also appeal to all those interested in the countryside. The inclusive fee, including accommodation, is £3 15*s*. Application forms, to be returned by August 18, can be obtained from the General Secretary, Association of Agriculture, 238–240 Abbey House, 2 Victoria Street, London, S.W.1.

RESEARCH AND DEVELOPMENT IN ALUMINIUM

BANBURY LABORATORIES OF ALUMINIUM LABORATORIES LTD.

ALUMINIUM LABORATORIES LTD., a subsidiary of Aluminium Ltd., was formed in 1936 to carry out research, development and exploration for the Aluminium Ltd. group of companies. In 1938 the Banbury Laboratories of the company were built, with the responsibility for research on the problems of fabrication and utilization of aluminium. The Second World War curtailed the activities at Banbury, the laboratories being taken over by the Ministry of Aircraft Production, and another similar laboratory was built at Kingston, Ontario; in 1950 the Arvida, Quebec, laboratory was completed to carry out research in the fields associated with the extraction of the metal. When work at Banbury restarted in 1946, it soon became plain that the accommodation would not be sufficient for the volume of work which was envisaged as a result of the expansion of the aluminium industry during the War. A large programme for extending the premises was therefore drawn up, and these extensions were finally completed in June last. Carried out at a cost of £300,000, they have trebled the floor area, giving a present total of 65,000 sq. ft.

The main features of the extensions are a new two-storied north wing, 345 ft. long, housing laboratories, offices and library, and a single-story experimental block with facilities for structural testing and the building of prototype plant and equipment. Every care has been taken in the design of the new premises, by Sir Percy Thomas and Son, to provide adequate facilities for the varied types of experimental work carried out. For example, the laboratories and offices are heated throughout by radiant ceiling panels to allow full use of the floor space; they are built on a modular principle with movable partitions which can be re-arranged to meet future needs, and all requisite services are built into the laboratory benches. Where necessary, air extraction and forced ventilation are provided, and full air-conditioning is supplied to certain laboratories where control is desirable.

The work carried out at Banbury is of two types—research and service. The service work may be taken to include work in the patents field, or in solving the technical problems of associated companies, or in the wider field of development of uses for aluminium. The research work, although directed principally to industrial needs, includes an important proportion of background work intended to add to the basic store of knowledge about aluminium and thus assist in the solution of future industrial problems.

There are approximately a hundred members of the Research Department, including about thirty-five graduates, divided into four groups; chemists, engineers, metallurgists, and physicists. While each group has its own field of activity, there are many problems requiring co-operative effort, leading to joint work by the groups. Examples of this are lubricating problems in metal deformation, where chemists and engineers work together, and alloy development, which is a problem tackled jointly by physicists and metallurgists. In this short article it may be sufficient to indicate the main interests of the different groups, bearing in mind that similar and complementary work in most of these fields is carried out by the sister laboratory at Kingston, Ontario.

Among the more important researches on which the metallurgists are engaged may be mentioned the study of the continuous casting process, with particular emphasis on the thermal conditions present in the cast shape and their relation to the stresses induced in it. Other metallurgists are working on textural problems such as grain size and the 'earing' of those sheet alloys intended for pressed and drawn parts. In addition, metallurgists and physicists are jointly exploring the application of modern physical metallurgy concepts to alloy formation. In this investigation, as in many others, there is continuing co-operation and discussion with the universities.

The Chemistry Division, while supporting a certain amount of analytical research, has a particularly strong interest in surface chemistry. Work is active on lubrication and, while the engineers are interested in the mechanism of lubrication, the chemists are studying the formulation and chemical behaviour of different mixes, the objects being to solve the problems encountered in the use of cold-rolling lubricants, which sometimes give stains when coiled strip is annealed, and to meet the special requirements for hot-rolling lubricants. Another aspect of the Chemistry Division's work is the investigation of the various surface treatments used on aluminium, such as brightening, anodizing and dyeing, and electroplating. A pilot plant for the study of the processes involved in the milling, filtering and preparation of aluminium paste pigment has also been provided in the new extensions.

In the Engineering Division considerable attention is still being devoted to the problem of metal fatigue, including the behaviour of built-up members and structures, and several useful contributions have been made to the literature of the subject; particular attention has been paid to the development of testing with resonance methods of inducing vibration by the use of the slipping clutch. Work on the mechanism of metal deformation during fabrication and subsequent conversion into end-products is also being carried out. This has as its objectives the improvement of the efficiency of fabricating processes, such as rolling, extrusion and forging, and the establishment of a sound theoretical basis for the forming operations (for example, pressing and deep drawing) of interest to the user. The work of the structural research section is both theoretical and practical, and the equipment includes a test rig in which structures up to 40 ft. long and 7 ft. 6 in. wide can be tested.

The activities of the Physics Division include research on the mechanism of heat transfer and propagation of energy in and through aluminium. The latter has grown out of a war-time interest in the non-destructive testing of sheet ingots and extrusion billets by ultrasonic inspection methods. Research in this direction has continued; several improved techniques are being devised, and fundamental work on the subject has thrown light on phenomena such as the recrystallization of cold-worked aluminium.

The heat-transfer studies are of interest both to the fabricator, in connexion with the heating and cooling of metal, and to the user, in applications where the properties of aluminium as a thermal insulating material are of value. A further important section of the Physics Division is devoted to instrumentation. This not only makes electronic and other equipment for use in the Research Department but also appraises commercial equipment for associated companies.

Although much of the development work on utilization is undertaken by the fabricating companies themselves, problems frequently arise which call for the resources of an industrial laboratory. The Technical Service and Development Department is responsible for dealing with these problems on behalf of associated companies or their customers. The Department has a staff of about forty, including ten graduates. It deals with a variety of day-to-day and long-term problems, the chief of which are metal working and joining, and canning. The welding section, for example, is equipped with a variety of inert-gas shielded arc-welding equipments and is able to give information, advice and instruction on their use. Another important aspect of the Department's work is the development of aluminium containers for the canning of food and beverages. The canning section is engaged on studies of the design, manufacture, use and testing of aluminium cans, and is equipped with pilot plant for carrying out all the operations, from the pressing of the cans to the testing of the canned product.

One of the most prominent features of the extensions is the new library and filing centre, which provides access to technical literature of all kinds, both from its own stocks and by reciprocal arrangement with other libraries.

With the completion of these new extensions, Aluminium Laboratories Ltd., Banbury, is now able to undertake the increasing volume of technical work resulting from the current expansion of the aluminium industry, and in association with its sister laboratories in Canada it is contributing to the solution of many of the fundamental and day-to-day problems encountered in the fabrication and utilization of the metal.

HENRY SALVATORI LABORATORY OF GEOPHYSICS, STANFORD UNIVERSITY, CALIFORNIA

By Prof. JOSHUA L. SOSKE

THE dedication of the Henry Salvatori Laboratory of Geophysics in the School of Mineral Sciences at Stanford University, California, on May 15 marked a significant step in the development of joint industrial-educational efforts to advance the relatively young science of geophysics. The new Laboratory is the gift of Mr. Henry Salvatori and the Western Geophysical Company of Los Angeles, California, of which he is president. It is one of several such major gifts by Mr. Salvatori and his Company to the University, another having been his establishment of the Henry Salvatori associate professorship in geophysics in 1951, which the present writer holds. In speaking at the dedication ceremonies, Mr. Salvatori expressed the conviction that the support thus far given Stanford University in geophysics should be but the beginning of much more widespread support of educational efforts in the discipline. He is a pioneer in geophysics, and is a co-developer of the reflexion seismograph method of prospecting for oil and gas.

The Laboratory is a striking example of the growing tendency of industry in the United States to attempt, through the support of higher education, to achieve two broad goals: first, to discharge its responsibility to education whence most of its trained leaders come, and second, to ensure future growth by encouraging both research and the continued production of highly trained personnel. Economic geophysicists are particularly aware that it is education to which they must look for persons to utilize present techniques, to develop new techniques through research, and to develop administrators of both research and operations within their own organization.

In short, a company engaged in exploratory geophysics is no better than the individuals who operate it; and since the bulk of these persons come from the colleges and universities, it seems quite proper that the company should co-operate in the development of basic research and curricula in geophysical engineering. The generous support of Mr. Salvatori and the Western Geophysical Company indicates their belief that half-measures will not accomplish their purposes.

Basically, the objectives both of the University and of industry are so simple they may be described in two phrases: the development of professional attitudes and the production of graduates in geophysics with professional competence. The first deals with the responsibility of the geophysicist to his employer or client and to the general public welfare. The second deals with the possession of technical knowledge and skills necessary for the geophysicist working in either economic or scientific fields.

In a broader sense, this will require that students of geophysics be subject to at least four distinct areas of education. These areas are listed in the order of exposure which Stanford proposes:

(1) In the School of Humanities the student will secure the training necessary for clear, forceful and productive thinking required in analysing problems and arriving at solutions. Here he will also learn how to express his findings effectively in both written and oral form.

(2) In the Department of Mathematics the student will become familiar not only with techniques but also with deductive reasoning, logic and precision.

(3) The third area consists of the fundamental sciences, such as geology, physics, chemistry, electronics and general engineering principles. Emphasis is to be placed upon the particular subject most directly concerned with the branch of geophysics chosen by the student. At Stanford University the geophysics student is particularly fortunate in the strength of the faculties in these related fields.

(4) The fourth area involves both the general and specialized training in exploratory geophysics. A curriculum has been designed with sufficient flexibility to provide the orientation necessary for both the physics-inclined and the geology-inclined students.

In summary, these are the objectives of the planned programme of the Division of Geophysics at Stanford, in the order of their importance:

(1) The primary purpose is to provide theoretical and practical training for engineers and scientists in the field of geophysics. During instruction, emphasis

is placed upon the requirements for exploration geophysicists by basic industries, educational institutions and government agencies. The world's basic industries alone employed 1,100 geophysical parties full-time during 1953, at an approximate cost of 400,000,000 dollars. The importance of this activity is plainly evident in the fact that half the known oil reserves of the United States have been discovered with the aid of geophysical techniques. Yet it is estimated that fewer than two hundred students trained in this science graduated from colleges and universities of the United States in 1953. This places the present supply of geophysicists completely out of proportion to the demand.

(2) The second purpose is to make available to students in all branches of the School of Mineral Sciences at Stanford University the opportunity of becoming familiar with the fundamental concepts of modern methods of geophysical prospecting. The wide acceptance of the techniques of applied geophysics as an important tool of the exploration geologist suggests the necessity that at least an elementary understanding of them be made a part of the education of every geologist.

(3) The third objective is to encourage and to carry on creative research in geophysical exploration methods. The Salvatori Laboratory provides facilities which will permit this research, both pure and applied. There is abundant opportunity for interested individuals and commercial firms to aid in the acceleration of this search for basic knowledge so important to the future of geophysics.

EXPERIMENTS ON ARTIFICIAL STIMULATION OF RAIN IN EAST AFRICA

By D. A. DAVIES

Director, East African Meteorological Department

IN previous communications[1,2], descriptions were given of experiments on the artificial stimulation of rainfall carried out in 1951 and 1952 at Kongwa, Tanganyika. The results of these experiments have been published as Memoirs of the East African Meteorological Department[3,4]. Two further series of experiments in East Africa can now be described; a full report is in preparation.

The seeding agent used throughout was finely ground hygroscopic salt (mainly common salt) and the method of seeding was the hydrogen-balloon method already described[2].

In the earlier experiments the analysis of the results was based on the readings of the close grid of rain-gauges which covered the area. This method has the advantage of being entirely objective. In the two series of experiments under consideration it was not possible, for a number of reasons, to install a similar grid of rain-gauges, and the results of the experiments are based on the personal observations of the field-officer conducting the experiments. In most cases this officer was a meteorological assistant of the East African Meteorological Department chosen for his exceptional competence in meteorological observational work, and who was given special training for this work. For short periods scientific officers of the Meteorological Department were present and, on some occasions, officers of other Government departments conducted experiments after having received necessary instruction. As will be seen later, there is remarkable consistency between the results obtained by all observers.

The first series of experiments was conducted at Amboseli in southern Kenya during the period October 18–December 12, 1953. Balloons were released whenever large cumulus clouds were present. The aim was to release up to five balloons into each cloud, each balloon carrying about 15 gm. of finely ground hygroscopic particles. Dispersal of the particles was effected by the explosion of a small charge of gunpowder, ignited by a time-fuse. The length of the time-fuse was adjusted to cause dispersion just above the base of the cloud. On days when no large cumulus clouds appeared, no experiments were conducted.

During the period of 56 days, seeding took place on 25 days and the total number of cloud seedings was 29. On five occasions the balloons missed the target cloud, leaving 24 occasions of useful experiments. On 19 of the 24 occasions, rain was observed to fall from the seeded cloud. The rain was described as light or very light on 16 of the 19 occasions; moderate on two occasions; and heavy on one occasion. On four of the occasions when the rain was described as very light, it evaporated before reaching the ground. The interval between the explosion and the observance of rain ranged from 16 to 38 min. (mean 26 min.), and the duration of the rain from 3 to 55 min. (mean 15 min.).

The five occasions out of the 24 on which rain did not follow the explosions are of interest. On four of these occasions rain was falling from the cloud before the explosion took place and in all four cases the rain was reported to have decreased in intensity shortly after (7–30 min.) the explosion, but later to have become more intense again. On one occasion there was a temporary cessation of rainfall. On the remaining occasion two balloons were released into a large cumulus which broke up after 20 min.

On the five occasions that the balloons missed the target cloud they entered smaller clouds on four occasions, and in all cases the clouds were reported as having dispersed. On the fifth occasion the balloon exploded in mid-air and a small cloud was seen to form in the vicinity shortly afterwards.

The experiments so far referred to were all conducted by staff of the East African Meteorological Department. During the same period, seven experiments were carried out in an adjacent region near Kajiado by a European game ranger, who states that the experiments "took place on days when the whole visible horizon was free from rain squalls, so prevalent at this time of year, and were finally halted with the advent of the 'short' rains in the District". The clouds chosen for seeding were generally large cumulus clouds, but on one occasion the sky was completely overcast and the clouds may have been thick strato-cumulus (possibly with cumulus embedded). The results reported by the game ranger were that on five of the seven occasions rain was observed to fall from the seeded cloud between 15 and 30 min. after the explosion of the charges; on one of these occasions the rain was reported as not reaching the ground. No results were obtained on the other two occasions. The falls of rain were again generally light; but on one occasion a heavy storm developed.

Turning now to the second of the experiments, these were conducted at Dodoma, in Tanganyika, during the period January 3–March 31, 1954. The procedure regarding the selection of clouds on which to experiment was essentially the same as for the earlier experiments described above.

During the period of 88 days, seeding took place on 36 days and the total number of seedings was 44. On 11 occasions the balloons missed the target cloud, or the target cloud had started to disperse before the explosion took place, leaving 33 occasions of useful experiments. On 23 of the 33 occasions, rain was observed to fall from the seeded cloud. The rain was described as light or very light on 20 of the 23 occasions; moderate on one occasion; and heavy on two occasions. On five of these occasions when the rain was described as light or very light, it was reported as evaporating before reaching the ground. The interval between the explosion and the observance of rain ranged from 13 to 35 min. (mean 23 min.), and the duration of the rain from 4 to 28 min. (mean 14 min.); but on one occasion rain was reported as recommencing shortly after the first shower and lasting several hours.

On 10 occasions out of 33 on which rain did not follow seeding, or if it occurred was unlikely to be due to seeding, are of interest. On one of these rain was already falling from the cloud before the explosion, and on this occasion the rain ceased 10 min. later. On another occasion there was rain which by virtue of the wind direction was probably not connected with the experiment. On a third occasion there was rain from the target cloud; but the close proximity of other precipitating clouds makes it doubtful whether the seeding had caused the rain. On the remaining seven occasions the cloud was observed to break up and disperse.

Of the 11 occasions (out of the total of 44) on which for various reasons no rain stimulation was to be expected, two resulted in the dispersal of a small cloud which was not the target cloud, four resulted in the accelerated dispersal of the target cloud which was already dispersing, one did not appear to expedite the dispersal of an already dispersing cloud, three exploded in clear air because the target cloud had vanished, and one did not produce an explosion, presumably because the fuse was extinguished.

The Dodoma experiments just described were carried out by staff of the Meteorological Department. Another series of similar experiments was, however, carried out at Dodoma in December 1953 by a European government officer. The full report from this officer has been delayed by sickness and is still awaited; but in discussion he stated that light rain occurred on most occasions 20–40 min. after the explosion.

On several occasions, in both the main series of experiments, changes in the colour of the cloud were reported in the vicinity of the explosion. In most cases dark grey turned temporarily to patches of light grey; on a few occasions brown patches or streaks were reported.

An analysis of the effect of the number of balloons used shows that in almost all cases when three or more charges were released into the cloud, rainfall was afterwards observed; in most cases where one was released the clouds were small and dispersal followed. The significance of this should not be overestimated, since there was a natural tendency for fewer balloons to be released when chances of successful stimulation seemed less. For example, if after the first balloon or second balloon had been released the cloud showed sign of dispersing, no further balloons were released.

With regard to the five occasions when the balloon entered a cloud from which rain was already falling, the seeding of these clouds was in all but one occasion intentional, the aim being to determine the effects of seeding on such clouds. On that occasion the balloon missed the target cloud and entered the rain cloud.

In assessing the significance of these experiments it is important to bear in mind the limitations of the method of observing the results which had perforce to be adopted. This method consisted essentially of visual observation, by the officer conducting the experiments, with the assistance of binoculars. The readings from a sparse network of rain-gauges were also available in both series of experiments and were of some assistance. Within these limitations every possible care was taken. The time of release of each balloon, the time of explosion, the time of commencement and the duration of rain downwind from the point of release of the balloon and the distance and azimuth of the point of first occurrence of the rain were all carefully recorded. Details of the observed changes in the seeded cloud and the apparent intensity of the rain were also recorded, together with any other information which seemed relevant. Surface and upper winds were measured by pilot balloons.

Having regard to all these considerations, it is thought that the figures quoted above for the frequency of observed rainfall following the seeding are adequate to justify the conclusion that the cloud seeding did stimulate rainfall on the majority of occasions, but that such rainfall was generally very light or light. This conclusion tends to be supported by the fact that the results show several points of similarity with those of the earlier experiments at Kongwa in 1952, which were carried out using the same technique but with a different method of assessing results.

In the 1952 Kongwa experiments there was an increase in total rainfall on days of seeding at a distance downwind from the fixed point of release of the seeding agent corresponding to a time interval of about 30 min. On some occasions at Kongwa, seeding resulted in dispersion of small cumulus clouds. In addition, the Kongwa experiments suggested "that the introduction of such (hygroscopic) particles into large cumulus clouds may produce an immediate interference with the rain-producing processes in such clouds, and that this effect might result in a reduction of rain in the immediate vicinity". All these points seem consistent with later experiments.

The theoretical interpretation of the experiments will be discussed in the report being prepared; but it may be said that, making reasonable assumptions regarding certain cloud parameters, the theoretical time of occurrence of the rain based, for example, on Bowen's collision process theory[3] shows reasonable agreement with the observed values. If it is assumed that the average cloud-droplet diameter is 20 μ, the liquid water content 1 gm./m.^{3}, the upward air velocity 1 m./sec. and the initial diameter of the drops formed by the hygroscopic particles 100 μ, then the time at which rain should appear from the base of the cloud is about 22 min. The amounts of rain which fell on some occasions are, however, too great to be accounted for by Bowen's theory unless the assumptions regarding the cloud parameters are seriously in error. The assumed value of 1 m./sec. for the vertical velocity of the rising air current in the cloud may well be too low in certain cases, and this would have a significant effect on the amount of rain resulting. Alternatively or additionally, a chain reaction due to breaking up of drops[6] and/or a turbulence effect[7] may have been operative, neither of which is provided for in Bowen's theory.

It is hoped to conduct further experiments this year using similar techniques. In these experiments it is proposed that the particle size of the hygroscopic substance shall be reduced to about 20 μ diameter, with the object of producing water drops in the cloud initially of about 50 μ diameter. The particle size hitherto used has been mainly between 50 μ and 75 μ, which results in water drops at least 100 μ diameter. This revised procedure should result in more rain being produced, but after a longer time interval.

DUTCH–NORWEGIAN JOINT ESTABLISHMENT FOR NUCLEAR ENERGY RESEARCH

REPORT FOR THE YEAR 1952–53

THE Joint Establishment for Nuclear Energy Research (JENER), which was set up in April 1951 jointly by the Netherlands and Norway for the purpose of carrying out research and development work in the field of atomic energy, is supported financially by the governments of the two countries and by private industry. The Establishment is governed by a joint commission consisting of three representatives from the Netherlands and three from Norway and is directed by Mr. Gunnar Randers. The organization's research establishment and laboratories are situated at Kjeller, fifteen miles north-east of Oslo, Norway, and include the heavy-water-moderated uranium reactor, Joint Establishment Experimental Pile (JEEP), which is now in continuous operation. The second annual report of the Establishment, which has now been published*, gives full details of the progress made during 1952–53.

The factual report is preceded by the text of the opening address which Mr. Randers delivered at the international conference on heavy-water reactors held at Kjeller and Oslo during August 11–13, 1953, and by a short descriptive article on recent developments in radioisotope production and application in Norway. In his address, Mr. Randers explained that the main purpose of the conference was to hear the opinions of scientific workers as to the possibilities and difficulties of the particular approach adopted by Norway to the study of atomic energy, namely, by working exclusively with heavy-water reactors and natural uranium. It is not known whether reactors with natural uranium are practical for use in industry; but Mr. Randers asserted that, so far during the work at the Establishment, nothing has been found to rule out the possibility. The cost of fuel in a natural uranium reactor is approximately the same as in an enriched reactor; but the extremely high cost of heavy water presents a real problem for the future of heavy-water reactors. Mr. Randers outlined his reasons for the selection of a heterogeneous reactor—that is, one with uranium rods in heavy water—and pointed out that in such a reactor 1 per cent of the uranium could be burnt. He said that at Kjeller they are considering the construction of a heterogeneous heavy-water reactor to produce up to 25,000 kW. This reactor would use 10 tons of uranium, be cooled by heavy water at a temperature slightly above 200° C. and at a pressure of 35 atmospheres, and be moderated by heavy water at approximately 60° C. Attached to the boiler there would be a saturated steam turbine of about 25 per cent efficiency. The insulating material between the hot circulating heavy water and the cooler moderator might be beryllium oxide. It was hoped that the money for the venture would be forthcoming, but in the meantime considerable progress is being made with the design of the reactor.

The annual report mentions that since September 1952 JEEP has been in almost round-the-clock operation for five days a week—during ordinary staff working-hours for experimental work by the scientific staff, and at other times at maximum power-level for isotope production. In order to compensate for the heavy load of isotope material, two additional fuel rods, making a total of sixty-four, have been inserted in the reactor. The shielding has also been improved, and a mechanical system for extracting fuel rods has been constructed in addition to a storage cell for hot rods. Methods of visual inspection of the rods and of the inside of the reactor have been developed, and a permanent unit for recombination of dissociated heavy water built and installed. The extraction of heat from the reactor takes place in two stages, first from the heavy water to ordinary water and then from the ordinary water to free air. The hot air was originally discharged into the atmosphere, but now the heat from the air has been harnessed and utilized to heat the reactor hall. The extension to the reactor building to house new laboratories and offices was due for completion in September last.

Steady progress has been maintained with the equipping of the chemical laboratory, and an adequate staff has now been built up. The spectrographic laboratory is fully equipped, and some metallurgical research has been commenced. The constant surveillance of the heavy water in the reactor and some preliminary research work in transuranium chemistry are two of the main activities of the Chemistry Department which are specifically referred to in the annual report.

Work in the Physics Department has been directed more and more towards pile neutron physics, and the Kjeller reactor has proved to be a useful tool for physics research. The equipment and facilities available for neutron spectroscopy and neutron diffraction are described and illustrated in the report, in addition to the pile oscillator, gamma spectrograph, pulse height analyser, beta spectrometer and mass spectrometers. For the routine production of radioisotopes, resulting in a hundred and forty isotope shipments and service irradiations for customers outside the Establishment, and ninety-seven for the use of the Establishment's own staff, the reactor has been operated at an energy-level giving 1–5 × 10^{11} neutrons/cm.^{2}/sec. thermal neutron flux in the isotope channels and about eighty hours of effective irradiation time per week. Deliveries of carrier-free iodine-131 commenced in February 1953, and radioactive gold was expected to be ready for production by the end of the year. The preparation of organic compounds labelled with carbon-14 has been continued, and some fifteen compounds are now available. In the autumn of 1952 a regular consultative service was started by the Isotope Department for Norwegian industry, and details of the various industrial firms and the investigations undertaken with the particular isotopes used are listed in the annual report.

---

* Joint Establishment for Nuclear Energy Research. Second Annual Report, 1952/53. Pp. iv+41. (Blindern, Oslo: Akademisk Trykningssentral, 1953.)

The final sections of the report deal briefly with reactor development; health physics; the information service and its publications; the accounts of the Establishment for the period July 1, 1952–June 30, 1953; the personnel in the various departments; and the various scientific meetings and conferences attended by members of the staff of the Establishment during the period under review.

BRITISH HYDROMECHANICS RESEARCH ASSOCIATION

ANNUAL REPORT FOR 1952–53

THE sixth annual report of the British Hydromechanics Research Association, covering the period October 1952–September 1953[*], records satisfactory development in both the activities and finances of the Association. Although the scale of operation is modest, it is stated that the Association's technical prestige has risen considerably and that it is being consulted as an authority on fluid mechanics by a widening range of industries.

The first five-year period of government grant-aid expired at the end of the year under review, and an application for its continuation and augmentation submitted to the Industrial Grants Committee was received sympathetically. However, the new grant, although rising to a higher maximum than the original, is not so favourably proportioned; for the first £18,000 of income the grant is £9,000 and then £75 per £100 up to a maximum additional grant of £9,000. It is expected that subscriptions from present members for 1953–54 will exceed the minimum grant-earning figure.

The two visitors to the Association, Brigadier R. A. Bagnold and Prof. L. Rosenhead, appointed by the Department of Scientific and Industrial Research, continued to take a keen interest in the activities of the Association and to attend meetings of the Council and research committees. During the year the constitution of these committees was revised, and those formerly dealing with fundamental fluid mechanics, instruments, and pipe-flow problems were combined into a single committee dealing with non-machinery problems, while the other research committees were enlarged. Details of these committees, together with a list of their members, and of the ordinary and associate members of the Association, are given in the report.

The staff of the Association has been increased and now numbers thirty-three, the senior staff consisting of the director of research, Mr. L. E. Prosser; the deputy director of research, Mr. R. C. Worster; five research engineers and one junior research engineer; the secretary and the librarian. From the research work undertaken since the Association's laboratory was opened in 1951, much useful information has emerged, particularly in relation to sump design, pulsating flow metering, pre-rotation in centrifugal pumps and the precision manometer. Some of the more recent work and of the results obtained are briefly described in the annual report. Instruments for the metering of pulsating flows have been successfully developed, and preliminary work with simple suction-pump layouts has been extended to models of actual or proposed installations. The collection and study of data on the friction loss in pipes and fittings have now been completed. A technical note dealing with the pressure surges resulting from a failure of the power supply to a pumping set has recently been published and, as little information is available on the subject, work has been started on an investigation of the rate of gas release from liquids when the pressure is reduced.

There is considerable interest in the hydraulic transport of large coal, and the Association has accordingly undertaken an extensive investigation of the basic hydraulic process involved. The results obtained so far indicate that the hydraulic transport of coal on a large scale should be economic over distances of several miles. A promising application is the vertical transport of coal from the pit bottom or working face to the surface, and the main practical problem of raising the mixture of coal and water to the required pressure is being tackled by the development of a coal feeder for delivering the coal into a pipeline where the water has previously been raised to high pressure by conventional means.

Fuller information about the various investigations can be obtained from the numerous technical notes, research reports and published papers of the research staff of the Association, a complete list of which is included in the annual report.

INSTITUTE OF PHYSICS

ANNUAL REPORT FOR 1953

THE thirty-fourth annual report of the Board of the Institute of Physics, covering the work of the Institute during 1953 (obtainable from the Institute at 47 Belgrave Square, London, S.W.1), records that the Board of the Institute met six times, and its various standing committees twenty-four times, during the year. The membership increased by 248 to 4,595. Applications for election or transfer to the various grades of membership of the Institute received during 1953 numbered 581, compared with 651 in the previous year. The degrees of a further four universities, in particular the newly established degree in applied physics of the University of Manchester and the associateship in applied physics of the Royal Technical College, Glasgow, were recognized by the Board, and two technical colleges which had applied for extension of recognition were visited by representatives of the membership and examinations committee. Seven of the thirty-two candidates for the graduateship grade of membership of the Institute were successful; for the National Certificates in applied physics the numbers of candidates continued to increase, being 151 candidates for the ordinary level and 55 for the higher certificate, compared with 137 and 33, respectively, in 1952.

---

[*] British Hydromechanics Research Association. Sixth Annual Report, October 1952 to September 1953. Pp. 26. (From the Association, Nettleswell Road, Harlow, Essex.)

The circulation of the Institute's two journals, the *Journal of Scientific Instruments* and the *British Journal of Applied Physics*, increased during the year, and there was a further improvement in the advertisement revenue. The last three monthly issues of the 1953 volume of the *Journal of Scientific Instruments* were enlarged in order to reduce the delay in publication of original contributions, and provision has also been made for similar enlargement of the *British Journal of Applied Physics* during 1954 both to reduce delay in publication and to extend the scope of the *Journal*. The twelve issues of the Institute's *Bulletin* (issued to members only) included summaries of some of the meetings of the Education Group, the Board's reports on "Problems concerning the Education of Physicists" (afterwards re-issued as a pamphlet) and on "Summary of Salaries and Enrolments", in addition to a number of important articles based mainly on lectures delivered at meetings of the Institute. In the "Physics in Industry" series, a new volume entitled "Modern Mass Spectrometry", by Dr. G. P. Barnard, was published during the year, and the first four booklets in the new "Monographs for Students" series were issued.

The second convention of the Institute, held in Bournemouth during May 27–30, was attended by approximately 450 members and their ladies and guests; its agenda included the thirty-third annual general meeting of the Institute, a discussion on the education of physicists and twelve group meetings, at which twenty-three papers were read. Lectures were given by Sir John Cockcroft on recent advances in nuclear physics[1] and by Dr. A. C. Menzies on recent developments in applied optics[2], and Canon C. E. Raven gave an evening address on the impact of physics on science and religion[3].

The Institute has seven branches in Great Britain, an Indian branch under the chairmanship of Sir C. V. Raman and an autonomous Australian branch with divisions in different States. In addition to the branches in Great Britain, there are seven specialist subject groups—electronics, electron microscopy, industrial radiology, industrial spectroscopy, stress analysis, X-ray analysis and education—which arrange their own programmes of scientific meetings and conferences. Seven specialist conferences were held by the various branches and groups, including a two-day meeting of the Industrial Radiology Group jointly with the Hospital Physicists' Association, and a conference of the X-Ray Analysis Group on film methods and microdensitometry and on identification by X-ray analysis. As in previous years, the Institute collaborated with the University of Bristol in a summer school and conference, held at Bristol during July 13–16, on the theory of the plastic deformation of metals, and it was also associated with a conference organized by the Clarendon Laboratory, Oxford, and held there during July 18–23, on the subject of ionization phenomena in discharges. The proceedings of the conference on "Static Electrification" which was held by the Institute at Bedford College, London, during March 25–27, have been separately published[4].

The Institute has been represented on many joint committees and bodies, including committees of the British Standards Institution, the Royal Society and the Parliamentary and Scientific Committee, and further details are given in the annual report. The Faraday Society, the Royal Meteorological Society and the British Institute of Radiology, which together with the Physical Society form the four participating societies of the Institute, have given notice of withdrawal from participation in accordance with the provisions existing in the constitution. The Physical Society is in a different position from the other three societies since its members are physicists, and will continue to have two seats on the Board of the Institute. In order to encourage members to support *Science Abstracts* and to enable them to continue to enjoy the privilege of purchasing copies of both *Physics Abstracts* and *Electrical Engineering Abstracts* at reduced rates in spite of increased costs of production, the Board has agreed to make a modest annual basic payment to the management committee of the abstracts from its publications account, and the Institute in return will be represented on the management committee.

This year the thirty-fourth annual general meeting of the Institute was held at the Institute's house in London on May 18, when the following were elected to take office on October 1: *President*, Sir John Cockcroft; *Vice-President*, Mr. G. R. Noakes; *Honorary Treasurer*, Dr. S. Whitehead; *Honorary Secretary*, Dr. B. P. Dudding; *New Ordinary Members of the Board*, Dr. K. A. G. Mendelssohn and Mr. H. P. Rooksby. Prof. W. E. Curtis and Dr. C. Sykes (past-presidents), Mr. O. W. Humphreys, Dr. T. L. Ibbs and Prof. F. A. Vick (vice-presidents), Dr. H. Barrell, Dr. N. A. de Bruyne, Dr. P. H. S. Henry, Mr. A. T. Pickles, Dr. W. H. Taylor and Mr. R. G. Wood continue to serve on the Board.

FORESTRY IN BRITISH HONDURAS

ANNUAL REPORT FOR 1952

THE annual report for 1952 of the Forest Department of British Honduras*, whence came the mahogany so well known in Britain during the nineteenth century, states that the Department reached thirty years of age in April 1952. The report furnishes abundant evidence of the vacillation of the authorities concerned as to the value of the Department and of the forests to the Colony. "Because of staff shortages and changes," says the report, "it was impossible to issue Forest Department Annual Reports for the years 1950 and 1951."

The Department's difficulties are mainly due to staff shortages. The post of conservator was vacant throughout the year, and two officers acted in the post. There were apparently three gazetted officers only on the staff at the end of 1952 (one on leave and one newly joined). It is scarcely surprising to read that the forest boundaries are overgrown and require reclearing and that the forest estate is at present inadequate and is also insufficiently secure: during 1952 the lease of large areas of land in the forest reserves to the Colonial Development Corporation for agricultural purposes was being negotiated. If this is the case, the legal position of the so-called forest reserves is obviously very unstable.

Finally, as can be well understood, no working plans are in force. Yet at its commencement the Department started under the most promising auspices: it was tentatively created for two years, and three technically trained forest officers were appointed. The fourth annual report of the then young Department (it had passed the two-year ordeal successfully) was issued in 1926 and was reviewed in *Nature* (119, 256; 1927). The following extract from this review merits reproducing: ". . . it is easy to see that the young department has already made good. So far, the work has been mainly devoted to assisting the several lumbering companies at work in the forests on government leases. In some respects the operations are proceeding on lines similar to the working of the Burmese forests by the British forest officers of earlier days. Obviously, however, the work of exploring the government forests, collecting topographical and other details, has been commenced (the superior staff now amounting to six), and it is hoped to be able to carry out the exploration of the practically unknown territory of the Western Highlands. . . . At the time of writing, a reliable base-line has been established between Vaca and the Rio Grande and a good general idea of the forests of this region obtained". That was twenty-seven years ago. The extracts from the present report already given indicate the history of the Forest Department since then and the ignorance on the part of the authorities of the value of the forest estate to the people and the Colony itself.

---

E. P. STEBBING

CAMBRIDGE UNIVERSITY EDUCATIONAL FILM COUNCIL

THE seventh annual report of the Cambridge University Educational Film Council states that Prof. J. F. Baker has succeeded Sir Lawrence Bragg as president and that two new vice-presidents, Mr. S. C. Roberts, master of Pembroke College, and Prof. J. A. Steers, head of the Department of Geography, have been appointed. With the use of a Merlin Gerin camera in the Department of Engineering, a number of 16-mm. ciné pictures at 4,000 frames per second of tensile specimens being broken have been obtained. Some medium-speed pictures, at 100 frames per second, of the operation of a new testing machine have been taken; cinematography is also being used in connexion with the flow of gases in internal combustion engines. Members of the Departments of Anatomy and of Physiology have collaborated in the making of a film, "The Behaviour of Dissociated Sponge Cells". The use of films in teaching has been maintained especially in the University Faculties and Departments of Anatomy, Archæology and Anthropology, Economics and Politics, Engineering, Geography, Slavonic Studies and Zoology. In the Department of Education lectures on the use of visual aids continue as a regular part of the course. In a continuation of the film sessions for students of history, the films "Peter the Great", "Kameradschaft", "Day of Wrath", "Ivan the Terrible", "Journey into History", "Images Gothiques" and "Ange de la Paix" have been shown. The purchase of some 16-mm. editing apparatus has improved film-making facilities in the University. There remains, however, the need for a central cutting room, and an arrangement by which films may be processed within the University.

A proposal discussed between the Film Council and a member of the B.B.C. Television Service may greatly assist the making of films in the University. Film-making facilities would be provided, and also a copy of any film used, in return for the provision of suitable science subjects for television programmes. The Film Council again urges that all the films made in Cambridge by the late Sir Joseph Barcroft should be traced and catalogued, and, where necessary, edited, copied and preserved. The Council has also recommended further Cambridge films for inclusion in the Scientific Film Library. Projection arrangements are much as they were a year ago, and there is still a lack of continuous 35-mm. projection facilities in the University.

EVIDENCE OF FIRE IN SOUTH AFRICAN CAVE DEPOSITS

DR. KENNETH P. OAKLEY

British Museum (Natural History)

IN 1947 great interest was aroused by Prof. Raymond Dart's announcement that evidence had been found at the Limeworks in the Makapansgat Valley, Central Transvaal, that *Australopithecus* was a user of fire. He based this conclusion on Dr. V. L. Bosazza's identification of fragments of a brown glass-like substance in the basal grey beds there which had yielded remains of this hominid. The vitreous material was regarded as having resulted from the action of fire in the presence of lime, phosphates and ash[1].

Some anthropologists have doubted these conclusions. There is no evidence that *Australopithecus* was a tool-maker, and on general grounds it appears most unlikely that the use of fire preceded the manufacture of tools. Moreover, three other possible explanations of the vitreous material in the Makapan deposit might be advanced: although siliceous and vitreous in appearance, it may have been produced by some chemical action not requiring a high temperature; even if the material is true glass, it may have been due to fires ignited by men living contemporaneously with *Australopithecus*; or it may have been produced by fires ignited at the mouth of the cave by some natural conflagration.

The second possibility certainly has to be taken more seriously now that there is evidence indicating that tool-making hominids (that is, 'men' in common parlance) were living contemporaneously with Australopithecines in South Africa[2]. The idea that the vitreous material possibly originated through a natural conflagration might seem more far-fetched; but quite recently evidence has come from the Cave of Hearths, farther up the Makapansgat Valley, which shows that this, too, is at least a plausible hypothesis.

Through the courtesy of Prof. C. van Riet Lowe, I had an opportunity in March 1953 of visiting the Makapan sites in company with him and with Prof. and Mrs. Dart. At the Cave of Hearths, I was much impressed by the thickness (more than 4 ft.) of what appeared to be cindery ash forming the so-called basal hearth in the Upper Acheulean zone of the cultural sequence. This 'hearth' is generally regarded as the oldest proved evidence of the use of fire by Stone Age man in Africa. I was, however, puzzled by two features of the ash: (1) it appeared to contain no fragments of charcoal or burnt bone; (2) it rested directly on a clean surface of stalagmitic dripstone. Dripstone is normally formed only in the interior of caves, not where they open as rock-shelters. On the other hand, men do not regularly light fires in the deep recesses of caves, but as a general rule only at their openings. Yet if there had been any appreciable time-interval between the accumulation of the dripstone in this cave and its conversion into an open rock-shelter, say, by cliff falls or denudation, one would expect to find that some soil or rock debris had collected on the surface of the dripstone before men began burning fires on it. There was no trace of such material below the 'hearth'.

Excavations at the Cave of Hearths carried out between June and October 1953 by Mr. Revil Mason, under the general direction of Prof. van Riet Lowe[3], revealed hearths at ten levels in the 30 ft. of deposits overlying the 'basal hearth', ranging in age from Fauresmith (Earlier Stone Age III), through five stages of Middle Stone Age culture, to the Late Stone Age. Samples of all the main hearths have been sent to London for carbon-14 age-determination at the British Museum Research Laboratory. (A few have been forwarded to Prof. W. F. Libby at the Institute of Nuclear Studies, Chicago, who has reported that a hearth sample of Middle Stone Age IV showed an age of 15,100 ± 730 years.) In order to check whether the samples submitted contained adequate quantities of carbon, pilot fractions of them were assayed by Miss P. Hammond and Mr. A. E. Rixon in the Palæontological Laboratory of the British Museum (Natural History). The results were as follows:

Hearth level	Weight of sample (gm.)	Percentage of free carbon
Late Stone Age	819	7·7
Middle Stone Age V	1,106	8·5
" " IV	256	4·9
" " III	240	8·7
" " II	282	8·3
" " I	408	7·6
Earlier Stone Age IV	261	4·1
" " III	203	8·7
Basal hearth (E S.A.I.)	338	0·0

The absence of carbon from the pilot fraction of the basal-hearth sample was so unexpected that two additional pilot fractions of the basal-hearth sample were tested; but in neither was any trace of free carbon found. Another sample of the same deposit, collected independently by me in March 1953, was also tested, and likewise proved to contain no free carbon.

The discovery that samples of the 'basal hearth' were devoid of free carbon suggested to me, in the light of my field observations, that the deposit was not wood-ash as had been assumed, but that it might be calcined bat-guano. I therefore asked Mr. Rixon to test the phosphate content of the samples; and he reported that they were in fact largely phosphatic (averaging more than 20 per cent P_2O_5, compared with 15 per cent in a sample of experimentally calcined bat-guano and 2 per cent in an overlying undoubted hearth). A further test showed that the material contained sufficient oxides of iron to account for its colour (dark grey with yellowish streaks).

When the basal-hearth deposit was first encountered in 1937 (a thickness of only a few inches was then exposed), Prof. van Riet Lowe submitted a sample to the Director of the Geological Survey of South Africa, who reported that it contained some free carbon, and in its harder parts some glassy slag-like material[4]. Thus it may well be that the deposit is composite, and that in its upper half, and where it thins out at the margins, there is possibly some admixture with the ashes of the first fires lit by Late Acheulean man. Indeed, Prof. Lowe has told me that two stone hand-axes have been found in the loosely consolidated deposit, one 2 ft. below its surface, and that both appear to be fire-pitted.

The conclusion that the bulk of the basal-hearth deposit is calcined bat-guano might suggest simply that Stone Age man used this material as fuel. Maybe he did; but nevertheless the fact that the deposit in question is devoid of charred bones and rests directly on a clean surface of stalagmite strongly indicates that here it is a natural, mainly undisturbed, accumulation which was adventitiously burnt.

Bat-guano commonly accumulates on the floors of the interiors of caves, and it is not at all unusual to find a deposit of this material resting directly on a dripstone formed when the cave was wetter. If bat-guano had accumulated on dripstone in the original Cave of Hearths, and then a cliff fall opened up the cave so that it became a convenient rock-shelter for human habitation, it is quite possible that the first fires to be lighted by man would have been placed on top of dried bat-guano. The guano of insectivorous bats, consisting largely of insect wings and elytra, is very inflammable. (In the middle of the past century, a hunter is said to have attempted to smoke a bear out of a cave in Blanco County, Texas, by igniting the bat-guano. The result was an explosion, after which the deposit continued to burn for two years[5].) In the circumstances which I have postulated, the guano would have caught fire, and aided by a through draught it would have become in time completely calcined; draughts are common in these caves, as Piet Potgieter's men learnt to their dismay when they tried to smoke out the Makapan tribesmen from the historic cave in this same valley a century ago.

If the brown glass-like fragments found by Bosazza in the *Australopithecus* deposit at the Makapansgat Limeworks were in fact produced by the fusion of sandy cave-earth, one has to allow the possibility that it was brought about by the burning of bat-guano ignited at the cave entrance by a natural grass fire. Dr. Desmond Clark has described to me how on an occasion when he was working in the Mumbwa Caves in Northern Rhodesia a grass fire reached the mouth of one of them and, drawn by a through draught, roared in for a few minutes as if in a furnace. In such circumstances the ignition of bat-guano and local fusion of intermixed sand would be by no means inconceivable.

THE AUSTRALOPITHECINE OCCIPUT

In a recently published essay[1], Prof. S. Zuckerman has discussed at some length the evolutionary position of the australopithecines under the thre headings of evidence relating to: (1) the brain, (2) th face and teeth, and (3) upright posture. The first tw sections are dismissed after very brief discussion, th main subject of the essay being a discussion of evidenc relating to posture. Under this heading the author is chiefly concerned with the nature of the occipital region of the skull and the pelvis. After much discussion and speculation, Zuckerman comes to the conclusion that the Swartkrans prehominid must have had a "powerful and shelf-like" nuchal crest because it had a sagittal crest. He further concludes that it "carried its head on its vertebral column far more in the manner of a gorilla than of a man".

There is, however, direct evidence on the presence or not of a nuchal crest in the known australopithecine material. One of the relevant specimens is the occipital fragment of a calvarium from Makapan described by Dart[2]. This specimen consists of the greater part of the occiput, as well as a good deal of the parietal bones, of an adult. On the original, which is very well preserved, the areas of attachment of the temporal and nuchal muscle masses are plainly visible. The temporal muscles clearly did not actually touch the nuchal musculature. The temporal lines are very widely separated posteriorly but converge as they pass forward, so that they are practically in contact in the midline at the point where the specimen is broken. This point is well behind the vertex—a fact which is easily proved by comparing the specimen with the complete skull from Sterkfontein, which belongs to the same species[3]. The superior nuchal line and the temporal lines thus enclose a relatively large, roughly triangular, area which was not covered by temporal or nuchal muscles. From other specimens from Swartkrans and Sterkfontein, it is abundantly clear that in the australopithecines the temporal lines approach each other most closely in the general region of the bregma or just posterior to it. Anteriorly and posteriorly of this region they diverge fairly sharply. It is therefore manifest that the temporal lines of the Makapan occipital fragment, which are already almost touching well behind the vertex, must have fused farther forward—hence there must have been a sagittal crest. There is, however, no 'shelf-like' nuchal crest. Instead there is only a slightly thickened ridge of bone, marking the position of the superior nuchal line, which is no more strongly developed than that commonly encountered in modern euhominids.

A second specimen which yields direct evidence on this point is *SK* 48 from Swartkrans. This had a well-developed sagittal crest; but only that part of it near the bregma is present, the remainder having been lost in the course of recovering the specimen. This specimen is one of the two referred to by Zuckerman—and was seen in the original by him in 1951—as having a sagittal crest but of which the occiput is missing. In actual fact the greater part of the occiput is present but is a bit distorted and displaced. Fortunately a part of the critical region is preserved and this shows that no nuchal crest was present in the midline. To the right of the midline the superior nuchal line is thickened more than is the case in the Makapan occiput but not so much as in Rhodesian man. On the left of the midline the bone is damaged. Here again there is no evidence of a powerfully developed, shelf-like nuchal crest. A third specimen, *SK* 49 from Swartkrans, also has the anterior part of the sagittal crest preserved as well as a good deal of the occiput, and in this also there is no shelf-like nuchal crest, nor does the sagittal crest reach back to the occiput.

The observed facts show clearly that the conditions necessary for the formation of a powerful nuchal crest were not present in the australopithecine skull, while those necessary for the formation of a partial sagittal crest sometimes did occur. A relatively small amount of expansion of the anterior part of the neurocranium would have resulted in the removal of the conditions giving rise to the latter also. Zuckerman's conclusion that the nature of the australopithecine occipital region does not support the contention that they were bipedal is therefore not consistent with the facts.

A recently prepared specimen, which has not yet been described, is of very great importance with regard to the posture of the australopithecines. A detailed description of this specimen will be published elsewhere; but because it has so direct a bearing on the matter here discussed, a few salient features will be mentioned. The specimen, from Sterkfontein, consists of nine thoracic vertebræ with a number of ribs, all the lumbar vertebræ, the greater part of the sacrum, the right innominate (previously known), and most of the left innominate, as well as a considerable portion of a femur. The spinal column was articulated but the innominates and sacrum were displaced. The sacrum is simply a small edition of the euhominid bone and has a well-developed promontory—which is, however, not so well developed as in modern man. The pelvis, when assembled, is very similar in the general proportions and orientation of the bones to that of man and differs very sharply from the pongid homologue. This is especially apparent in the orientation of the iliac blades and the shape and orientation of the pelvic canal. Lack of space prohibits full discussion of these and other features here; but detailed study of this remarkable specimen shows clearly that it belonged to a bipedal creature. This is fully consistent with the cranial features such as lack of nuchal crest, orientation of the occiput and position of the foramen magnum—the last especially in the Swartkrans prehominid.

Dart, R. A., *Amer. J. Phys. Anthrop.*, n.s., 6, 259 (1948).

[3] Robinson, J. T., *Amer. J. Phys. Anthrop.* (In the press).

THE essay[1] to which Dr. J. T. Robinson refers is mainly an account of the development of the sagittal and nuchal crests; of the balance of the skull; of the anatomy of the temporo-mandibular joint; and of the way teeth become worn. This study showed that in apes and monkeys a sagittal crest is almost invariably associated with a nuchal crest and with a simian planum nuchale. It also showed that if one of the two crests is missing, it is almost invariably the sagittal crest that is lacking. For this reason I suggested that unless *Paranthropus crassidens*, the australopithecine from Swartkrans, is a single exception to a morphogenetical process common to all known Anthropoidea, it followed that its possession of a high sagittal crest implied that it had possessed a powerful nuchal crest or occipital torus.

Dr. Robinson now states that there is "direct evidence" to show that the general proposition "sagittal crest implies the presence of nuchal crest" did not apply to the Australopithecinae. Anything is, of course, possible, and the idea that the australopithecine apes do, in fact, constitute an exception to what seems to be an otherwise general morphogenetic rule is consonant with other claims that have been made for these fossils. But what is possible is not necessarily probable, and certainly does not follow from the so-called direct evidence which Dr. Robinson now cites.

This evidence consists of, first, the occipital fragment of a calvarium from Makapan which was originally described by Dart in 1948[2]. In this specimen, as Dr. Robinson points out, the temporal lines are separated posteriorly, but converge as they pass forward, although they remain separated in the specimen "by an interval of not more than 5 mm."[4]. Dr. Robinson suggests that the point where the specimen is broken is well behind the vertex, and he argues that the lines "*must* have fused farther forward [italics mine]—hence there must have been a sagittal crest". *Ergo*, a sagittal crest is not necessarily associated with a shelf-like nuchal crest.

Quite apart from the novelty of this logic, the "must" is completely unjustified. In female chimpanzees and gorillas, particularly in those which are 'adult' but not fully mature, the temporal lines usually diverge posteriorly, and approach most closely or even meet in the midline behind the bregma, without forming any sagittal crest. This point was recognized by Dart in his detailed description of the Makapan specimen. The fact that the sagittal and lambdoidal sutures of the calvarium had not completely fused suggests that the animal to which it belonged was not fully mature. The lambda area is abnormal, due to the presence of "a sutura transversa occipitalis . . . with subsidiary sulci", but there is nothing remarkable in the disposition of the temporal lines in the specimen as compared with modern apes. Had the animal lived longer than it did, it is possible that the sagittal lines would have met, and it is even conceivable that a sagittal crest may in due course have been formed. Had this, however, been the case, one would have expected the superior nuchal lines to have formed a much more marked crest than they do, especially laterally.

The second specimen which, according to Dr. Robinson, presents features that controvert the proposition sagittal crest presupposes nuchal crest, is Swartkrans *SK* 48. The 'official' description, with photographs (Plate 3) of this specimen, appears in Broom and Robinson's monograph[3]. Here, the occipital region is described as being "very considerably crushed upwards and forwards". Dr. Robinson now says that the greater part of the occiput is present in the specimen, "but is a bit distorted and displaced". The excellent cast that is available in the British Museum conforms to the original description. Regardless of this unexplained discrepancy, Dr. Robinson's point that the nuchal crest was deficient in the midline, though present to the side, is also misleading, if he is intending to imply that this is something different from what occurs in adult apes. Again, the fact is that in chimpanzees and gorillas (especially the female), the least prominent part of the nuchal crest is not infrequently in the midline. One reason for this is that the first part of the occipital torus to form in monkeys and apes is the lateral end, where the temporal lines begin to fuse with the occipital crests. This, as I suggested in the essay to which Dr. Robinson refers, implies that the posterior horizontal and oblique fibres of the temporal muscles grow more rapidly than its anterio and vertical fibres. The description I gave was in no sense complete, and my observations about the further development of the temporal lines applied mainly to those animals (for example, male gorilla and male baboon) in which a sagittal crest is bes developed. In these, the primary meeting point o the two temporal lines is usually towards the posterio part of the sagittal suture, a fact which again can only reflect the relative rate of growth of the posterior horizontal and oblique fibres of the temporal muscles in these creatures. But in the orang outang the temporal lines meet more anteriorly sometimes just behind the bregma, and usually about midway between the bregma and the inion This is what also occurs in the female chimpanzee in which a sagittal crest does not develop, and in the male chimpanzee, in which a crest occurs only occasionally. In those unusual cases where a sagitta crest develops in the gibbon, the temporal lines having fused postero-laterally with the occipital crests usually meet each other just behind the bregma. In many monkeys, again, the upper borders of the sagittal lines do not meet, but remain parallel to each other, in spite of the presence of a strong occipital crest. What is said here applies only to the monkeys and apes. In the loris, a primate belonging to the suborder Prosimii as opposed to Anthropoidea, a sagittal crest may develop over the vertex of the skull, even though the nuchal crests are present only postero-laterally.

The third specimen, which, according to Dr Robinson, presents features that controvert the proposition "sagittal crest presupposes nuchal crest", is *SK* 49. This skull has apparently not been described before, and the amount of information provided now makes it impossible to comment on Dr. Robinson's observations. It would be interesting to know if the posterior part of the sagittal crest (or suture) and the occipital region are better preserved than they are in *SK* 48, or in the second apparently female skull described in Broom and Robinson's original monograph.

The fourth piece of 'direct evidence' to which Dr. Robinson refers relates to a series of post-cranial bones. Whatever these may reveal, they have no direct bearing on the general proposition "presence of sagittal crest presupposes existence of nuchal crest", which to the best of my knowledge is based upon the generality of known facts about the morphogenesis of the primate skull. In any event, now that part of a manifestly human mandible has been found in the same deposits as have yielded the australopithecine apes[4,5], it will be necessary to decide what post-cranial bones relate to what cranial fragments before drawing conclusions about the correlation or lack of correlation of cranial and post-cranial features in the whole group of these fossils.

Measurements on the Neutron Multiplication in a System of Uranium Rods and Ordinary Water

In order to determine the multiplication constant of a system of uranium rods and ordinary water we have made two different experiments with a radium–beryllium source.

A total of 129 uranium rods, 30 mm. in diameter and about 2 m. long, were suspended in a hexagonal lattice in a tank with distilled water. The lattice constant was varied from 40 mm. to 65 mm. in steps of 5 mm. The uranium rods were encased in aluminium tubes, 0·3 mm. thick. The tank had a diameter of 1·2 m. and a height of 2 m. Since the diameter of the uranium core was always less than 0·8 m., the water reflector could in all cases be considered infinitely thick. As detectors, we used boron trifluoride chambers.

(1) Some ordinary exponential experiments[1] were carried out. From these measurements we can calculate the material buckling or 'Laplacian', B_m^2, and obtain the infinite multiplication constant, k, from the formula

$$B_m^2 = (k - 1)/M^2, \qquad (1)$$

where M^2 is the migration area for fission neutrons.

Due to the presence of the water reflector, the radial part α^2 of the buckling cannot be calculated from the extrapolated radius. We have instead calculated it from measurements near the centre of the core, where the influence of the reflector is small. If, in this region, the neutron density can be expanded in a power series,

$$n(r) = A - B r^2 + C r^4 - \ldots, \qquad (2)$$

it is easy to show that the radial part of the buckling at the centre is

$$\alpha^2 = 4 B/A. \qquad (3)$$

For the tightest lattices, irregular fluctuations in the measured distribution prevented the determination of the radial buckling.

Far away from the source the neutron density decays exponentially in the axial direction, and a relaxation-length $1/\gamma$ is measured. For intensity reasons the higher harmonics were not negligible, where the radial distribution was measured, and therefore corrections have to be applied to the axial buckling, $-\gamma^2$, valid for exponential distribution.

For M^2 we have used the value 45 cm.^{2}, which is probably accurate to 10 per cent.

(2) We have also used an integrating method due to Heisenberg and Wirtz[2]. In this case the source was placed in the middle of the core, and the total number of neutrons in the core (N_c) and in the reflector (N_r) were determined by integration. The strength of the source was calibrated by measuring the total number of neutrons (N_s) with uranium rods removed. From these data the multiplication constant can be calculated by means of the formula:

$$k - 1 = \frac{\Sigma_s(N_r - N_s)}{\Sigma_c N_c}, \qquad (4)$$

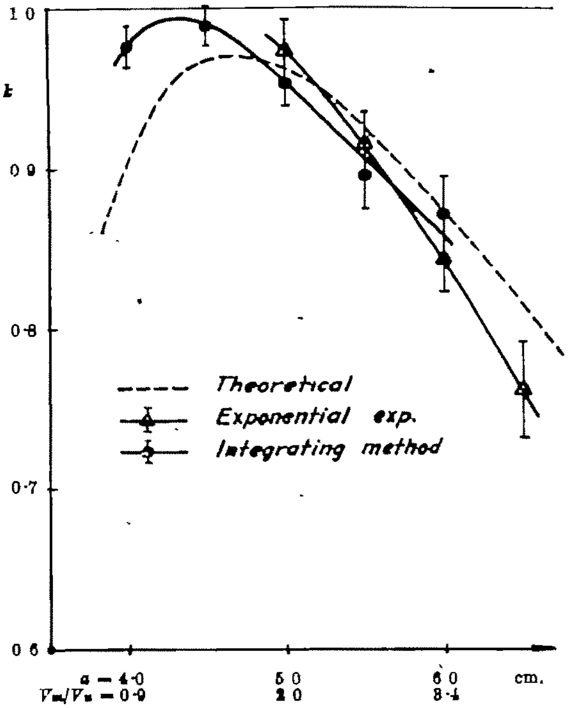

Fig. 1

where Σ_0 and Σ_c are the macroscopic absorption cross-sections of the water and the core respectively. We have, however, to apply some corrections to this formula. On account of the fast fission effect in uranium-238, the number of source neutrons will increase before they reach thermal equilibrium. Therefore, the quantity N_0 must be multiplied by a factor larger than unity. Further, N_c must be divided by the resonance escape probability.

The two experimental curves of the multiplication constant as a function of lattice spacing are compared in Fig. 1 and are seen to be in good agreement with each other. Also shown in this diagram is a theoretical curve[1]. In calculating this curve account has been taken of fissions produced by fast neutrons from one rod in the adjoining rods as well.

Further information about this experiment will be published elsewhere.

Spontaneous Fission Properties of Elements 97, 98, 99 and 100

Isotopes of several heavy elements ($Z = 94$–100) have recently been produced in the Materials Testing Reactor (MTR) in Arco, Idaho. It has thus been possible to extend the data on partial spontaneous fission half-lives to isotopes of berkelium, californium, element 99 and element 100 [1–3]. Table 1

Table 1. NUCLEAR PROPERTIES OF SOME ISOTOPES OF ELEMENTS 97, 98, 99 AND 100

Isotope	Ref.	Radiation	Half-life	Alpha energy (MeV.)	Spontaneous fission half-life	Predicted spontaneous fission half-life from Z^2/A
$^{249}_{97}$Bk	3, 4	β^-	~ 1 yr.	—	> 10^{7} yr.	—
$^{246}_{98}$Cf	6	α, spontaneous fission	35·7 hr.	6·75	2·1 ± 0·3 × 10^{3} yr	1·2 × 10^{3} yr
$^{248}_{98}$Cf	6	α, spontaneous fission	205 ± 40 days	6·26 ± 0·03	~ 7 × 10^{3} yr.	10^{4} yr.
$^{249}_{98}$Cf	3, 4	α	400 ± 100 yr.	5·81 ± 0·03	> 10^{6} yr.	—
$^{250}_{98}$Cf	3, 4	α, spontaneous fission	9·4 ± 2·3 yr.	6·03 ± 0·01	1·4 ± 0·5 × 10^{4} yr.	2·8 × 10^{5} yr.
$^{251}_{98}$Cf	3, 4	(α)	—	—	—	—
$^{252}_{98}$Cf	3, 4	α, spontaneous fission	2·1 ± 0·4 yr	6·12 ± 0·01	60 ± 12 yr.	8 × 10^{6} yr.
$^{253}_{98}$Cf	3, 4	β^-	18 ± 3 days	—	—	—
^{253}99	1, 2	α	19·3 ± 0·3 days	6·61 ± 0·01	> 10^{5} yr.	—
^{254}99	2	β^-	37 ± 1 hr.	—	> 10 yr.	—
^{254}100	1, 2	α, spontaneous fission	3·3 ± 0·2 hr.	7·17 ± 0·01	220 ± 40 days	70 yr.

gives a summary of the nuclear properties of several isotopes of these elements.

The measured partial spontaneous fission half-lives of californium-246 and -248[6] agree reasonably well with the values predicted for even-Z even-A nuclides from the graphs of Seaborg[7] and Whitehouse and Galbraith[8], who plotted the logarithms of the spontaneous fission half-lives of several nuclides as a function of their Z^2/A values. The measured spontaneous fission half-lives of the heavier even-A californium isotopes, however, deviate seriously from the Z^2/A relationship. The spontaneous fission half-lives of the californium isotopes, given in Table 1 and plotted in Fig. 1, support the idea that the even-A isotopes of each even-Z element go through a maximum stability for spontaneous fission as A increases[9].

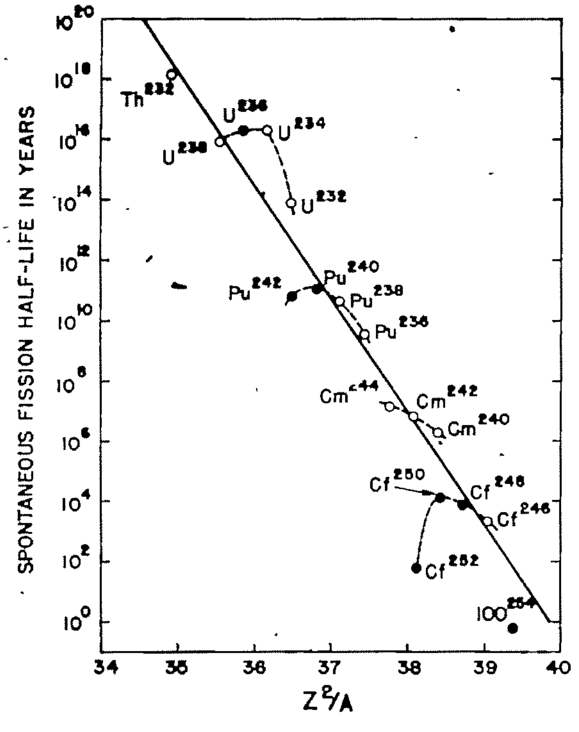

Fig. 1. Spontaneous fission half-lives as a function of Z^2/A. Open circles represent the early spontaneous fission data through which the straight line was drawn (ref. 7). Solid circles are recent spontaneous fission half-lives. The broken lines illustrate the maximum stability toward spontaneous fission (ref. 9) for each element

As a consequence of this spontaneous fission half-life relationship, one has to revise previous ideas of nuclear stability. For a given even value of Z, spontaneous fission decay competes more favourably with alpha-decay as the even-A masses are increased; and as a result, spontaneous fission becomes a competing mode of decay at lower values of Z than previously expected. In fact, the heavier even-A beta-stable isotopes of even-Z elements (Z = 98, 100, etc.) may decay principally by spontaneous fission.

The spontaneous fission decay-rates of the heavy odd-nucleon isotopes given in Table 1 are several factors of ten slower than corresponding even–even nuclides, in agreement with the spontaneous fission half-lives[7] of other odd-nucleon isotopes.

The observed yields of californium-252 in neutron bombardments of plutonium in the Materials Testing Reactor (MTR) in association with the high specific spontaneous fission activity of this isotope makes it attractive as an experimental neutron source.

Inelastic Scattering of 14-MeV. Neutrons by Lithium-7

THE nuclear-level scheme for lithium-7 given in he review article on light nuclei by Ajzenberg and Lauritsen[1] indicates levels at 0·478, 4·61, 6·56 and 7·46 MeV. excitation. The level at 7·46 MeV. corresponds to a resonance in the ^{6}Li(n,^{3}H$_1$)^{4}He reaction at a neutron energy[2] of 0·25 MeV., but neither (p,p'), nor (d,d'), nor (α,α') scattering experiments have revealed inelastically scattered particle groups corresponding to this level[3].

We have studied the inelastic scattering of fast neutrons by lithium-7, using a photographic plate loaded with natural lithium. In this work advantage was taken of the fact that the levels of interest are unstable with respect to alpha-particle and triton emission. The loaded plates (Ilford 200 μ E_1 with 52 mgm. per c.c. loading) were exposed to 14·1-MeV. neutrons produced by the ^{3}H$_1$(d,n)^{4}He reaction, and the plates were searched for the occurrence of alpha-particle and triton pairs of tracks produced by the reaction :

$$^7\text{Li}(n,n')^{7*}\text{Li}(t)^4\text{He}\,; \quad Q = -2{\cdot}465 \text{ MeV.} \qquad \text{(i)}$$

The scattered neutron was not detected in this experiment. The only measurements made were of he energy released to the alpha-particle and triton when the recoiling and excited lithium-7 nucleus decayed within the emulsion. By suitable processing of the plates, good discrimination was obtained between the alpha-particle and triton tracks. The events appeared as a thick and a thin pair of tracks having a common point of origin, and were easily ecognized against a background of recoil protons and single alpha-particles arising from other emulsion constituents. Measurements were made on the ranges and angles of emission of the alpha-particle and triton tracks with respect to the incoming neutron direction.

Provided that the interpretation of the event is correct, these data are sufficient for the calculation of the excitation energy $\epsilon(^7\text{Li})$ of the states of ithium-7 involved in the reaction and, in addition, he energy E_N of the incoming neutron. The expressions obtained for both these quantities involve the same factors, and the value of E_N deduced provided a sensitive test of the accuracy of the individual measurements and of the correctness of the identification of each event. Only those events which inferred an incoming neutron energy within prescribed limits on either side of 14·1 MeV. were accepted.

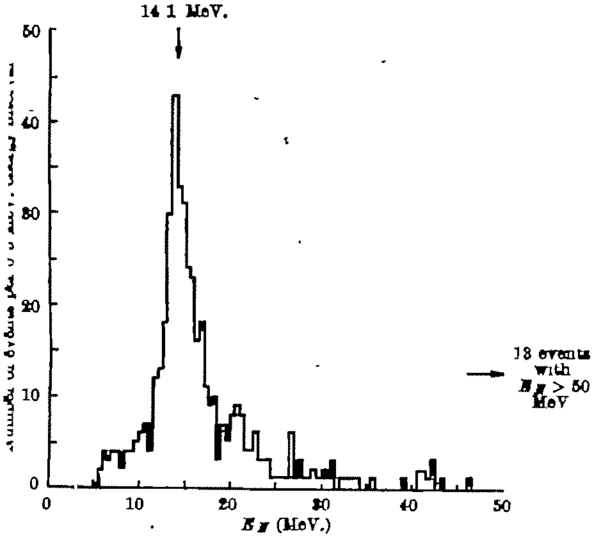

Fig. 1

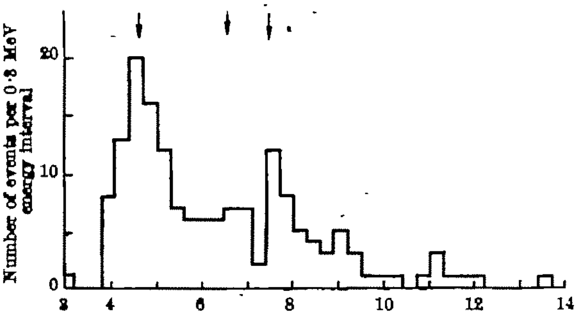

Fig. 2

The frequency distribution of E_N values calculated from the data obtained from measurements on 427 events is given in Fig. 1. The peak occurs at an energy of 14·0 ± 0·25 MeV. and has a half-width at half-height of 1·5 MeV.

Fig. 2 gives the distribution obtained for $\epsilon(^7\text{Li})$ measured in MeV. above the ground-state, assuming the Q value given for reaction (i). Only events satisfying the acceptance limits for E_N (11–18 MeV.) have been included, and this has eliminated many events due to reactions other than (i) which produce heavily ionizing and lightly ionizing particle-pairs of the type measured. Suitable corrections have been applied to remove the background of such events which could have produced E_N values within these limits. In particular, Fig. 2 has been corrected for a considerable background of events due to the reaction :

$$^7\text{Li}(n,t)^5\text{He}(n)^4\text{He}\,; \quad Q = -2{\cdot}465 \text{ MeV.} \qquad \text{(ii)}$$

The background corrections applied made little difference to the shape and position of the groups in the $\epsilon(^7\text{Li})$ distribution in the range 0–9 MeV., although the fully corrected distribution given has been reduced to a total of only 167 events. Most of the events removed appeared in the uncorrected $\epsilon(^7\text{Li})$ distribution in the range 9·2–13·5 MeV., and these events, when recalculated according to reaction (ii), fell into two groups representing helium-5 excitation energies of 0 ± 0·3 MeV. and 2·4 ± 0·6 MeV. A distribution of $\epsilon(^7\text{Li})$ values corrected on the assumption that only the ground-state of helium-5 is involved in reaction (ii) shows a prominent peak at 9·25 ± 0·25 MeV. which may represent a new level in lithium-7.

In Fig. 2 the prominent group at 4·6 ± 0·25 MeV. is identified with the level in lithium-7 at 4·61 MeV. (see ref. 1). The smaller group at 7·5 ± 0·25 MeV. is identified with the expected level at 7·46 MeV., and the group of events between 6 and 7 MeV. is presumably due to the broad level reported[3,4] at 6·56 MeV.

Dielectric Properties of Tellurite Glasses

In a previous communication, Stanworth has described the properties of glasses containing a high percentage of tellurium dioxide[1]. Some data were presented on the optical and dielectric properties of several of such glasses. The purpose of this communication is to record the results of further dielectric measurements on tellurite glasses, carried out at the Physical Laboratory of the National Defence Research Council of the Netherlands (The Hague), in close co-operation with Mr. Stanworth of the British Thomson-Houston Co., Ltd., Rugby, where the samples for this investigation were prepared.

Table 1

	Resonance measurement								Coaxial line	Rectangular wave-guide
Frequency (Mc./s.)	0·07	0·2	0·7	1·5	4	9	20	68·5	1,000 2,000 1,200 3,000 4,590 1,500 4,000 5,190	7,520 9,375 24,000
ε′	26·0	25·9	25·9	26·0	26·0	25·9	26·2	26·2	25·5	25·5
ε″	0·06	0·06	0·06	0·05	0·06	0·05	0·06	0·05		
tan δ	0·002	0·002	0·002	0·002	0·002	0·002	0·002	0·002	<0·01	<0·01

Precision measurements of the dielectric constant and loss angle were made on a glass of molecular composition $BaO.5TeO_2$. The measurements between 0·07 and 68·5 Mc./s. were made with an accuracy of 1 per cent, using the resonance method of Hartshorn and Ward; the measurements between 1,000 Mc./s. and 5,190 Mc./s. were made to an accuracy of about 1½ per cent by impedance measurements on coaxial line equipment, and those between 7,520 and 24,000 Mc./s. to an accuracy of about 1½ per cent using impedance measurement in rectangular wave-guides. The results are shown in Table 1.

The results are similar to those reported for tellurite glass of somewhat different composition in Mr. Stanworth's communication. It appears that the tellurite glasses can have high dielectric constant and low loss-angle up to very high frequencies, showing no frequency dependence, indicating the absence of relaxation up to 24,000 Mc./s. Thus tellurite glass constitutes material of high dielectric constant with very good microwave properties.

Cataphoresis of Crystal Nuclei

From his investigation of crystal formation in supersaturated electrolytic solution and the analysis of the electric behaviour of the crystal solution interface, Ubbelohde[1] has suggested that charged microcrystals which act as crystallization nuclei might exist in the solution. In the course of work on the mechanism of crystal formation, I have observed some phenomena which seem to support Ubbelohde's views.

(1) *Electrolytic crystal formation.* A saturated solution (at 25° C.) of sodium nitrate was electrolysed between two platinum electrodes for 10 hr., at a constant temperature of 15° C., 0·4–0·5 V./cm., current density 2–5 × 10^{-4} amp./cm.[2]. Solute crystals appear first only on the cathode and in its neighbourhood; the initial crystallization is never found in the anodal region (Fig. 1*a*). Fig. 1*b* shows the sam phenomenon on a small scale under the microscope In both cases, crystal formation occurs selectivel only on the cathode side. Considering that th mobility of the sodium ion is greater than that o the nitrate ion in this case, and that the concentratio polarization owing to transport phenomena may b assumed to be negligibly small[3], it is plausible t assume that the phenomenon is due to cataphoresi of the charged crystal nuclei toward the cathode.

(2) *The creeping of salt solution and the interfacia potential.* If it is really the case that the crysta nuclei move electro-cataphoretically toward th cathode, a glass surface[3], being negatively charge with respect to the electrolytic solution, shoul behave like a cathode and cause the occurrence o cataphoresis and crystal formation. This is the well known creeping phenomenon[4]. I find that the creep ing never occurs when the glass container has bee previously treated with (1) silver nitrate solution[5] o (2) aluminium ion[6], both of which cause reversal of the potential at the glass-solution interface. Silica glass, which has no ionic structure, has also failed to show the creeping. These observations are indirect evidence of the electro-cataphoretic nature of crysta nuclei.

(3) *Accelerating effects of the very high-frequenc field on the crystallization process.* It has bee observed that very high frequency (λ = 30–40 cm. accelerates the deposition of crystals in super saturated electrolytic solution[6] (for example, pot assium chloride, potassium nitrate and lead nitrate) but it shows no effect on a non-electrolytic solution (for example, urea). This supports the idea of th existence of charged nuclei in the solution, becaus the chance of collision between the nuclei or betwee a nucleus and an ion should be increased by th effect of the alternating field, resulting in the accelera tion of crystal formation.

(4) *Deviation of sedimentation path of crystallit by the electric field.* Each of the observations men tioned above suggests that there exist charged crysta

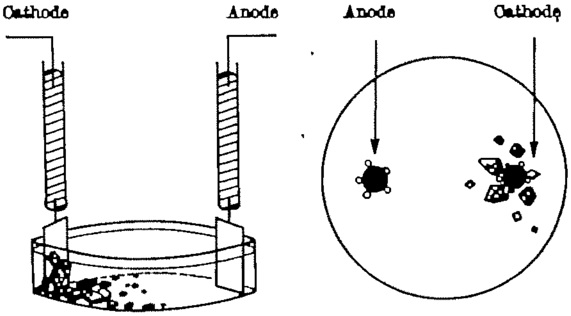

Fig. 1. Electrolytic crystal formation of sodium nitrate; (*a*) large scale; (*b*) on a microscope stage (×16)

uclei and that they move electro-cataphoretically, he size of a nucleus[9] being less than 10^{-6} cm., the atio charge to mass being sufficiently large. Even f the particle size were larger than in the above ase, it may still be expected that cataphoresis will ccur if their surfaces are fresh and the electric field s strong enough. In order to test this expectation, reshly deposited potassium chloride crystallites were llowed to sediment in the supersaturated solution. An external electric field was applied momentarily o the solution (between two carbon rods in the ontainer, 150 V./cm.) immediately after the appearance of the crystallites. The sedimentation paths were deflected a little to the cathode, though the ituation was somewhat blurred, probably by the heterogeneity in the dimensions and forms of rystallites and also by the thermal convection ccompanying the change of phase.

In short, all these observations support the view put forward by Ubbelohde.

RECENT observations on the crystallization of lithium sulphate by Helen Rae and A. E. Robinson may possibly provide a further example of the formation of crystallization nuclei bearing a net charge with regard to the solution[1]. Attention may be directed to the interest of this mechanism of migration of nuclei of ionic crystals. With reference to the deposition of crystalline masses at controlled places in animal systems, it is conceivable that the formation of bones and teeth, for example, are controlled by the direction of nuclei from supersaturated solutions through the intervention of the appropriate electric fields in the surrounding system. The deposition of crystals associated with certain diseases may also be related with the phenomenon under discussion.

A Modified Differential Refractometer

THE light-scattering method of molecular weight determination involves the measurement of the difference in refractive indices of a solution and its solvent. To this end special differential refractometers of high precision have been constructed with[1] or without autocollimation[2,3]. A hollow glass prism is placed within a rectangular glass cell filled with the solvent, and the inner prismatic cell is filled with solution. A beam of parallel light traversing this double cell is deflected by an angle proportional to the difference of refractive indices of the two fluids.

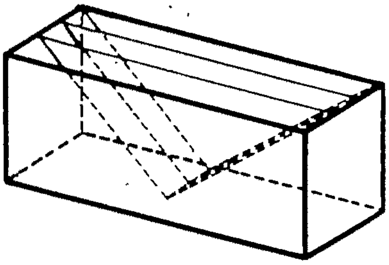

Fig. 1

I have modified this double cell in such a way that part of the parallel beam traverses only the outer cell, passing beside or under the hollow prism. I have thus obtained simultaneously the undeflected and the deflected image of the slit in the measuring microscope; the difference may be read directly in a single measurement without having to change the contents of the hollow glass prism. Errors caused by mechanical derangement or variation of temperature during the change are thus avoided.

A further modification operates with a horizontal slit instead of the usual vertical one, and the rectangular cell contains two hollow prisms instead of one, resting with their apex edge on the bottom of the cell (Fig. 1). Each prism occupies a third of the vertical transverse section of the rectangular cells, leaving a third free for the light beam to bypass them. The rectangular cell is filled with solvent, one of the hollow prisms with the solution to be measured and the other one with a solution of known refractive index for calibration. Thus the difference to be measured and the calibration value may be read simultaneously in one measurement. The fact that the hollow prisms stand on their apex edges makes it possible to use them with a small volume of solution, solely at the cost of light intensity owing to the reduced aperture available.

Solutions may be made up in this refractometer to a given value of difference in refractive indices by filling an appropriate solution into the calibration prism and diluting the other one with solvent from, for example, a burette until the lines—now horizontal—coincide in the microscope.

I wish to acknowledge the help of Mr. F. Dullion and Mr. J. Szántó in the construction of the new cell.

Structure of Collagen

A DETAILED X-ray study of collagen fibres obtained from different sources (namely, shark ray, rat tail tendon and kangaroo tail tendon) and a re-examination of the published wide-angle patterns indicate that the unit cell of collagen is hexagonal with $a = 12–16$ A. and $c = 9·5–9$ A., the actual values depending on the moisture content. The essential difference of this indexing from those reported earlier[1-3] is that the 2·86-A. meridional arc is here interpreted not as a true meridional reflexion, but as arising from the superposition of two close non-

Table 1

Indices	Dry $a = 13 \cdot 3$, $c = 9 \cdot 55$ A obs.	calc.	Wet $a = 15 \cdot 0$, $c = 9 \cdot 20$ A. obs.	calc.
100	11·4	11·5	12·9	13·0
200	5·75	5·75	6·5	6·5
210	4·3	4·34	4·8	4·92
101	7·4	7·35	7·6	7·50
201	4·8	4·92	—	4·46
112	3·9	3·87	3·95	3·93
212	3·3	3·22	3·4	3·36
113	2·86	2·87	2·82	2·84
001	—	9·55	9·2	9·20

meridional reflexions. A calculation of the angular spread of the arc, using the tilt of the c-axis deduced from the spread of the equatorial reflexions, confirms this interpretation. Table 1 shows the good agreement between the calculated and observed spacings of an air-dried and a wet specimen from kangaroo tail tendon.

A structure has been obtained (Fig. 1) which fits the above unit cell and which appears to be in good agreement with infra-red, X-ray and chemical data for collagen. It consists of nine amino-acid residues per unit cell, which corresponds to the observed density. These are linked together to form cylindrical rods, which occur in a hexagonal array. All the residues have the *trans* configuration, and the latest values of Corey and Pauling[4] for the dimensions of the amide group were used for the calculations. The residues are arranged in the form of three helical chains, each of pitch 9·5 A. (= c) and containing three residues per turn, with the symmetry 3_1. The three helixes are also arranged with a 3_1 symmetry about the c-axis, and they are held together by means of hydrogen bonds to form the cylindrical rods. Two of the three NH groups in each turn of a chain are linked by hydrogen bonds to an oxygen of each of the other two chains, the NH . . . O distance being 2·80 A. The third NH group points outward from the cylinder, and the nitrogen atom forms part of a proline ring. Of the three α-carbon atoms per turn, a hydrogen attached to one of them (R, Fig. 1) could be replaced by a general R group to form an amino-acid residue such as arginine or lysine another (P) takes part in forming the proline ring while the third (G) is in such a position that there i no space for either of its hydrogens to be replace by any other group, so that it could only form par of a glycine residue. These features of the structur could explain the observed range of amino-acid composition for collagen.

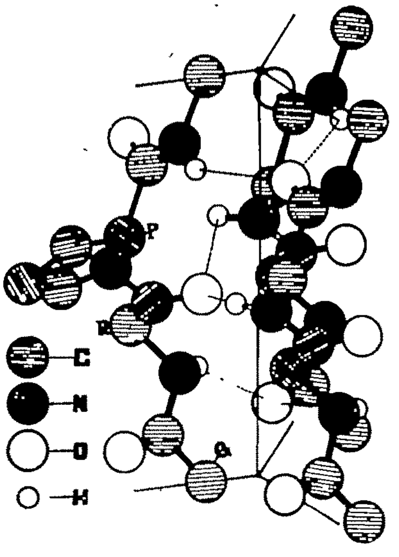

Fig. 1. Diagram showing one of the three-chain cylindrical rods of the structure. The dotted lines indicate the positions of the hydrogen bridges. Only one proline ring is shown, and all hydrogen atoms except those in the NH groups are omitted. The thin lines indicate the directions of the crystal axes

The NH- and CO-bonds are almost exactly perpendicular to the fibre axis, the angle made wit the c-axis being about 85° in both cases. This agree with the observed large infra-red dichroism[5]. Structure-factor calculations show fairly good agreemen with observation. The individual helixes are unstable, and the stability of the cylindrical rods arise from the hydrogen bonds between the helixes. I these are broken, for example, by heating, th structure would crumble down, which would explai the thermal contraction of collagen. The structur could, however, re-form on cooling, as the chain o amino-acid residues in a single helix need not b ruptured in this process.

It may be mentioned that this structure is essentially different from the three-chain structure o Pauling and Corey[2]. The value $c = 9 \cdot 5$ A. is no critical, and a variation of about 15 per cent i permissible without affecting the main features o the structure.

A detailed paper, containing also a discussion o other features of this structure and a critical comparison with previously proposed structures, will be published elsewhere.

Unbiased Ratio Estimators

RATIO estimators are frequently employed in sample surveys when estimating the population mean $\bar{Y}$ of a variate y with the help of the known population mean $\bar{X}$ of a correlated variable x. Confining ourselves to the case of a simple random sample of n pairs y_i, x_i from a population of N pairs, various ratio estimators of $\bar{Y}$ can be formed of which the most important ones are $\hat{y} = \bar{X}\bar{y}/\bar{x}$ and $\tilde{y} = \bar{X}\bar{r}$, where $\bar{y}$, $\bar{x}$ and $\bar{r}$ are the arithmetic means of the sample of y_i, x_i and y_i/x_i, respectively.

One well-known defect of these estimators is the fact that they are usually biased by amounts for which only approximate formulæ are offered in the literature, and, to our knowledge, no general methods are available for the elimination of this bias. It is of some interest, therefore, that quite elementary and exact formulæ for these biases can be obtained which frequently permit the construction of unbiased ratio estimators.

We must confine ourselves here to the simplest cases. It is obvious that

$$E(\tilde{y}) = \bar{Y} - \mathrm{Cov}\left(\frac{y}{x}, x\right) \text{ and } E(\hat{y}) = \bar{Y} - \mathrm{Cov}\left(\frac{\bar{y}}{\bar{x}}, \bar{x}\right)$$

which give the exact formulæ for the bias.

An immediate consequence of these equations are he upper bounds for the biases

$$|\text{Bias in } \hat{y}| \leqslant \sigma_{y/x}\,\sigma_{\bar{x}} \text{ and } |\text{Bias in } \bar{y}| \leqslant \sigma_{\bar{y}/\bar{x}}\,\sigma_{\bar{x}} \qquad (3)$$

which are proved (but only as large-sample approximations) in most text-books. Next, we may try to estimate the exact bias in $\hat{y}$ from the sample. This eads to the unbiased ratio estimate

$$y' = \bar{X}\bar{r} + \frac{n(N-1)}{(n-1)N}\,(\bar{y} - \bar{r}\bar{x}). \qquad (4)$$

If variance formulæ are derived by the customary xpansions in powers of $\Delta y_i = (y_i - \bar{Y})/\bar{Y}$ and $\Delta x_i = (x_i - \bar{X})/\bar{X}$, it can be shown that (for $N \to \infty$) up to and including cubic terms

$$\text{Var } y' = n^{-1}\bar{Y}^2(\sigma_y^2/\bar{Y}^2 + \sigma_x^2/\bar{X}^2 - 2\,\text{Cov}(x,y)/\bar{X}\bar{Y}),$$

which is also the approximate formula for Var $\hat{y}$ and Var $\bar{y}$ if terms up to and including the quadratic are considered. The cubic terms in Var $\hat{y}$ or Var $\bar{y}$ may be positive or negative (depending on certain product moments of the y, x distribution) and are 0 in Var y'. Within the framework of this approximate variance theory, therefore, no large price in variance increment is paid for bias elimination; indeed, for certain populations Var y' is less than Var $\hat{y}$ or Var $\bar{y}$. Similar results are available for bias elimination in $\bar{y}$, and exact variance formulæ have been derived. Since the approximate variance formula depends on the fact that the coefficients of variation of y and x are small, a useful modification consists of the device of splitting the sample of n $y_i x_i$ into (say) K subsamples with means $\bar{y}_j \bar{x}_j$ and computing the unbiased ratio estimate $y' = \bar{r}\bar{X} + \frac{K}{K-1}\,(\bar{y} - \bar{r}\bar{x})$, where $\bar{r} = \frac{1}{K}\Sigma\bar{y}_j/\bar{x}_j$ and N is assumed large.

Adaptations to stratified and multistage sampling have been developed, and it is hoped to publish applications of these estimators shortly.

Solubility of Uroporphyrin I in Ethyl Acetate

ACCORDING to Waldenström, Fink and Hoerburger[1], uroporphyrin I does not pass from aqueous solutions into ethyl acetate at any pH, thus differing from uroporphyrin III, which is readily extracted by ethyl acetate around pH 3·1. This statement has been widely accepted in the literature. We have found, however, that uroporphyrin I in the concentrations studied is readily extracted into ethyl acetate from aqueous solutions at pH 3·0–3·2, and, provided these are strongly buffered, quantitative recoveries can be obtained.

The results of some recovery experiments with uroporphyrin I and 'Waldenström porphyrin' are illustrated in Table 1. The experimental technique was as follows: a solution of the free porphyrin in 0·1 N sodium bicarbonate was added to 50 ml. of 10 per cent (w/v) hydrochloric acid, followed by 150 ml. saturated sodium acetate. The solution was rapidly brought to a pH between 3·0 and 3·2 with concentrated hydrochloric acid and the final volume of solution made up to 250 ml. The order of adding the reagents appeared to affect the recovery materially, and is therefore given in full. The buffered solution was extracted exhaustively with 100-ml. portions of ethyl acetate, readjusting the pH with concentrated hydrochloric acid and saturated sodium acetate between extractions. The last few ethyl acetate extracts are usually non-fluorescent; but extractions were continued until such ethyl acetate layers gave non-fluorescent aqueous layers when shaken with 2 per cent hydrochloric acid. The combined ethyl acetate extracts were then extracted to completion with 2 per cent hydrochloric acid, and this extract determined spectrophotometrically, using the correction factor of Rimington and Sveinsson[2]. It was found that the number of extractions required at each stage was not significantly different for the two isomers; in both cases about 50 per cent of the porphyrin present in the aqueous phase passed into the ethyl acetate during each extraction. The results in Table 1 show clearly that the recovery of uroporphyrin I is not appreciably less than that of 'Waldenström porphyrin'.

Table 1

μgm. Porphyrin added (range)	Percentage recoveries	
	Uroporphyrin I	'Waldenström porphyrin'
46–49	94, 95, 94, 100, 102	99
22–24	99, 99, 102, 99 100	
9–10	100, 89, 94, 95, 97, 97, 101, 99, 101	92, 93
4–5	90, 91, 89, 89 91, 91	95, 86

A suitable method for comparable extraction of both isomers is of value with respect to recent investigations of the porphyrins formed by tissues *in vitro* from precursors such as porphobilinogen and δ-amino-lævulinic acid[3]. A detailed investigation, which we hope to report elsewhere, has led us to conclude that equivalent recovery of each isomer from tissue preparations should also be possible.

The uroporphyrin I used in this investigation was a hydrolysed sample of fraction A(i) shown in Fig. 1 of the paper by Rimington and Miles[4]. 'Waldenström porphyrin' was taken from a bulked sample of Waldenström ester (m.p. 260°, corr.), which, when tested by the paper chromatographic method of Falk and Benson[5], behaved as uroporphyrin III only. Hydrolyses were carried out in 25 per cent hydrochloric acid at room temperature for 36 hr.

We thank Prof. C. Rimington for his support of this work and Miss H. James for technical assistance.

Fractionation of Serum Proteins by Zone Electrophoresis in Glass Powder

In connexion with recent electrophoretic studies of ox serum[1], it became necessary to establish a reliable method for the fractionation of serum proteins which would allow numerous samples to be separated into distinct fractions of sufficient volume and concentration for subsequent physico-chemical and biological characterization. Zone electrophoresis[2] appeared to be the method of choice, and the apparatus here described is a development of that of Svensson and Brattsten[3], whose work should be consulted for the principles involved. The present modifications were introduced to overcome certain difficulties associated with their apparatus, notably the complexity of the feed arrangements and the lack of control of adverse *p*H and electrolytic changes.

The glass-powder bed is supported in a double-walled 'Perspex' trough 27 cm. long, 18 cm. deep and 2 cm. wide. The top of the trough is completely open. 'Perspex' nipples of 1 mm. bore are fitted to the base of the trough at 1 cm. intervals and a strip of closely-woven calico, 27 cm. × 2 cm., is placed inside the trough over the nipple openings to prevent blocking by glass powder. The double walls of the trough form two flat cooling chambers through which is pumped refrigerated water at 2° C. At the ends of the trough are 'Perspex' flanges to which are bolted ion-permeable partitions, electrode chambers and soft-rubber sealing gaskets. The ion-permeable partitions, which have an open area of 16 cm. × 2 cm., constitute the vertical end-walls of the trough and isolate the glass powder bed from the free-flowing buffer solution in the electrode chambers. A typical arrangement consists of a porous ceramic plate at the cathode and a 'Cellophane' membrane at the anode. The electrodes are flat spirals of platinum wire, 1·5 cm. × 15 cm., mounted parallel to and about 1 cm. behind the ion-permeable partitions. Each electrode chamber is sealed, apart from a lower inlet and upper outlet through which buffer solution is pumped continuously at the rate of about 1 litre/min. The return flows of buffer solution from the electrode chambers are mixed in a single 5-litre aspirator bottle prior to recirculation by a centrifugal pump. By this means drifts of *p*H and unstable electrical characteristics arising from accumulations of the products of electrolysis may be completely controlled. This arrangement also overcomes the limitation of current set by the use of reversible electrode systems. The leakage current which by-passes the glass-powder bed is negligible if the rubber connexions of the system are of 1 cm. bore and about 200 cm. long.

The assembly of trough and electrode chambers is fitted to a special rack which may be levelled accurately. This rack also supports a finely adjustable horizontal bar to which are clamped twenty-seven capillary tubes of about 1 mm. bore and 30 cm. length each bent to the form of a J. The longer limbs are connected by fine-bore rubber pressure-tubing to the twenty-seven outlet nipples at the base of the trough. The shorter limbs of the J-capillaries, directed downwards into collecting tubes, terminate at a common level which is about 1–2 cm. below that of the free surface of the buffer solution above the glass-powder bed. The rate of flow of buffer solution through the bed and from the outlet capillaries is determined by the height of the horizontal clamping bar. Regularity of flow from the outlet capillaries is achieved by individual adjustment of the length of each in a preliminary rate-of-flow calibration, and by grinding each tip to an accurate square and smooth finish. The buffer supply to the bed of glass powder is provided by a simple constant-head system. Since the top of the trough is completely open, the multiple syphon system of Svensson and Brattsten[3] is unnecessary.

The protein sample to be fractionated is injected directly into the glass-powder bed at a depth of 3 cm. below its surface. For this purpose a 20–50 ml. glass syringe, provided with a 10 cm. needle bent in the middle at right angles, is mounted horizontally and the plunger advanced by a geared drive from a 1 r.p.m. synchronous motor. A range of protein sample feeds of 0·8–8 ml./hr. may thus be obtained with great regularity.

The completed assembly may be operated in two ways. In the continuous-flow method, following Svensson and Brattsten[3], the buffer solution and protein sample flow continuously while current is passed, and components of distinct mobility follow paths down the glass-powder bed which diverge from the point of injection. This method demands constancy of flow of buffer solution, protein sample and current, but is not seriously influenced by geometrical irregularities of flow density. In the second method, the method of 'no-flow', 5–10 ml. of the protein sample to be fractionated are injected to form a vertical band about 1 cm. wide in the glass-powder bed. The flow of buffer solution and of protein sample are now discontinued and the current switched on. The initial vertical band separates horizontally to form a spectrum of vertical bands spaced across the bed. When the current is switched off, the bands are washed out of the glass-powder bed by a relatively rapid flow of buffer solution equivalent to about 15 ml./hr. at each capillary outlet. Up to twenty-seven fractions each of about 7 ml. are then collected within 30 min. following a separation lasting about 5 hr. This method does not depend upon the constancy of flow of buffer solution or current, but is more sensitive than the first to geometrical irregularities of flow density. The 'no-flow' method is faster than the continuous flow method, since equal resolution may be achieved without lengthy periods at low rates of flow.

With veronal and phosphate buffer systems of *p*H 7·5–9, ionic strength 0·04, and a maximum bed temperature of 30° C., it is possible to maintain a total current of up to 300 m.amp., equivalent to a current density of 10 m.amp./sq. cm., and a voltage between electrode chambers of 300 V., equivalent to a voltage gradient of 10 V./cm. Under these conditions, bovine albumin and γ-globulin separate in the 'no-flow' method at the rate of 3–4 cm./hr. Electrophoretic analyses by the Tiselius method of collected fractions indicate that an almost linear gradient of mobility develops across the glass-powder bed. The mobility-resolution following a separation lasting 5 hr. is about 0·5 $\text{cm.}^2\ \text{V.}^{-1}\ \text{sec.}^{-1} \times 10^{-5}$. The albumin and γ-globulin components of ox serum are separated cleanly. The intermediate α- and β-globulin, however, when collected at the appropriate outlets, may be contaminated with small proportions of the adjacent components. This is probably a consequence of adverse spreading effects and of the poly-dispersity of the protein mixture.

It is hoped to publish shortly further details of suitable ion-permeable partitions and of the separations achieved with ox serum in beds of glass powder and of starch. The significant advantages of the present apparatus in facility of control and in rapidity of separation of components over the entire length of the bed have been demonstrated also in preliminary studies of the fractionation of the sera of cattle infected with the virus of foot-and-mouth disease.

Phosphorus Linkages in α-Casein

RECENTLY, an investigation on the nature of phosphorus bonds in proteins has been initiated in this laboratory. This was stimulated by the observation that a variety of phosphatases will dephosphorylate phosphorus-containing proteins without proteolysis occurring simultaneously. Dephosphorylation, however, takes place only if the phosphate groups are present as monoesters with two ionizable hydroxyls[1,2]. In addition, the occurrence, in phosphoproteins, of linkages such as those of pyrophosphates, —O—P—O—P—O—, phosphodiesters, —O—P—O— or —N—P—O—, and the presence of these bonds in cyclic arrangements, had to be anticipated. Thus, it should be possible to demonstrate such structural units with the aid of specific enzymes which bring about their transformation into monoesters that are then readily hydrolysed by the action of phosphomonoesterases. The work described here was designed to test these assumptions, and supplies the first experimental evidence for the existence of pyrophosphate bonds in a protein. Moreover, it is shown that α-casein, in addition to phosphomonoesters, also contains some of its phosphorus as pyrophosphate and phosphodiesters.

As reported in 1952[3], prostate phosphatase[4], an enzyme specific for the hydrolysis of  $\mathrm{-O-P(=O)(OH)-OH}$, at pH 5·8–6·0 removes 40 per cent of the α-casein phosphorus. If a 1 per cent solution of α-casein in 0·05 N sodium bicarbonate containing 0·01 M magnesium ions is treated at 37° C. with a purified phosphodiesterase from rattle snake venom (*Crotalus adamanteus*)[5], no inorganic phosphorus is liberated. As shown in line 2 of Table 1, the pH of the reaction mixture, however, had shifted from 8·5 to 7·8, indicating the exposure of acidic groups. Subsequent incubation of the protein with prostate phosphatase in cacodylate buffer of pH 6·0 and 0·1 ionic strength results in the appearance of 41·5 per cent of inorganic phosphorus (line 3), an amount corresponding to that liberated by the prostate enzyme from untreated α-casein (line 1). If, however, the α-casein pretreated with diesterase is incubated with both prostate and intestinal phosphatase[6], 78·0 per cent inorganic phosphorus appears (line 4). Since the intestinal enzyme used in this investigation is found to act at pH 6·0 on low molecular-weight substrates of the type  $\mathrm{-N(H)-P(=O)(OH)-OH}$ but not on  $\mathrm{-O-P(=O)(OH)-OH}$[6], and the

Table 1. STEPWISE ENZYMATIC DEPHOSPHORYLATION OF α-CASEIN

Reaction mixture	pH of the reaction mixture	Maximal amount of phosphorus released (per cent of total)	Conclusions	Distribution of phosphorus (per cent of total) as		
				$\mathrm{-O-P(=O)(OH)-OH}$	$\mathrm{-N(H)-P(=O)(OH)-O-}$	$\mathrm{-O-P(=O)(OH)-O-P(=O)(OH)-O-}$
1. α-Casein + prostate phosphatase	6·0	39·6	2/5 of phosphorus present as $\mathrm{-O-P(=O)(OH)-OH}$	40		
2. α-Casein + phosphodiesterase	8·5 → 7·8	0	O—P of diester bond broken			
3. α-Casein (pretreated with diesterase) + prostate phosphatase	6·0	41·5	Same as in line 1	40		
4. α-Casein (pretreated with diesterase) + prostate and intestinal phosphatase	6·0	78·0	2/5 of phosphorus present as $\mathrm{-O-P(=O)(OH)-OH}$ and 2/5 derived from N—P—O	40	40	
5. α-Casein + pyrophosphatase	7·2	0				
6. α-Casein (pretreated with pyrophosphatase) + prostate phosphatase	6·0	59·5	2/5 of phosphorus present as $\mathrm{-O-P(=O)(OH)-OH}$ and 1/5 derived from O—P—O—P—O	40		20
7. α-Casein (diesterase + pyrophosphatase pretreated) + prostate and intestinal phosphatase	6·0	100		40	40	20

snake venom diesterase hydrolyses the —O—P— bond of a diester, it can be inferred that the diester linkage in α-casein is of the —N—P—O— type, in contrast to the —O—P—O— recently found in β-casein[7].

An identification of the remaining phosphorus is then achieved as follows: on incubation of a 1 per cent solution of α-casein in veronal–carbonate buffer of *p*H 7·2[8] containing 0·001 *M* magnesium ions with crystalline yeast pyrophosphatase[9], no inorganic phosphorus is set free (line 5). Subsequent treatment of the protein with the prostate phosphatase at *p*H 6·0 in sodium cacodylate buffer results in the appearance of 59·5 per cent inorganic phosphorus (line 6). Thus the increase of 20 per cent liberated by the prostate enzyme from the α-casein pretreated with pyrophosphatase must originate from monoesters of the type  $-\mathrm{O}-\mathrm{P}(=\mathrm{O})(\mathrm{OH})-\mathrm{OH}$ derived from a pyrophosphate bond, —O—P—O—P—O—. In line 7 of Table 1 the results of an experiment are listed, showing that if α-casein is treated with the phosphodiesterase at *p*H 8·2, followed by incubation with the pyrophosphatase at *p*H 7·2, the intestinal and prostate enzymes at *p*H 6·0 will liberate the entire phosphorus of this protein. These results thus demonstrate that α-casein contains 40 per cent of its phosphorus as monoesters of the type  $-\mathrm{O}-\mathrm{P}(=\mathrm{O})(\mathrm{OH})-\mathrm{OH}$, 20 per cent as pyrophosphates, —O—P—O—P—O—, and 40 per cent as diesters, —N—P—O—.

Complete removal of the phosphorus is accompanied by a disintegration of the protein into smaller units, indicating that the phosphorus links relatively small polypeptides which are soluble in 10 per cent trichloroacetic acid. These fragments can be separated chromatographically by passage through a column of 4 per cent cross-linked 'Dowex 50'.

The presence of the pyrophosphate bond in α-casein, a protein with 0·99 per cent phosphorus[10], can be used for the estimation of the molecular weight. If one-fifth of the phosphorus is present as a pyrophosphate, a linkage involving two atoms of this element, the total number per mole must be ten or a multiple thereof. Since the atomic weight of phosphorus is 31·02, it would give a minimum molecular weight of 31,000, in good agreement with that of 30,000 reported for casein in the literature[11].

I wish to thank Drs. G. Schmidt and M. Kunitz for some of the phosphatase preparations used in this research, and Dr. T. L. McMeekin for supplying the α-casein.

Catalysis of Olefin Autoxidation by Heavy Metal Ions in Non-Polar Media

THE catalysis of autoxidation by heavy metals ha wide ramifications in the fields of biochemistry an chemical industry and is of considerable academ interest. In spite of this, relatively little fundament work has been undertaken except with polar solvents[1].

The special case of the autoxidation of natur and certain synthetic rubbers takes place unde conditions which are essentially non-polar. The marked differences in behaviour might occur a between polar and non-polar media has prompte this investigation. We have studied the autoxidatio of *cyclo*-hexene at 60·0° C. catalysed by the *n*-heptoates of metals in the presence and absence of 10 part by weight of *n*-heptoic acid per 100 parts by weigh of *cyclo*-hexene. An aliphatic carboxylic acid wa chosen as the polar compound in view of the published work using glacial acetic acid[1]. Table 1 show that a very different ranking order for catalyti efficiency is obtained in the presence of *n*-heptoi acid, making it clear that mechanisms deduced fron work in polar media cannot be transferred *a prior* to non-polar media.

Table 1
(Po_2 = 760 mm./mercury)

Metal, initial valency state and concentration	Extent of oxidation after 60 min. reaction (gm. O_2/kgm. *cyclo*-hexene)	
	cyclo-Hexene as medium	*cyclo*-Hexene + heptoic acid as medium
Co^{++} (49·1 p.p.m.)	27	85
Mn^{++} (49·5 p.p.m.)	21*	28
Cu^{++} (50·0 p.p.m.)	13	0·33
Fe^{+++} (500 p.p.m.)	1·3	3·4
Metals absent	0·13	0·34

* The duration of this reaction is taken as 60 min. from the termination of the induction period

The marked difference in behaviour between pola and non-polar media is further emphasized by th kinetic characters of the various systems. Thes differences are shown simply in Table 2.

Table 2

Metal and initial valency state	Variation in rate of oxygen absorption as the total extent of absorption increases	
	cyclo-Hexene as medium	*cyclo*-Hexene + heptoic acid as medium
Co^{++}	rate decreases	rate decreases
Mn^{++}	rate decreases*	rate increases from very low value
Cu^{++}	rate decreases	no catalysis
Fe^{+++}	rate increases from very low value	rate increases from very low value

* With manganese there is a marked induction period followed by the sudden appearance of a well-defined rate.

The induction period for manganese, which is of very variable duration, is eliminated by the addition of a small amount of *tert*-butyl hydroperoxide, indicating that the free radicals required to start reaction chains are derived from the interaction of manganese and hydroperoxide, not by interaction of the manganese and *cyclo*-hexene, and that, therefore, the induction period is determined by the rate at which a threshold value of hydroperoxide concentration is built up independently of the manganese. The same hypothesis may apply to cobalt and copper, although an induction period has not been observed with these metals.

With copper at 50 p.p.m. concentration in the absence of *n*-heptoic acid, the consumption ratio

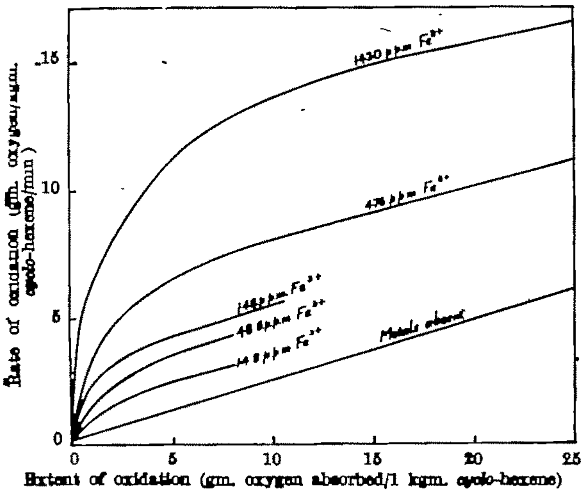

Fig. 1

$d(O_2 \text{ absorbed})/d[ROOH]$ has been accurately determined and found initially equal to unity but increasing somewhat as the reaction proceeds. A similar consumption ratio appears to exist for the reaction catalysed by ferric iron.

We reserve suggestions regarding the mechanism of catalysis in non-polar media except for the ferric iron catalysed autoxidation. The interpretation of this reaction is most readily seen by plotting the rate of oxygen absorption against the amount of oxygen already absorbed, when the graphs shown in Fig. 1 are obtained.

Thus, provided due allowance is made for the simultaneous uncatalysed autoxidation, there is an initially marked dependence of the rate on hydroperoxide concentration, which eventually degenerates into a complete independence as the reaction proceeds.

If we assume a reaction scheme for ferric iron analogous to that postulated for cobalt in glacial acetic acid[1], namely:

$$\begin{array}{llcl}
\text{Initiation} & \left\{\begin{array}{l} ROOH + Fe^{3+} \\ ROOH + Fe^{2+} \end{array}\right. & \begin{array}{c}\rightarrow\\ \rightarrow\end{array} & \begin{array}{l} ROO. + H^{+} + Fe^{2+} \\ RO. + OH^{-} + Fe^{3+} \end{array} \\
\text{Propagation} & \left\{\begin{array}{l} ROO. + RH \\ RO. + RH \\ R. + O_2 \end{array}\right. & \begin{array}{c}\rightarrow\\ \rightarrow\\ \rightarrow\end{array} & \begin{array}{l} ROOH + R. \\ ROH + R. \\ RO_2. \end{array} \\
\text{Main termination} & RO_2. + RO_2. & \rightarrow & \text{Inactive products}
\end{array}$$

then the scheme must be erroneous in at least one respect as it predicts a rate dependent on $[ROOH]$ as well as $[Fe^{3+}]$ until a very advanced stage of oxidation is reached. This discrepancy can be removed by postulating that the rate-determining step in chain initiation is the formation of free radicals by the decomposition of an iron (III) – hydroperoxide complex.

The maximum rate of oxygen absorption is not attained until the molar ratio $[ROOH]/[Fe]$ reaches a high value. Therefore, either there is an equilibrium of the type

$$\text{(Iron (III) – hydroperoxide complex)} \rightleftharpoons \text{iron (III)} + \text{hydroperoxide},$$

or the formation of the complex is a relatively slow process. Experiments are in hand to distinguish between these possibilities.

The apparent differences in kinetic behaviour of the other metals may result partly from the possibilities of the corresponding equilibria being farther to the left and the complexes being formed more rapidly. These factors would result in the maximum rate of oxidation being reached at a very early stage of the reaction, and since these metals are more efficient catalysts than iron, this maximum rate would be developed in such a short time as to escape experimental observation. Work is in hand to study the initial periods of oxidation more accurately. Such measurements may also provide evidence regarding an alternative chain-initiation process, namely, a direct interaction between metal and olefin to give free radicals.

Atoxopyrimidine Action of Vitamins of the B_6 Group

In a previous communication, we recorded that pyridoxamine has a strong atoxopyrimidine action[1]. We now find that, besides pyridoxamine, pyridoxine and pyridoxal also have strong atoxopyrimidine action.

Mice were fed at first for five days on a synthetic diet consisting of purified casein, starch, lard and McCollum salt mixture, supplemented with known B-group vitamins except B_6. Then for five days 0·1 or 2·0 mgm. respectively of pyridoxamine or pyridoxine was given in addition to the above diet, and finally 0·125 mgm. of 2-methyl-6-amino-5-hydroxymethylpyrimidine per gm. body-weight was injected into the test mice. While all the controls to which no additional B_6 was supplied died from severe convulsions, all the test animals were saved from these attacks. (Inhibiting activity, that is, number of survivals/number of test animals multiplied by 100, is 100 per cent.) A daily supplement of 0·05 mgm. of pyridoxine for 5 days gave an inhibiting activity of 75 per cent, and 0·025 mgm. for 5 days gave an inhibition of 50 per cent. With injection of 0·125 mgm. of 2-methyl-6-amino-5-hydroxymethylpyrimidine per gm. body-weight, all mice fed for 7–15 days on the basic diet died, whereas all mice injected with pyridoxamine in amounts of a half to one-fifth of the dose of the simultaneously injected 2-methyl-6-amino-5-hydroxymethylpyrimidine were saved from the attack of convulsions (inhibition, 100 per cent). The simultaneous injection of pyridoxamine in amounts of one-tenth to one-twentieth of the dosage of 2-methyl-6-amino-5-hydroxymethylpyrimidine showed an atoxopyrimidine effect of 50–80 per cent. The simultaneous injection of pyridoxine in dosages of from one-tenth to one-twentieth of the amount of 2-methyl-6-amino-5-hydroxymethylpyrimidine showed an inhibition of

100 per cent. Injection of pyridoxine in a dose of one-fortieth caused an inhibition of 80 per cent.

In the case of feeding with ordinary diet, even the injection of 0·5 mgm. of 2-methyl-6-amino-5-hydroxymethylpyrimidine per gm. of body-weight was not sufficient to bring on convulsions of all test mice. So little as 1·0 mgm. of 2-methyl-6-amino-5-hydroxymethylpyrimidine caused the death of all test animals. In the latter case the simultaneous injection of pyridoxamine in dosages of a half to one-fifth of the amount of 2-methyl-6-amino-5-hydroxymethylpyrimidine saved all the test animals from convulsions and death (100 per cent inhibition). In the case of pyridoxine, injection of a fifth to a tenth of the amount of the pyrimidine compound gave 100 per cent inhibition, and one-twentieth to one-fiftieth gave 80 per cent inhibition. In the case of pyridoxal, a tenth to a two-hundredth of the dosage of 2-methyl-6-amino-5-hydroxymethylpyrimidine gave 100 per cent inhibition, but in dosages of from a four-hundredth to a five-hundredth the effect fell to 50 per cent. The toxicity of pyridoxal itself appeared at more than a fifth of the dose of 2-methyl-6-amino-5-hydroxymethylpyrimidine, and therefore the inhibiting effect upon the convulsions caused by the pyrimidine compound could not be estimated.

We are indebted to Dr. T. Matsukawa for supplying a sample of 2-methyl-6-amino-5-hydroxymethylpyrimidine.

Colchicine-Induced Heteroploidy in Early Mouse Embryos

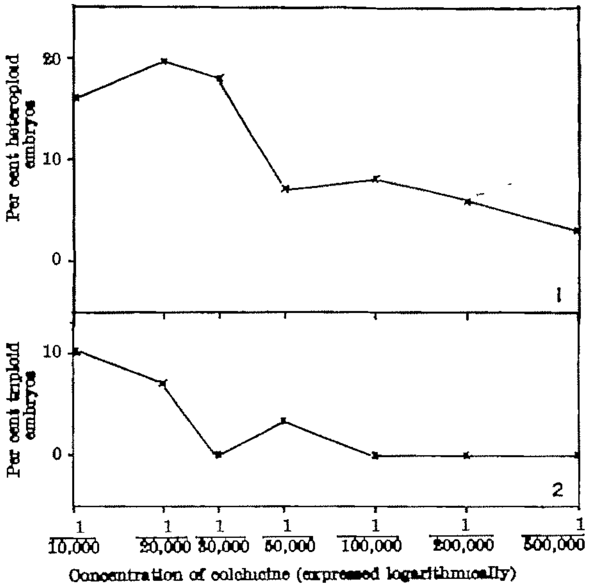
THE induction of heteroploid development in the mouse (*Mus musculus*) has been obtained by the method of temperature treatment of eggs in the Fallopian tube[1,2]. As an alternative method, colchicine, the classical polyploidogenic agent in plants, has been used in mammals other than the mouse. Pincus and Waddington[3] reported a number of one-celled tetraploid rabbit eggs after treatment *in vitro*. Chang[4] and Häggqvist and Bane[5] artificially inseminated rabbits with sperm suspended in a dilute solution of colchicine and observed a proportion of abnormal young at term. In the experiment of Häggqvist and Bane, of those abnormal offspring which came to maturity one was apparently not diploid[6]. Similar experiments with the pig gave one adult boar claimed to be triploid[7]. The heteroploid status of the mature rabbit and boar has, however, been disputed by several workers, for example, Beatty and Fischberg[8].

The following experiment was undertaken to investigate the possibility of obtaining colchicine-induced heteroploidy in the mouse, and if it was obtained, to elucidate the optimal conditions fo treatment. The mice used were of heterogeneou origin. To reduce the level of spontaneous heteroploidy[1,2], mice carrying the silver factor were no used.

By artificial insemination with semen containin colchicine, Chang[4] and Häggqvist and Bane[5] created conditions which probably led to fertilizatio in the presence of the chemical. Colchicine may ente the egg either by general absorption or, more directly by accompanying the fertilizing sperm; and onc in the egg, the colchicine might inhibit the secon meiotic spindle and induce triploidy by retention o the second polar body. But colchicine is also a toxi substance. To reduce toxic effects on the sperm direct treatment of the sperm was abandoned an the following procedure adopted. Œstrous females selected by the vaginal smear technique, were injecte with about 0·1 ml. of colchicine solution through th cervix into each horn of the uterus. They were then paired with males for natural mating. In this way, the sperm was not exposed to colchicine until the mating occurred.

Three and a half days after mating, the females were killed, and the developing embryos washed from the uterus, fixed in aceto-carmine, and made into squash preparations. Chromosome counts were made as accurately as possible (with a maximum error of ±5 per cent of the total chromosome number) on all the clear mitotic figures found, and the embryo was classified on these counts.

By the use of various concentrations of colchicine dissolved in 0·75 per cent sodium chloride, the highest concentration compatible with fertilization and development was found to be 1/9,000 by weight. At higher concentrations no eggs had developed apart from four under-developed embryos taken from two females. At lower concentrations the number of females with developing embryos was always more than 62 per cent and averaged 79 per cent. Examination of the embryos showed that a large number



Relation between colchicine concentration and the percentage of: (1) induced heteroploid embryos (the figures for concentration 1/9,000 have been included in concentration 1/10,000); (2) induced triploid embryos (these figures are also included in 1) were developing as heteroploids, and that these were of various kinds—haploids, hypo-diploids, hyper-iploids, triploids, tetraploids and various mosaics. The heteroploids were produced over a range of oncentrations as shown in Fig. 1. The numbers nvolved in the graph between concentrations 1/9,000 and 1/30,000 are 191 diploid and 44 heteroploid mbryos. Low concentrations of colchicine were used n order to find the lower threshold of activity. Few mbryos were examined at concentrations 1/100,000 nd 1/200,000, the occurrence of heteroploids at these concentrations merely being used as an indication of the continuing action of the chemical. At 1/500,000, however, the effect of the colchicine appeared to be slight, only one embryo being possibly heteroploid out of thirty-one classified. The control figures, obtained by injecting the same quantity of 0·75 per ent sodium chloride solution into the uterus, were 03 diploids and no heteroploids.

The time of mating following injection affected the uccess of the method. If mating was delayed, the percentage of heteroploids resulting was low; if mating was rapid, many heteroploids were found, the difference between the two categories of mating time being statistically significant at the higher con-centrations. The decreased effectiveness of delayed matings is probably due to the absorption of the colchicine by the uterine tissues, or to the inactivation of it by the uterine fluids, or to leakage through the cervix of the injected solution, all of which lead to a ess effective treatment of the egg.

If embryos with mitotic figures of between 55 and 60 chromosomes are classified as triploid (the diploid number of chromosomes in *Mus musculus* being 40), their distribution is given in Fig. 2. The number of triploids is highest at the strongest concentrations and declines to none at 1/30,000 and below, except for a single one found at 1/50,000. A high concentration appears necessary, therefore, to include all the polar body chromosomes within the egg at fertiliz-ation.

Experiments designed to induce tetraploids were made using the same techniques of colchicine injection and embryo recovery. The injections were made about eighteen hours after mating, which is immediately prior to the formation of the first cleavage spindle; and the ntention of the treatment was to suppress the separa-tion of the two diploid chromosome sets on this spindle. Examination of the squashed three and a half day embryos showed that, at concentrations of 1/2,000 to 1/4,000, in addition to many diploids, five tetraploid or diploid-tetraploid mosaics were developing. Presum-ably the tetraploids arose by the action of the colchicine on the first cleavage spindle, and the mosaics by an effect on one of the blastomeres of the two-celled or later stages; in both cases the colchicine having been absorbed on the surface of the embryo.

These results show that colchicine can be used to induce heteroploid development in the mouse, and suggest a wider use for the chemical in the domestic-ated animals[7]. Variation in the time of treatment produces triploids or tetraploids, though various other chromosomal abnormalities are produced. Many of the triploids showed no effect of the chemical cyto-logically, and had cell numbers only slightly less than their diploid sibs. The tetraploids showed some effects of the chemical by the presence of contracted mitoses, and had low cell numbers.

This work has been carried out under the super-vision of Dr. R. A. Beatty. I wish to thank the University of Edinburgh for the receipt of a post-graduate studentship which made the work possible.

Relationship between Maternal Liver Fat and Fœtal Weight in Ovine Pregnancy

It has been shown by Ferguson[1] that there is a considerable rise in total liver fat in healthy sheep at the 135th–140th day of pregnancy, when their food consumption is severely restricted from the 100th day, but that the livers of ewes which are maintained on a high plane of nutrition from the 100th day contain the same small amount of fat towards the end of term as do non-pregnant animals. Dryerre and Robertson[2] did not investigate the effect of plane of nutrition on liver fat during preg-nancy; but in well-nourished ewes they found no difference in liver fat between animals bearing a single and those bearing more than one fœtus, and that there appeared to be no correlation between the lipide content of the liver of the ewe and the growth of the fœtus.

For the first 100 days of pregnancy in the present study, ewes were fed a high-plane diet of swedes, hay and concentrates (crushed oats 30, dried brewers' grains 20, bran 20, linseed cake 10, white fish meal 10, dried molassed sugar beet pulp 8, minerals 2 parts by weight) and showed satisfactory gains in weight. Thereafter a high-plane group of these was maintained on the same diet and continued to increase in weight, while the remainder (low-plane group) received only swedes and oat straw, on which they declined severely in weight.

The weights of the fœtuses and the total liver fat of the ewes which were slaughtered at the end of the pregnancy period are shown in Table 1. Liver fat was estimated gravimetrically as the total ether-soluble fractions. The liver was homogenized with ethanol and then submitted to continuous hot ex-traction for four hours with 97 per cent ethanol. The tissue residues and alcoholic extract were treated to hot continuous extraction with ether for two hours. The ether extract was dried to constant weight.

There is a significant positive correlation ($r = +0{\cdot}99$) at $P = 0{\cdot}05$ between fat in the ewes' liver and the weight of her fœtuses in the case of

Table 1. MEAN VALUES FOR LIVER FAT IN EWES ON HIGH AND LOW DIETARY PLANES, AND WEIGHTS OF THEIR FŒTUSES

Group	No. of ewes	Fœtuses		Total maternal liver fat (gm. per cent fresh liver weight)
		Number	Weight (lb.) per ewe	
High-plane (128th–143rd day of pregnancy)	8	12 (incl. 4 twins)	19·7 ± 1·54	8·87 ± 0·34
Low-plane (135th–140th day of pregnancy)	6	12 (6 twins)	14·4 ± 1·74	26·7 ± 1·90

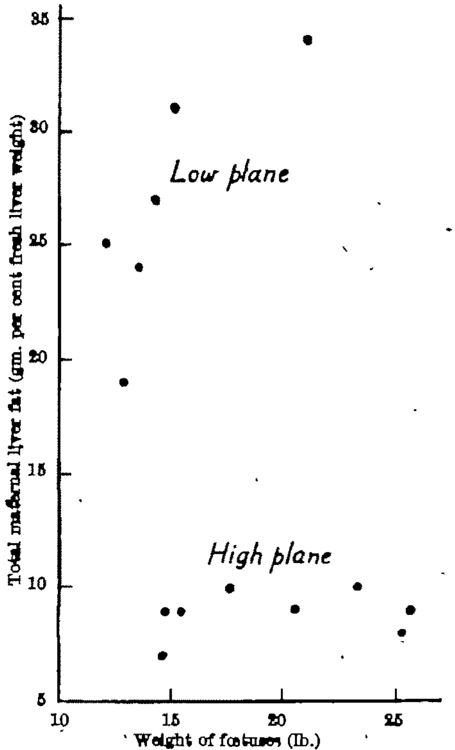

Fig. 1. Relation between total liver fat in ewes on high- and low-dietary planes at the end of pregnancy, and the weight of their foetuses

the low-plane animals, as is suggested by the scatter of points in Fig. 1. The correlation between these two variables in the case of the high-plane ewes ($r = + 0{\cdot}07$) is not significant at $P = 0{\cdot}05$. In the case of these high-plane animals, body reserves never seem to have been drawn on, the carcasses being well furnished with fat. These findings, however, require further investigation with a larger number of animals.

The experiment was made possible by financial assistance from the Agricultural Research Council. Acknowledgment is made of help received from P. S. Pugh, who undertook the analysis for fat.

Wilt of Shisham (*Dalbergia sissoo* Roxb.) due to *Fusarium solani* sensu Snyder and Hansen

Shisham, an important timber species of North India, has been found to suffer from wilt disease in the Dehra Dun and Saharanpur districts in western Uttar Pradesh. The disease occurs both in natural forests and in taungyas which are artificially regenerated with field crops in admixture with other economic species like semul (*Bombax malabaricum*), babul (*Acacia arabica*), khair (*Acacia catechu*), bamboo (*Dendrocalamus strictus*), etc. Only trees of about 15–25 years old suffer from this disease, and wilting has not been observed in the seedling, sapling and pole stages of the plant. The symptoms of wilt in shisham are systemic and are characterized by drooping leaves and branches due to loss of turgor. The leaflets gradually turn yellow, and eventually drop off. The entire tree becomes 'thin' and light coloured, and stands out sharply in contrast to adjoining densely clothed green healthy trees. The nodules and slender branches on roots which characterize healthy shisham are absent on the roots of wilted trees. On splitting the diseased roots, the bark and the outer sapwood exhibit a well-defined pinkish-brown (sorghum brown, army brown, light seal brown, according to Ridgway[1]) stain, and though the stain is restricted in this region, it may rarely penetrate into the inner sapwood. The heartwood is free from the stain. The stain also progresses along the outer sapwood from the roots to the stem and, in the late stage of wilt, it may extend up the stem to about ten feet from the ground.

The wilt disease of shisham was reported by Bagchee[2] to be due to ***Fusarium*** sp. The organism, which is identified as ***Fusarium solani***, has been proved to be soil-borne. The fungus invades the tree through the roots, usually the laterals, whence it travels into the tap root and then proceeds along the stem. Within the wood, the hyphæ of ***F. solani*** are abundant in all the tissues, particularly the vessels. Due to clogging of vessels and adjoining tissues in the sapwood, especially in its outer region through which the sap mainly flows, the water supply to the crown is stopped, or at any rate considerably reduced, as a result of which the crown wilts. Wilting of the crown in shisham starts only when a certain proportion of the roots of a tree is invaded by the fungus. Wilt of leaves and branches thus indicates a late stage in the development of the disease. Death of affected trees is rapid and may occur within a few months after the symptoms in the crown become evident. ***Fusarium solani*** is constantly associated with wilted shisham, from the infected roots and stems of which the organism is consistently isolated in culture. Healthy but dead roots of shisham are quickly infected by ***F. solani*** when such roots are buried in a soil naturally infected by the fungus. These artificially infected pieces of root develop a pink stain in the wood from which ***F. solani*** can be re-isolated, proving that the fungus is responsible for the pinkish-brown stain present in the wood of wilted trees. Thus it is concluded that wilt and sudden death of shisham is due to attack by ***F. solani***.

The behaviour of ***F. solani*** in the soil has been studied in detail. Colonies of the fungus appear frequently in isolations made from the soil by the 'dilution plate' method described by Waksman[3]. 1 gm. of soil is found to contain about 10,000 colonies of ***F. solani***, based on an average of thirty soil samples, and the maximum number of colonies in one sample has been recorded as 40,000 per gm. of soil. The fungus occurs in soils bearing both healthy and wilted shisham and also in soils which support vegetation other than shisham, so that the occurrence of the fungus is independent of the presence or absence of the host species. In the soil, ***F. solani*** is usually present in the form of mycelium, though the possibility of its occurrence in the form of conidia and chlamydospores also exists. The fungus has been proved to possess quick and wide powers of saprophytic colonization by its ability to colonize healthy but dead shisham roots buried in wilt-infected soil. From these observations, it is concluded that ***F. solani*** belongs to the 'soil-inhabitant' group as assified by Garrett[4]. Detailed results will be pub- hed elsewhere. Studies are in progress regarding e relationship between the host plant, the parasite d the general soil microflora under varying con- tions of soil texture, soil moisture, soil reaction, vailable soil nutrients and the influence of cover ops, with the view of evolving methods for the ntrol of wilt.

Seedlings of shisham are immune to the attack of *usarium solani*, saplings are resistant, while the adults fter the trees bloom and bear fruit) are susceptible, hen growing in close proximity in the tarai land here shisham grows naturally. In the pure planta- ons in the taungyas of Uttar Pradesh also there is o wilt of seedlings. The fungus is present throughout he soil in this region and has been described as a il inhabitant. It also causes systemic infection on he stems of siris (*Albizzia procera*) by the air-borne pores[5]. The problem of the lowering of the resistance f the host at the transition from the juvenile to the dult stage is now under investigation. Control epends on the factors which predispose the trees to he attack of the pathogen at this stage.

I am grateful to Mr. C. R. Ranganathan, president f the Institute, for suggesting the problem and ffering helpful criticism in the work. Thanks are ue to Dr. K. Bagchee, mycologist, for his advice nd interest in the work, and to Dr. W. L. Gordon, lant pathologist, University of Manitoba, Manitoba, anada, for identifying the cultures of *Fusarium olani* sent to him.

"The Case for Natural Selection"

ON my return from eight months travelling, my ttention was directed to the review of my book "Evolution in Action" by Sir James Gray (*Nature*, 173, 227; 1954). I feel I must comment on some of his statements, since they are of major concern to general biological theory.

At the outset he writes: "Darwinian orthodoxy demands implicit faith in the efficacy of natural selection operating on chance mutations. Subscribe to this and all doubts and hesitations disappear; question it and be forever lost". After saying that I state "the case for orthodoxy", he continues: "A few readers, perhaps rather pagan in their outlook, may think it a little strange that, if the case is quite so strong as they are asked to believe, it should still be necessary to argue the merits of natural selection with almost evangelistic fervour". Later, he states, "No amount of argument, or clever epigram, can disguise the inherent improbability of orthodox theory; . . . there will always be a few [biologists] who feel in their bones a sneaking sympathy with Samuel Butler's scepticism".

These allegations from one of our leading biologists demand an answer. First, I repudiate (and I am sure that other biologists will agree) the idea that there is any such thing as a "Darwinian orthodoxy" which "demands implicit faith in natural selection"—or in anything else. I venture to remind Sir James Gray of Sir Ronald Fisher's "Genetical Theory of Natural Selection". In that remarkable book, Fisher demonstrated conclusively: (1) that gradual evolutionary change, as postulated by Darwin and later established by the palæontologists, could have been brought about by selection acting on small mutations, on the basis of a particulate (Mendelian) mechanism of inheritance; but could not have been brought about on the basis of a mechanism of blending inheritance; (2) that, given the observed facts concerning heritable variations and their origin, neither orthogenesis (in the sense of inherently determined and directional variation) nor Lamarckism in any of its forms could have played any but the most trivial part in effecting evolutionary change; (3) that selection, acting upon small mutations and their recombinations, is capable of producing an extremely high degree of *apparent* improbability; and (4) that natural selection does not have to await the precise mutations needed to produce desirable adaptation, but operates on the stored variance made possible by the particulate mechanism of heredity, eliciting from it the required recombinations. (Gray's statement about selection "operating on chance mutations" obscures this essential point, and neglects the fact that the *effects* of genes are gradually adjusted by selection operating on the gene-complex.)

These are not dogmatic statements, but scientific conclusions; and the resultant neo-Darwinian or selectionist theory of evolution is no more an 'orthodoxy' than is the atomic theory of matter or the Mendelian theory of inheritance. Evolutionary biologists support it, not because they would be "forever lost" and excluded from an orthodox fold if they questioned it, but because it—and so far, it alone—is able to account for the facts.

Finally, the reason why it is still necessary, especially in a semi-popular book, to argue the case for natural selection so vigorously is that, unfortunately, a certain number of prominent biologists still publicly evince "a sneaking sympathy", to use Gray's own words, with Samuel Butler, or other vitalists or Lamarckians.

JULIAN HUXLEY

Athenæum Club,
London, S.W.1.

THAT my review of Dr. Huxley's book should be regarded as a matter of "major concern to general biological theory" is a sobering thought. It just shows how careful one must be in approaching the preserves of evolutionary genetics.

I can only say that none of the works to which Prof. Huxley refers, or appears to have in mind, gives me reason to believe that a 'conclusive demonstration' of the fact that certain things *can* happen is necessarily proof that they *have* happened. A demonstration that Dr. Huxley might conceivably make a mistake is no proof that he has, in fact, done so. Nor does a feeling of disappointment in natural selection as a working hypothesis during the past hundred years prove that biologists—prominent or otherwise—are either vitalists or Lamarckian fellow-travellers.

J. GRAY

Department of Zoology,
University, Cambridge.

APPOINTMENTS VACANT

APPLICATIONS are invited for the following appointments on or before the dates mentioned:

MANAGER (graded as Senior Experimental Officer) (with H.S.C. (science) or equivalent, and with experience in nuclear or reactor physics, and technical administration) OF THE REACTOR SCHOOL, to take responsibility for the day-to-day running of the school and act as secretary to the Management Board, arrange the course syllabus in conjunction with the lecturers and the Board, assist the physics lecturer in tutorial work and supervise the practical class associated with the school—The Establishment Officer, Atomic Energy Research Establishment, Harwell, Berks, quoting 2/103/22 (August 13).

ASSISTANT LECTURER IN THE DEPARTMENT OF PURE MATHEMATICS—The Registrar, University College of Wales, Aberystwyth (August 14).

LECTURER (grade 2) IN PHYSICAL METALLURGY—The Secretary, The University, Birmingham 15 (August 14).

LECTURER IN PHYSICAL AND INORGANIC CHEMISTRY—The Registrar, The University, Hull (August 14).

ASSISTANT LECTURER or LECTURER IN METALLURGY—The Registrar, The University, Leeds 2 (August 17).

SENIOR LECTURER IN PHYSIOLOGY—The Secretary of University Court, The University, Glasgow (August 20).

ASSISTANT LECTURER (with a specialised knowledge in algology) IN MARINE BIOLOGY, at the Marine Biological Station, Port Erin, Isle of Man—The Registrar, The University, Liverpool (August 21).

RESEARCH MICROBIOLOGIST (Scientific Officer grade) IN THE DOMESTIC FOOD PRESERVATION SECTION at the Long Ashton Research Station—The Registrar and Secretary, The University, Bristol 8 (August 21).

SENIOR LECTURER IN PATHOLOGY at the University of Sydney, Australia—The Secretary, Association of Universities of the British Commonwealth, 5 Gordon Square, London, W.C.1 (Australia, August 21).

SENIOR LECTURER IN THE POSTGRADUATE SCHOOL OF MINING—The Registrar, The University, Sheffield (August 21).

SENIOR SCIENTIFIC OFFICER (with a first- or second-class honours degree in engineering, hydro (or aero) dynamics and/or physics, or equivalent qualifications) IN THE MARINE LABORATORY of the Scottish Home Department, Aberdeen, to work in conjunction with the fisheries biologists in studying the effects of modifications of commercial fishing gear and in devising new types of modifications of gear to increase fishing efficiency, and be prepared to go to sea in the Department's research vessels or in commercial vessels—The Establishment Officer, Scottish Home Department, Room 364, St. Andrew's House, Edinburgh 1 (August 27)

PRINCIPAL SCIENTIFIC OFFICER (with an honours degree in science or civil engineering and a knowledge of applied mathematics and physics) with the Air Ministry, for work on soil mechanics, at Wellesbourne Mountford, Warwickshire—The Ministry of Labour and National Service, Technical and Scientific Register (K), 26 King Street, London, S.W.1, quoting E.41/54/A (August 28).

ASSISTANT IN BOTANY—The Secretary of University Court, The University, Glasgow (August 31).

RESEARCH FELLOWS IN EXPERIMENTAL NUCLEAR AND ELEMENTARY PARTICLE PHYSICS—The Professor of Natural Philosophy, The University, Glasgow (August 31).

LECTURER (honours graduate, with a knowledge of advanced physical metallurgy, and an interest in X-ray metallography) IN THE DEPARTMENT OF METALLURGY—The Registrar, The University, Liverpool (September 1).

LECTURER IN REFRACTORY MATERIALS in the Department of Metallurgy—The Registrar, The University, Sheffield (September 4).

ASSISTANT (with an honours degree in electrical engineering and preferably with some practical experience) IN THE DEPARTMENT OF ENGINEERING—The Secretary, The University, Edinburgh (September 11)

PROFESSOR OF ORGANIC CHEMISTRY—The Registrar, University of Adelaide, Adelaide, South Australia (September 15).

SENIOR LECTURER IN MECHANICAL ENGINEERING—The Registrar, University of Adelaide, Adelaide, South Australia (September 15).

C. H. DESCH RESEARCH FELLOW (with some research experience) IN THE DEPARTMENT OF METALLURGY—The Registrar, The University, Sheffield (September 30).

ANALYTICAL RESEARCH CHEMIST, IN THE CHEMISTRY DEPARTMENT, to develop rapid methods of analysis for trace elements in soils, waters, etc., and ANALYTICAL ASSISTANTS (2) IN THE GEOCHEMISTRY SECTION of the Geology Department—Head of the Geology Department, Imperial College, South Kensington, London, S.W.7.

ANGLO-IRANIAN OIL COMPANY STUDENT, for the study of gaseous reactions in the Chemistry Department—The Registrar, Imperial College, London, S W 7.

ASSISTANT EXPERIMENTAL OFFICER (with a qualification in physics, preferably to pass degree standard) with a research unit of the Anti-Locust Research Centre (accommodated at a Ministry of Supply establishment in Wiltshire), to assist in laboratory investigations of problems connected with the application of insecticides to flying locust swarms—The Director, Anti-Locust Research Centre, c/o British Museum (Natural History) Cromwell Road, South Kensington, London S.W.7.

ASSISTANT, Grade B (with a good honours degree in chemistry) to teach mainly physical chemistry to degree and A.R.I.C.A. standard—The Clerk to the Governors, South-East Essex Technical College, Longbridge Road, Dagenham.

ASSISTANT PROFESSOR IN CHEMISTRY—Head, Department of Chemistry, Dalhousie University, Halifax, Nova Scotia, Canada.

ENGINEERS and PHYSICISTS, Senior Scientific Officer and Scientific Officer grades (with an appropriate first- or second-class honours degree, or equivalent high professional attainments), in Royal Naval Scientific Service Experimental Establishments in the London, Portsmouth, Weymouth and Gloucestershire areas, and in Scotland—The Ministry of Labour and National Service, Technical and Scientific Register (K), 26 King Street, London, S.W.1, quoting A246/52A.

GEOLOGIST (with a second-class honours degree (upper division) in geology) with H.M. Colonial Service in Cyprus, for detailed geological mapping, more particularly of the igneous area and petrologic examination of such rock and of mineral deposits—The Director Recruitment, Colonial Office, Great Smith Street, London, S.W. quoting BCD.105/17/02.

INDEPENDENT FORECASTER (with a degree in physics or mathematics, and experience of independent forecasting, and the gener work of a city meteorological office) IN THE METEOROLOGICAL DEPART MENT, Bermuda, for duties which include forecasting for the gener public and shipping, investigation of meteorological problems, routin climatological returns and checking the work of assistant staff—T Director of Recruitment, Colonial Office, Great Smith Street, Londo S.W.1, quoting BCD.57/29/01.

READER IN THE DESIGN AND ANALYSIS OF SCIENTIFIC EXPERIMEN at the University of Oxford—The Registrar, University Regist Oxford.

SENIOR TECHNICIAN IN THE DEPARTMENT OF BOTANY—The Secr tary, Bedford College (University of London), Regent's Park, Londo N.W.1.

THE CIVIL SERVANT IN BRITAIN

THE famous report on the organization of the permanent Civil Service signed by Stafford H. Northcote and C. E. Trevelyan was presented to Parliament just over a hundred years ago at the end of February. The anniversary has been marked by numerous articles in the Press, as well as by the publication by H.M. Stationery Office of a booklet reviewing the growth and organization of the Civil Service during a hundred years and by a commemorative lecture before the University of London on February 16, 1954[*]. In that lecture Prof. K. C. Wheare dealt with the Civil Service in the constitution, with the way in which the reforms recommended in the Northcote–Trevelyan report were effected and some of their implications to-day. Prof. Wheare points out that the centenary of a modern Civil Service recruited and organized on the lines advocated in that report will not be celebrated before 1970, though with the establishment of the Civil Service Commission in 1855 there came into existence a permanent institution with a vested interest in the discovery of merit through competitive examination as a means of entry into the Service. Prof. Wheare is concerned, however, chiefly with the consequences of the adoption of these reforms; he looks upon them from outside the Civil Service and from the point of view of their effect upon the practice and efficiency of government.

The first point to which Prof. Wheare directs attention is one the importance of which has been strikingly emphasized during the past few years. The greatest change in the position of the Civil Service in the constitution since the publication of the Northcote–Trevelyan report does not consist in the removal of patronage or the establishment of permanence. Britain already had a permanent Civil Service, and the Northcote–Trevelyan reforms were aimed at ensuring that those appointed were fit to hold office. The greatest change consists in the increase in the authority of the Civil Service, and this would probably have occurred whether it was recruited by patronage, by qualifying examination or by competitive examination.

Prof. Wheare argues that, whereas a hundred years ago the principal influence in government lay with an aristocracy acting through a cabinet with the advice and consent of Parliament, nowadays the principal influence lies with a bureaucracy acting through a cabinet with the advice and consent of Parliament. This change is due largely to the growth in the extent and intensity of the State's activity and consequent increase in the powers of the Civil Service. So far as the Northcote–Trevelyan reforms have contributed, it is because when increased authority was given to the executive branch, those reforms had provided officers ready and capable of exercising power. Northcote and Trevelyan saw the Civil Service as an efficient body of permanent officers occupying a position duly subordinate to that of the Ministers who are directly responsible to the Crown and to Parliament, yet possessing sufficient independence, character, ability and experience to be able to advise, assist and, to some extent, influence those who are from time to time set over them. They saw, in fact, exactly the kind of man that, on one hand, Sir Edward Bridge depicts in his "Portrait of a Civil Servant", and Mr. Herbert Morrison, on the other, in his "Government and Parliament: a Survey from the Inside"*.

---

[*] The Civil Service in the Constitution. By Prof. K. C. Wheare (A lecture delivered before the University of London, on 16 February 1954, to commemorate the centenary of the Northcote–Trevelyan Report.) Pp. ii+34. (London: The Athlone Press, 1954. Distributed by Constable and Co., Ltd.) 2s. 6d. net.

Mr. Morrison writes frankly and with understanding about the relations between Civil servants and Ministers, and concludes with an unqualified tribute to the energy, ability, resourcefulness and incorruptibility of the Civil Service, as well as its loyalty to the Government of the day; but he fails to recognize the change to which Prof. Wheare directs attention, and the danger implicit in that change. That may well be because, although Mr. Morrison is expressing an inside view, it is one from the Ministerial angle. He recognizes fairly enough the danger to the public interest that lies in overworking the higher Civil servant and that, like other senior professional men and women, senior Civil servants, though loyal, may not be quick enough in accepting or adapting themselves to new ideas. He has not quite recognized the 'statesman in disguise' of Sir James Stephen; the latter, admitting the evils of patronage and the need for a better-educated Civil servant, nevertheless thought that the man at the top of the examination list would be too good for the Civil Service.

Prof. Wheare puts besides Sir James Stephen's comment of a hundred years earlier the official description, by the Civil Service Commission, of what it expects to-day of a successful candidate for the Administrative Class, and of what he may expect of the Civil Service. He is "concerned with the formulation of policy, with the co-ordination and improvement of government machinery, and with the general administration and control of Departments. The ideal candidate would possess intellectual ability of a high order, and the ability to discern and analyse the essentials of complicated questions, and to express himself with lucidity in speech and writing. He would be able to get on well with all kinds of people, be adaptable, far-sighted and persevering, and have enough strength of character and leadership to hold his own, take decisions and exercise responsibility. He would have enough practical imagination to enable him to devise, in broad outline, workable plans for dealing with an unprecedented situation. Above all, he would need judgment and commonsense".

Before we consider the implications for to-day of a Parliamentary bureaucracy, which has in fact, contrary to some predictions, attracted a high proportion of the ablest young people of successive generations, and perhaps an excessive proportion, one consideration emphasized by Prof. Wheare should be noted. He believes that an important factor in attracting so many of the ablest young people from the schools and universities has been the persistence of the tradition that service to the State is an honourable profession. Prof. Wheare wonders whether that tradition is now as strong as it was. Certainly the tendency of a certain section of the Press to denigrate the Civil Service on any possible pretext, though not countenanced either by Parliament or Ministers, does not help to maintain the tradition. None, however, who is concerned to see that the task of government is well and efficiently discharged can be indifferent to the firm maintenance of the great tradition that has made the Civil Service a pre-eminent profession in Britain.

Prof. Wheare has no hesitation in affirming that to-day we need (and in large measure we get) in the higher Civil Service not only skill in the management of public affairs but also the wisdom, vision and imagination which are the mark of statesmanship, and that it should be the constant anxiety of those responsible for recruitment to see that our methods of selection, training and promotion attract and retain persons possessing such qualities. But he adds two qualifications. First, although in one sense it is true that adoption of the principles of the Northcote–Trevelyan report both took party politics out of the Civil Service and the Civil Service out of politics, a Civil servant's work is carried out in the midst of party politics. Everything he does is done in the name and upon the responsibility of a Minister who belongs to a party, and anything he does may have party consequences for his Minister and, at times, for the Ministry as a whole. In formulating policy, for example, a higher Civil servant is advising and assisting a Minister not only to carry through a policy which is that of a political party with a majority in the House of Commons, but also to defend that policy against the criticisms and attacks of the Opposition.

Accordingly, as Prof. Wheare points out, a higher Civil servant requires a political sense; and in saying this he has put his finger on one of the causes of the mismanagement which has aroused such widespread concern over the Crichel Down report. The essential question in that unhappy episode is what is the public interest, and how and by whom it should be determined. Those questions cannot be answered even by men of the most impeccable integrity or intellectual ability without political sense. Lacking that sense, the extreme delicacy of the position of the Civil servant, of which Prof. Wheare reminds us, is fatally disturbed; but it is equally true that the maintenance of that delicate position depends as much or more upon a correct attitude on the part of Ministers and Members of Parliament towards Civil servants as it does upon the attitude of Civil servants towards them.

On this question of the relations between a Minister and his Department and between Parliament and the Civil Service, one would have welcomed much more comment from one writing from inside, like Mr. Morrison, particularly from one who possesses such a sense of the rights of the House of Commons as a whole and of the responsibility of the Government to the House rather than to a political party, and who recognizes the danger that party discipline may be overdone. A concrete episode like that of Crichel Down throws a more searching light on the weaknesses of our Parliamentary institutions and the changes required to adapt them effectively to the needs of to-day than Mr. Morrison's generalizations. Indeed, Prof. Wheare's second proviso is more relevant to the Crichel Down episode than any passage in Mr. Morrison's book. "Civil servants," he writes, "may be statesmen in disguise, but they must not be Ministers in disguise."

---

* Government and Parliament: a Survey from the Inside. By Herbert Morrison. Pp. v+363. (London: Oxford University Press, 1954.) 21s.

Prof. Wheare recognizes that it is possible that Civil servants accustomed to act on behalf of or in the name of Ministers may be tempted at times to think and act as if they were Ministers. He is, however, convinced that it is still an axiom in the Civil Service that no matter how much a Civil servant may act on behalf of his Minister, he must never forget that his Minister bears the responsibility, and for justification of that confidence Prof. Wheare points to the evidence of 'question time' in the House of Commons. The remedy for arbitrariness and errors of judgment such as the Crichel Down report has exposed lies, in Prof. Wheare's view, in stronger Ministers and a more independent and vigilant House of Commons rather than in weaker Civil servants.

Now, although the position of the scientific Civil servant or of the scientific expert in general is nowhere specifically discussed by Prof. Wheare or even by Mr. Morrison, in spite of a brief recapitulation of steps he took, as Lord President of the Council, to improve the arrangements for scientific advice, the nature of the relations between Ministers and their advisers is of vital importance to the participation of the man of science in the task of government. The first condition for effective relations is mutual confidence, and here the question of the relations between Government and Parliament and the dominance of a political majority are more important than Mr. Morrison suggests. Civil liberty depends on Parliament never becoming the instrument of a single class. It also depends on Ministers seeking to further primarily the public interest, and not simply that of a political party which may or may not even represent the majority of an electorate, however much the Ministerial conception of the public interest may be influenced by political ideas. The expert must at least have some assurance that the advice he renders in his particular field will be fairly considered by those competent to appreciate its significance, and that it will be evaluated objectively along with the other factors involved in the situation.

It is because there have been frequent indications in recent years of the plain disregard of facts and of deteriorating standards of Ministerial conduct that the situation cannot be regarded with the satisfaction that Mr. Morrison's book implies. Some five years ago, we commented on two instances which seriously prejudiced the self-respecting association of the scientific and technical expert in the task of government (see *Nature*, 164, 1103; 1949). Others are to be found since in such matters as fuel policy, broadcasting and television, national parks, and in scientific and industrial research as well as in technological education.

The first step to establish full confidence and proper relations between Ministers and their Departments and advisers, whether scientific or otherwise, is firmly to re-establish the rule affirmed by the Newton National Civil Aviation Consultative Committee in 1948, that no man should be judge in his own case. That indeed is the first thing that should have come out of the discussion in Parliament of the Crichel Down report if any public confidence is to be felt that there will be an end to departmental high-handedness. Failure to elicit such an assurance would have dealt a fatal blow to the essential spirit of the British constitution as well appears from Sir Alfred Denning's lectures, "The Changing Law" (Pp. 122. (London: Stevens and Sons, Ltd., 1953.) 10*s.* 6*d.*). Nor will confidence be restored by an investigation by the Civil Service Committee under Sir Edward Bridge's chairmanship—a Committee which *ipso facto* infringes that principle.

Next, it has to be admitted that the efficiency and possibility of government depend upon removing a great many decisions from the range of popular choice. When the size of a Department compels extensive delegation of power, responsibility must go with it; otherwise petty tyranny and bureaucracy will replace democracy and government by consent. The doctrine of Ministerial responsibility requires re-examination in the context of situations in which it is clear that advice has not been tendered and considered at anywhere near Ministerial level.

This, then, and the indication of the right and force of public criticism were the first things required of Parliament in the Crichel Down debate: they transcend in public importance even any steps taken to rectify an injustice. But of equal importance are the questions what is the public interest, and how and by whom should it be determined. Manifestly, the assumption that every public servant has a primary concern for the public interest and can be trusted without inquiry to pursue it can no longer be accepted. It never has been accepted for the scientific or technical expert, and it is perhaps all to the good that it should now be shown so plainly that the administrator stands on the same level.

It is no longer possible to ignore the evidence which has accumulated since the War, especially over land for the Services and other government departments or public corporations, that a government department is not necessarily any sounder judge of the public interest than anyone else. Decision as to what is the public interest can only be made at ministerial- or even at cabinet-level. If the cabinet fails to formulate the broad lines of policy and it is impracticable or impossible for a Minister to master all the facts and details in the multitude of cases in which this principle would reserve to him the final decision, we have to evolve some further practical means, as Sir Alfred Denning indicates, of providing that the issues are surveyed impartially at some stage by a competent but wholly independent person.

That is the vital principle at stake and Parliament has no greater responsibility than to insist on seeing that the means necessary to serve it are implemented without delay. It affects almost every aspect not only of the impact of government and of the Civil Service on the lives of the individual citizen, but also of the participation of the man of science and the technical expert in the task of government. To them it would offer the assurance, not yet wholly theirs, that the advice they tender within their own particular field of competence and knowledge would be considered intelligently and impartially along with that given by other experts concerned, and evaluated in the light of the situation as a whole. More they are not entitled, nor do they wish, to claim. But such measures for terminating the power of a government department or any other body to judge its own cause, and giving the assurance of impartial consideration of all issues and fair treatment of individuals, would have as one further consequence the placing of the scientific and technical expert more nearly on an equality with the administrator. Their importance justifies the hope that they will be formulated in no party spirit, but with full appreciation of how much is at stake—no less than the stability of our Parliamentary institutions.

In the debate in the House of Commons on July 20, the doctrine of ministerial responsibility was supported not only by the resignation of Sir Thomas Dugdale but also on all sides of the House. There was some general appreciation of the complexities that arise in applying that doctrine to-day. More might have been said on the question of the public interest; but the swiftness with which Sir John Woods's Committee has reported to the Prime Minister and the forthrightness of the report on this point warrant the hope that these issues will receive ample and urgent attention. "In the present times," says the report, "the interests of the private citizen are affected to a great extent by the actions of Civil Servants. It is the more necessary that the Civil Servant should bear constantly in mind that the private citizen has a right to expect, not only that his affairs will be dealt with effectively and expeditiously, but also that his personal feelings, no less than his rights as an individual, will be sympathetically and fairly considered." It is a prime responsibility of Parliament to see that that doctrine is never forgotten or ignored.

EXPERIMENT IN THE POPULARIZATION OF SCIENCE

Die Welt der ungewohnten Dimensionen

Versuch einer gemeinverständlichen Darstellung der modernen Physik und ihrer philosophischen Folgerungen. Von Prof. Arnold Hildesheimer. Pp. 368. (Leiden: A. W. Sijthoff's Uitgeversmaatschappij N.V., 1953.) 17.90 Dutch florins.

TRANSLATED into English, the title of this four-hundred-page volume by Prof. Arnold Hildesheimer is "The World of Unaccustomed Dimensions". Its scope is, however, more closely defined by the sub-title: 'Versuch' of a popular presentation of modern physics and its philosophical implications. 'Versuch' could mean one of two things: 'attempt' or 'experiment'. Regarding the work as an attempt, the reader is immediately captivated by the enthusiastic earnestness of the author's endeavour to raze the mathematical fortifications separating the 'expert' from the interested layman, in order to open for him a view into the fundamental concepts of physics and all their enjoyable or threatening technical consequences with which modern man has to live. The author points correctly to the abyss which isolates the scientist from the masses. Any attempt to bridge this gap will be greatly appreciated by anyone living on either side of the fence, and throughout the book the honesty of this attempt can be recognized.

In four main parts, the author tries to encompass the essential ideas in physics as they have evolved during the past five centuries. In the first part, dealing with "The World of Medium Dimensions", we get a rapid treatment of classical mechanics, the field concept, matter, gravitation, energy, causality, statistics, entropy, the atom, optics and Maxwell's theory of electromagnetism. The theory of relativity is introduced in the second part: "The Macrocosm". Both special and general relativity are discussed, and the author tries to familiarize the reader with four-dimensional geometry and Riemann spaces. Part 3 turns to "The Microcosm". Quantum and wave mechanics are described in terms of the work of the great leaders, Planck, Bohr, de Broglie, Schrödinger and Heisenberg, and the duality wave-particle is pointed out. In the fourth and final part, "Consequences for the Theory of Knowledge", the author summarizes and integrates the concepts presented and speculates about the significance of these thoughts for the ultimate issues like fate, free will, *existentia et essentia*. A bibliography of more than sixty popular and scientific books on these subjects and eight appendixes plus a complete index conclude the book. On every page the author's admiration for the giants is evident, and wherever it is feasible he allows the great men of science to speak in their own words.

No doubt this work represents an honest attempt to relieve the layman from his 'sacred awe' when he is exposed to the innermost of the magic circles of science. But the question is: What is the result of the work as an experiment? In other words, how successful has the author been in explaining to the layman the essential pillars of scientific thought? How much does he contribute to the clarification of complex ideas like curvature of space, entropy and probability, the uncertainty principle and similar concepts? This brings us to the method the author uses throughout the whole book: the method of comparison.

Almost every page contains one or more examples in which a physical situation is 'explained' by a comparison with simple everyday-life experiences. If some of these comparisons contain words which perhaps are not in the vocabulary of the reader, the first-order comparison is explained by a second-order comparison with an even more simple everyday-life experience—and so on. This leads to a hotchpotch of armchairs, gravitational fields, pregnant mammals, cosmologies, twirling sticks, cannons, Maxwells, horse carriages, Jacks and Jills, red shifts of spectral lines, flying bullets, pilots jumping off planes, potential barriers, Riemann spaces and people invited to parties. It finally becomes so complicated that not only does the reader lose completely the thread of what had to be explained in the first place, but the author is also deeply lost in an ocean of n-th order explanations. Furthermore, it is doubtful whether an everyday experience can suffice to serve as an analogy to atomic or cosmic situations. If that were the case, quantum mechanics and general relativity could be reduced to classical mechanics. The poetic comparison of a beautiful girl with a rosebud is perfectly legitimate if one knows both. But it is doubtful whether somebody who has never seen a girl would recognize one as such, if he only knows that they are like rosebuds.

It can be argued that the interested layman may suddenly grasp the idea of the metric tensor if he is told that if one invites people (stars) to a party (universe) and they have to bring chairs (gravitational fields) along, it may eventually become so crowded that a newcomer may indirectly cause a distant guest to move his chair (the distribution of the masses in the universe defines the geometry of the universe—pp. 175 and 185). But it cannot be argued that the author's statement "... the formula $v = \lambda\nu$ tells you, as you know, that the velocity of a wave is solely dependent upon the medium in which it is propagated. ..." is wrong (p. 99). Another example: "... If one observes the light of a body in its spectrum and recognizes that this spectrum has shifted to the red, one has proof that the frequency of the light is reduced, i.e., the motion of the body has been retarded. And indeed that is observed if one views in the spectrum the β-rays emitted from a rapidly moving radium atom.... This redshift of the spectrum is one of the proofs of Einstein's theory of light" (p. 149). This statement is not only wrong, it is nonsensical, like "the causal law of gravitation" (p. 305). Misinterpretations of the type of 'near-truths' occur frequently in the book. This is a consequence of the hopeless attempt to describe the rules of chess by those of noughts and crosses. Readers who may look for some hints in the field of nuclear physics will be disappointed. The word meson is mentioned only once, and the all-out effort of modern physicists to determine the structure of the nucleus is not mentioned once.

If this honest attempt at a popular presentation of modern physics and its philosophical implications is regarded as an experiment in popularization, I must regretfully conclude that it is a failure. But the question remains: Can science be popularized at all?

Heinz Von Foerster

MODERN FOOD HYGIENE

Food Poisoning and Food Hygiene

By Dr. Betty C. Hobbs. Pp. x+174. (London: Edward Arnold and Co., 1953.) 14s. net.

This book by Dr. Betty C. Hobbs should be read by all those interested or engaged in the production and handling of food. It will also be found of great use to those who are engaged in the administration of the new Food and Drugs Act in its present and anticipated amplified form.

At any time the contents of the book would be a valuable contribution to the literature of the subject; but its publication now enhances its value. As its title implies, it deals with the subject in two sections—food poisoning and food hygiene—and it is written in a manner which makes it easily understood by others than specialists. There is a tendency to deal with the subjects rather more from the academic than the practical aspects, and only those who have experienced the great difficulties of administering the simple rules of food hygiene will grasp how practically impossible it will be to carry out *in toto* the recommendations in Dr. Hobbs's book, admirable as they are.

The simple explanations and clear illustrations in the section dealing with food poisoning should convey to the reader something of the complexity of the subject, and the manner in which these micro-organisms form the toxins. Until very recently, *Clostridium welchii* were not regarded as falling into the class of food-poisoning bacteria, but, according to the table on p. 36, they were the cause of the outbreak of twenty cases out of a total of thirty-three. In the pages following these tables, explanations are given of the history of these cases, and these need to be read in the light of the second section of the book, dealing with hygiene. In this, there is sound advice, which, if it can be followed, should do much to minimize these outbreaks; but it is not all easy to carry out.

The female's head-covering, illustrated on p. 85, is not effective; experience has shown that the hair must be completely covered. The idea of regular educational talks on personal hygiene, although by no means new, is an excellent one; but it will be found that, in order to secure a full audience, such lectures have to be delivered during working hours and, therefore, interfere with production. It is a pity that Dr. Hobbs fails to direct attention to the hazards attached to the cafeterias of the help-yourself type, in which the unwrapped food is exposed to fingering, coughing and sneezing by hundreds of persons every day. Perhaps greater attention could be focused upon the cause of contamination of foods in retail shops, due to exposure, unclean knives, soiled aprons, etc., and the fly menace.

Dr. Hobbs is to be congratulated upon the excellence of her book. It should certainly enjoy a wide circulation, and it will doubtless prove of great use to the food industry.

Osman Jones

EXPERIMENTAL PLANT MORPHOLOGY

Entwicklungs- und Bewegungsphysiologie der Pflanze

Von Dr. Erwin Bünning. Dritte auflage. (Lehrbuch der Pflanzenphysiologie, Zweiter und Dritter Band.) Pp. xii+539. (Berlin: Springer Verlag, 1953.) 49.60 D. marks.

Experimental plant morphology has recently undergone a revival, especially in Germany, and there are flourishing research schools under Richard Harder in Göttingen and Erwin Bünning in Tübingen. Indeed, Bunning's monograph, which is here under review in its third edition, is a monumental summary of the subject, and a valuable source-book of facts and ideas.

Particularly ideas. For if there is one criticism of this book it is that the documentation of facts is inadequate and the distinction between established facts and illuminating speculation is not always clear. The expression "dass wird man so und so erklären können" is admirable when the speaker can be cross-questioned about the authenticity of his facts: it is exasperating when the reader has to guess whether this *is* the explanation, or only whether it *might well be* the explanation. A symptom of this failing is the paucity of references (though there are many more than there were in the second edition) and the absence of an author index.

The book has been enlarged by some seventy-five pages, mostly by the interpolation of new paragraphs. Its scope remains as it was: chapters on growth and cell division, differentiation (with a considerable amount of new material), plant movements, and the effects of external stimuli on movement and development. Bünning's own views on photoperiodism and endogenous rhythms are well summarized, together with recent experiments which appear to corroborate his hypothesis.

In a book which covers such a wide sweep of knowledge any critic can find omissions; a few of them are mentioned here only in the hope that they may be repaired in a fourth edition. The discussion of the relation between respiration and growth (pp. 84–91) is not convincing, and needs fuller and more critical treatment. The section on weed killers (p. 132) might well be expanded, for it omits so much that it is not easy to understand the residue. The section on stomatal movement (p. 429) is not up to date. Vernalization (p. 473) receives a scant three and a half pages, which seem inadequate in a book which specializes in developmental physiology. Finally, one is bound to say that the style suffers from a Teutonic turgidity, and the index is not nearly full enough for an important work of reference of this kind.

However, these are criticisms of detail, and they do not detract seriously from the massive erudition of the book and the fecundity of its ideas. It cannot be denied that the most powerful weapons in plant physiology are the techniques of physics and chemistry, and that sooner or later every physiological problem needs these weapons for its solution. But as more mature physiological problems reach the stage which requires the chemist's technique, new problems emerge from the experience of naturalists and gardeners and agriculturists; and these can be tackled by the techniques of biology. Anyone who doubts such an assertion as this has only to read Bünning's book. For the English student, who is likely to hear all too little of this fascinating field of physiology, the book has a great deal to offer, and it is to be hoped that sooner or later an English translation will be available.

E. Ashby

THE RARER METAL, ZIRCONIUM

Zirconium

By Dr. G. L. Miller. (Metallurgy of the Rarer Metals No. 2.) Pp. xviii+382. (London: Butterworths Scientific Publications; New York: Academic Press, Inc., 1954.) 45s. net.

This book is the outcome of its author's desire to collate the information on zirconium which has been accumulating so rapidly during the past few years. Dr. G. L. Miller has been in an advantageous position to do this by reason of his own wide experience and also because of his visits to workers in the same field in the United States. As a result of his work, he has written this text-book and reference volume which will appeal to every chemist and metallurgist interested in zirconium. There are eighteen chapters, the first of which opens with the history and the occurrence of zirconium, its consumption and uses both as metal and alloys and, naturally as a refractory material. The treatment in all cases is as thorough as the available data will permit, and the very carefully assembled bibliography at the end of each chapter is up to date and of notable dimensions. Methods of extracting the metal and the preparation of pure zirconium compounds are discussed in some detail, in particular the separation of hafnium and zirconium from one another. Earlier and more recent production methods are described, notably the van Arkel or iodide process and the Kroll processes in which purification and reduction are combined. Reduction of the tetra-chlorides of titanium and zirconium and the arc-dissociation of halides, and also methods of electrodeposition from fused salts as well as from aqueous and non-aqueous solutions, receive attention.

Following a general account of the structure, crystallographic, atomic and nuclear characteristics, attention is given to physical properties. Thermal, electrical, optical, thermionic and magnetic properties are reviewed and illustrated by graphs. There are two chapters on the mechanical properties of zirconium metal, and on zirconium alloys at room and at elevated temperatures. In this latter chapter, alloys of some twenty-four elements are included, not counting the zirconium alloys with oxygen and nitrogen which receive separate treatment in the following chapter. The chemical and corrosion resisting properties of the metal and its alloys and their resistance to the action of liquids in general and to some of the concentrated mineral acids as well as a range of organic acids is illustrated by a series of useful tables. Probably the most valuable and generally useful chapter in the book is that on alloys of zirconium, in which first the alloying theory and its application to zirconium is discussed on a theoretical basis and then the practical results of comparatively recent investigations of binary systems involving zirconium are reported with phase diagrams of many of the binary alloys. This chapter has a bibliography involving more than eighty references and covering all the contemporary useful contributions to the subject. The chapter on melting practices discusses those types of furnace that can be applied to zirconium and is followed by an account of fabricating the metal by rolling, extrusion and other techniques, in which brazing and soldering are not lost sight of and attention is directed to the fact that zirconium has superior wetting and very good bonding qualities.

The powder metallurgy of zirconium has its own chapter in which the conclusions of H. A. Hausner and his colleagues at Sylvania Electric Products, Inc., Bayside, Long Island, New York, that zirconium is readily fabricated by powder methods are confirmed. The most important part of the chapter deals with the preparation of zirconium powder. The last chapter covers special compounds such as the nitride, the carbide, the boride and the silicide, but there is a valuable appendix dealing with some eleven methods of preparing material for metallographic examinations.

The usefulness of the chapter bibliographies is increased by the addition of a final black numeral or numerals to each reference denoting the page upon which the reference is cited, a distinct advantage to the busy worker who quickly wants to find where the reference appears and its specific terms.

H. W. Greenwood

Introduction to Solid State Physics

By Prof. Charles Kittel. Pp. xiii+396. (New York: John Wiley and Sons, Inc.; London: Chapman and Hall, Ltd., 1953.) 56s. net.

THIS book forms a valuable addition to the literature on solid-state physics, and can be strongly recommended to those engaged in the preparation of university honours degree courses in this subject. The range of subjects included is wide: the sixteen chapters deal with crystallography, elastic, thermal, electric and magnetic properties, the electron theory of metals, and crystal imperfections, problems for the student being suggested at the end of each chapter. Prominence is given to relatively new subjects such as ferroelectricity and antiferromagnetism.

The emphasis is almost entirely on theory; experimental methods are referred to only briefly. A high standard of theoretical ability is expected of the reader, and occasionally the author seems to have taken a delight in starting from unnecessarily general premises. For example, he defines the unit cell of a crystal as a polyhedron, whereas it is always taken to be a parallelepiped; and in equation 1.12 is it fair to the student to allow the same symbol—i—to have two different meanings, clear as these may be to the expert?

In fact, the first chapter, on X-ray crystallography, is the weakest in the book, and contains several statements that would not be accepted in crystallographic circles. For example, on p. 9 symmetry elements called rotation-reflexion axes are introduced; they should be rotation-inversion axes. It is hoped that in future editions of the book, Chapter 1 will either be largely rewritten or will consist mainly of references to standard crystallographic text-books.

Yale University Publications in Anthropology

No. 49: Excavations at Wari, Ayacucho, Peru. By Wendell C. Bennett. Pp. 126+12 plates. No. 50: On the Excavation of a Shell Mound at Palo Seco, Trinidad, B.W.I. By J. A. Bullbrook. Pp. 114. (New Haven, Conn.: Yale University Press; London: Oxford University Press, 1953.) 3 dollars.

THIS volume is made up of two papers, each dealing with a particular aspect of American archæology. The first is a posthumous publication of Prof. Wendell C. Bennett, whose premature death last summer deprived South American archæology of one of its most notable scholars. It describes his excavations, in 1950, at an extensive habitation site, spelt variously Wari and Huari, in the little-known but important highland basin of Mantaro, which lies just north-west of the Cuzco basin. The chief remains at Wari are contemporary with the Classic Period at the well-known ceremonial site of Tiahuanaco in Bolivia, with which they have many features in common; but they include a pottery style more closely related than any at Tiahuanaco itself to the Coastal Tiahuanaco style which has such a wide distribution on the coast. Prof. Bennett discusses fully the relationships between the various Tiahuanacoid sites and makes suggestions as to the nature of the contacts between them.

In 1919, Mr. J. A. Bullbrook excavated a shell mound in southern Trinidad with official support, and the resulting material and the report went to the British Museum. Mr. Bullbrook is a geologist with considerable archæological experience, and his work was done very carefully; for various reasons it was not published at the time, and for many years afterwards he got little encouragement. He continued to live in Trinidad, and when members of Yale University began to work on the West Indies about fifteen years ago, his researches came to their notice. Subsequent work, mainly by Dr. Irving Rouse of Yale, has confirmed his results, and Dr. Rouse has considered it worth while to edit the report and publish it in spite of the long interval since it was written. The Palo Seco mound was inhabited at two periods in Pre-Columbian times, separated by a short interval, by people who lived on shell-fish, fish and game, probably with some cultivated plants, although there is no direct evidence of agriculture. There are few artefacts other than pottery, which forms the basis for the definition of one stage, the Palo Seco style, in a succession of rather similar types established by Dr. Rouse. The British West Indies have been very much neglected by archæologists until recently, and most of the modern work has been done by Americans. Mr. Bullbrook's pioneer work, which satisfied the exacting standards of the school at Yale, is much to his credit.

G. H. S. BUSHNELL

Advances in Electronics

Edited by L. Marton. Vol. 5. Pp. xii+420. (New York: Academic Press, Inc.; London: Academic Books, Ltd., 1953.) 9.50 dollars.

ENGINEERS and physicists will again be indebted to Dr. L. Marton for bringing together further review articles in this Vol. 5 of "Advances in Electronics". A wide field of specialization is represented, the most topical of which are colour television and junction transistor applications. Other subjects include thoria emitters, solid-state luminescence, detectors for visible and infra-red radiation, β-ray spectroscopy and modern vacuum pumps. The articles are authoritative, clear, well illustrated and contain abundant references; the cumulative index includes earlier volumes. This book is to be highly recommended.

L. JACOB

Explorers of the Pacific

European and American Discoveries in Polynesia. By Te Rangi Hiroa (Peter H. Buck). (Bernice P. Bishop Museum Special Publication 43.) Pp. viii+126. (Honolulu: Bernice P. Bishop Museum, 1953.) 1.75 dollars.

THIS is a posthumous work which arose apparently out of Sir Peter Buck's monograph, "An Introduction to Polynesian Anthropology". It purports to be an important anthropological document, "for it describes the early contacts of Polynesians with Europeans and Americans, hence provides a picture of the setting in which the culture change of modern times had its origin". What it does is to give a brief account of voyages in the Pacific between 1486 and 1849 in chronological order and without any real attempt to estimate their importance. Some of the brief judgments on the explorers give a wrong impression: for example, that Drake "fooled" the Spaniards by not returning via Magellan's Strait, or that Cook, on his third voyage, "dispelled the theory of a northern passage into the Atlantic". The list of "literature cited" is incomplete as a bibliography, and, although a great many islands are mentioned in the text, there is only one small map on which the main groups of islands are marked. This book has its use as a brief guide to voyages in the Pacific; but is too brief to make any serious contribution to our understanding of any of them.

J. N. L. BAKER

NATURE PROTECTION IN THE NEAR AND MIDDLE EAST

DURING June 3–9 a conference on the conservation of Nature in the Near and Middle East was held at Beirut, organized by Prof. F. Ghosn, president of the Lebanese Society of the Friends of the Trees, and Mr. W. E. Purnell, director of the Unesco Middle East Scientific Co-operation Office. The conference was attended by scientists and others from Cyprus, Egypt, Greece, Iraq, Jordan, Lebanon, Syria and Turkey. Dr. E. H. Graham, director of plant ecology, Soil Conservation Service, United States Department of Agriculture, attended from Washington, D.C., and Lieutenant-Colonel C. L. Boyle went from London on behalf of the Society for the Promotion of Nature Reserves and the Fauna Preservation Society. Many of the participants are actively engaged in conservation problems in their own countries and, at the conference, had an opportunity to exchange opinions and discuss experiments. After a short general discussion, study groups were formed to consider separately soil, flora, fauna and education.

The discussions of the soil and flora groups showed that, although great damage had been done to the forests of the Near and Middle East, they had not been utterly destroyed. M. P. Ballot, head of the French Agricultural Mission to the Lebanon, said that they had only just realized the continued existence in the Anti-Lebanon mountains of a juniper forest of perhaps a million trees; furthermore, experiments had shown how extraordinarily quickly vegetation could re-establish itself when it was protected from grazing. A distinction can be drawn between the damage done by the grazing of sheep and of goats; whereas trees can grow fairly quickly beyond the reach of browsing sheep, goats, as was shown by a photograph of them feeding high in an oak tree, can reach almost anything.

The flora group pointed out that in much of the area the climate is not sufficiently arid to explain the lack of vegetation; but even where the rainfall is adequate, the destruction of the plant cover has resulted in the water being lost by immediate run-off, deep percolation and evaporation. Moreover, it is not only the quantity of plants which matters. Where grazing is heavy, perennial grasses with spreading root systems, which bind together the soil, build up humus beneath the surface and retain moisture, are replaced by annual grasses which do nothing to resist erosion. Similarly, forests are replaced by thorny shrubs with tapering roots, which do little to conserve the soil. The annuals and the thorny shrubs survive because they can resist grazing.

It is fully understood that complete elimination of goats is not possible, for they play an important part in the economy of the area; but their number must be radically reduced. Mr. Y. Salti, director of forests, Jordan, explained how goat control is effected in his country. When a considerable majority in a village vote against goats, they are restricted to three tethered goats per family. In practice, the reduction in goat population is not easy, for it is the shepherds who own not only the goats but also the village rifles.

The chief factor in the destruction of the forests has been the demand for fuel; but preservation is linked with the economic betterment of the people. A man blamed for cutting good, bearing olive trees said, "What am I to do? I have a large family and absolutely nothing with which to provide them with food, but the immediate value of these trees".

Wood is cut for many purposes besides domestic burning—for charcoal burning, for firing of bakeries and lime kilns. That these can be brought under control has been shown by the example of Cyprus. Oil is the alternative to wood, but for domestic use oil alone is of little value. The production of a really cheap crude-oil stove would be a major step towards the prevention of soil erosion. The solar stove, which cooks by the sun's rays, is considered to be a possible answer to the problem, but so far its cost has been prohibitive.

The fauna study group, working under the chairmanship of Prof. C. Kosswig, of Istanbul, were told how the recent killing of pelicans on Lake Marmara has resulted in such competition for food among young carp that their growth has been retarded and none has reached full size. A very interesting report came from Cyprus, where natural regeneration of the forests of *Pinus nigra*, confined to altitudes above four thousand feet, has failed. In spring, when the warm khamsin wind blows, the cones open and discharge their seeds, which, clearly visible on the snow, are eaten by hordes of migratory finches. Possibly destruction of hawks, which controlled the number of finches, has led to the failure of the natural regeneration of the pines.

Egyptian scientists directed attention to the dangers inherent in the excessive use of poison sprays and insisted that nature reserves should contain as many kinds of habitat as possible, including ponds for the protection of water insects. They recommended special protection for the desert monitor and the four large lizards of the genus *Uromastix*, the only herbivorous lizards; these are in danger of extermination because they are being used in laboratory work, for which smaller lizards would do equally well. Stress was laid on the importance of instruction in the mosques, for the fellaheen are very responsive and have great faith in their religious teachers.

Among the recommendations of the fauna group was that a questionnaire should be sent to appropriate schools in Turkey, to discover the status of the rare monk seal, which still appears every year on the coasts. Similar methods in other cases have produced good results. An investigation into the status of the rock hyrax in Lebanon, with the view of its preservation, was also suggested. Many mammals were recommended for protection—for example, the leopard, lynx and jungle cat in Turkey and the wild ass and addax in Egypt, where they still exist on the Sudan border. Reserves for wild life were recommended at Kammouha in the Lebanon, in the province of Lattakia in Syria and at Wadi-el-Natroun and Wadi-el-Assioti in Egypt.

All governments were advised to safeguard rivers against pollution. Though rivers in this part of the world may not yet have been affected, it is a danger to be guarded against as industrialization progresses. Destruction of fish by poison and explosives will ever be stopped until fish wardens are appointed nd the public instructed in conservation.

During a visit to the best-known group of cedars in ebanon, it appears that grazing in their vicinity has een stopped; nevertheless, there was little sign of egeneration, prevented perhaps by human trampling. The conference was shown research work at the ranco-Lebanese agricultural college at Ryak and, n the coast, research into the fixation of sand-dunes y grasses backed by plantation of the umbrella pine, *Pinus pinea*.

A full report of the conference will be prepared by he Unesco Middle East Science Co-operation Office, nd suggestions for the implementation of the esolutions sent to appropriate bodies.

C. L. BOYLE

PROGRESS OF CANCER RESEARCH

THE investigations under way at the research centres financed by the British Empire Cancer Campaign are described in its thirty-first annual report*; incidentally, it may be remarked that the Campaign's income in 1953 was £350,000, which is about the cost of one air liner.

The different lines of work surveyed in the report can be grouped into those dealing with: (*a*) carcinogenesis, cytotoxins, nucleoproteins (in the laboratory light-heartedly referred to as 'secret-of-life studies'), tissue culture and immunology; (*b*) radiotherapeutics and radiobiology; (*c*) clinico-pathology.

The explanation for the ominous increase in lung cancer in the past two or three decades continues to be the principal theme of general interest in cancer research.

Emphasis has now shifted slightly from cigarette smoking as a very important factor in the causation of the disease to the influence of atmospheric pollution. This does not mean that experiments on the tobacco factor have ceased; far from it, for at several laboratories mechanical smoking installations have been set up with the aim of obtaining in quantity the components of tobacco smoke and testing them on animals. One of the main problems is, of course, to find an experimental tissue with the same sensitivity as human lung.

Tobacco extracts reinforced by croton oil have failed to induce tumours when applied to mouse skin. The complementary experiment when the extracts were tested as possible co-carcinogen for dimethylbenzanthracene also gave negative results.

The inhalation of carcinogen-loaded charcoal has not induced lung cancer in a single mouse of eighty-five which survived a minimum of six months, although the same charcoal suspension was actively tumour inducing when injected subcutaneously. It is suggested that the negative result is due to the carcinogen not reaching the parenchyma but being rapidly removed from the bronchial tree. This explanation could be confirmed by the fluorescence microscopy of frozen sections.

At the Glasgow centre it was found that application of crude oxidized nicotine to the skin of fourteen mixed-stock mice gave adenomata of the lung in seven of the animals. This remarkable result seems to have induced a hypercritical state in the investigators, Schontal and Head, for they say, "However, these results may not be significant, and should be repeated using a different strain of mice as well as other species of animal".

The part played by industrial and domestic smoke in the causation of lung cancer is discussed in Sir Ernest Kennaway's review of atmospheric pollution in Iceland, Britain and Norway.

"Great Britain has stores of coal and iron which have been the source of vast wealth, and of many other consequences. Iceland, which has no such resources, and has not even abundance of any kind of fuel except peat, has a history, and a degree of civilization which all other countries must admire, without industrialization or poverty as we understand these things in many countries of Europe and America. Hence data from a country such as Iceland are of great value for comparative purposes. The Industrial Revolution which in the earlier part of the 19th century converted England, by the utilization of coal and iron, from an agricultural to an industrial country, caused an enormous increase in atmospheric pollution. Obviously this factor cannot, by itself, account for the sudden increase of deaths attributed to cancer of the lungs which occurred a century later, in the 1920's, when the output of smoke was declining. Recently the greater part of this increase, and the higher incidence of this form of cancer in towns, has been ascribed to tobacco, but a possible contributory effect of the suspended matter of town air cannot yet be excluded finally. Iceland provides the example of a country where bronchial cancer is rare, the general consumption of tobacco small, and atmospheric pollution quite unlike that in England, though the history of Reykjavik is rather confused in this respect, as was pointed out above. In the course of years such comparative studies may enable one to assess the importance of these two factors."

For comparison Sir Ernest quotes figures for smoke estimations in the three countries.

COMPARATIVE MEASUREMENTS OF ATMOSPHERIC POLLUTION

	Smoke, mean mgm. in 100 m.^{3} air
Sheffield	
February 1948: 3 foggy days	173
" " 25 other days	40
" 1949	44
Salford (Manchester)	
November 1952 to January 1953	76
Leicester	
Whole year	21·5
Oslo	
1953, February, March November	5·5
" April to July	1·7
Reykjavik	
1953, August, September	1·0
" October, November	1·6

The report goes on to say: "In the smoke papers from Salford the following polynuclear hydrocarbons have been identified, and some of these have been estimated quantitatively: anthracene, pyrene, fluoranthene, perylene, 1 : 2-benzpyrene, 3 : 4-benzpyrene, 1 : 12-benzperylene, anthanthrene and possibly an alkyl pyrene and 1 : 2-benzanthracene. The relative proportions of these hydrocarbons, e.g., the ratio pyrene : 3 : 4-benzpyrene, differ in various products of combustion and such comparisons provide an interesting subject for study".

Research at the London Hospital has given some startling results. Croton oil, the best-known cocarcinogen (or promotor), can induce tumours when it is painted on mouse skin, provided the skin has been pretreated by a sub-threshold painting with a carcinogen. It has now been shown that urethane, which is a potent inducer of lung tumour, but is ineffective on skin, can act as an initiator for this tissue, for if croton oil is applied to urethane-treated skin, tumours do in fact arise. These findings have important possibilities, for there is no obvious reason why the urethane–croton oil combination should be unique.

---

* British Empire Cancer Campaign. Thirty-first Annual Report covering the Year 1953. Pp. xxxiv+468. (London: British Empire Cancer Campaign, 1954.)

At Leeds, Dmochowsky has found that the C_{57} black strain of mouse which is reputed to be non-susceptible to mammary cancer (incidence of the order of 1 per cent) has now developed a sub-line, the females of which are liable to this disease to the extent of 14 per cent; moreover, these mice now carry the viral milk factor.

The application of physics in the study of the cause and cure of cancer covers each year an ever-widening field, and while the same basic problems remain, they are being considered from an increasing number of directions. The varied use now being made of the fundamental principles involved in scintillation counting is a very good example of the application of new techniques to old problems. Dosimetry, which remains one of the perennial problems facing the medical physicist, is studied by means of probe-type scintillation dosimeters which are now in routine use for the measurement of the γ-radiation dosage-rate, and which are being modified at various centres for use with β-radiation sources and for the measurement of X-radiation. Various improvements in scintillation counters themselves are also reported, such as the increased sensitivity obtained in a collimated system with the use of a long, narrow crystal, the use of a double-probe unit coupled to a pen-recorder for measuring the rate of blood flow after the injection of sodium-24, and the technique of mixing the substance to be assayed with a liquid phosphor, such as one of the terphenyl-in-benzene type.

Radioactive isotopes have become an everyday aid in the study of a very large variety of problems, as well as a standard therapeutic procedure for many malignant conditions. The use of thulium-170 in radiographic work has been continued and a detailed study made of the physical characteristics of this isotope. The possibility of providing a method for the measurement of blood volume based on erythrocytes labelled with chromium-51 has been considered and work is proceeding on the estimation of the chromium-51 by means of its soft X-ray. Therapeutic procedures with radioactive isotopes still continue to receive careful attention as improvements and modifications of techniques are reported from various centres. The increasing use of cobalt-60 beam therapy units has led to studies of the quality of the radiation from the beam in water phantoms and also of the effects due to the presence of bone in the field being irradiated. Comparisons are made of the calculated and measured doses obtained in a model in which bones were embedded in tissue-equivalent wax when irradiated with rays from a cobalt-60 source and with X-rays of half-value layer 1·5 mm. copper and 50 cm. focal skin distance. The question of protection from these and other sources of high-energy radiation is one of particular urgency, and studies are reported of the measurements of both the quantity and quality of the radiation dosage liable to be received by workers in these departments. Education of technical and nursing staff is of importance in this respect, and efforts are being made to reduce the dosage-levels received, by nursing staff in particular, by means of lectures and demonstrations.

Reports on studies of plant interphase nuclei by means of interference microscopy, of the study of the electrophoresis of non-spherical particles, and of the ionophoresis of radioactive phosphate ions, are examples of some of the more unusual applications of physics to biological problems.

The pathological contributions to the report are, as usual, very mixed, whether considered from the point of view of subject, mode of presentation, or value; but they include—also as usual—a number of items of more than ephemeral interest.

The systematic accumulation of data at Great Ormond Street Hospital, London, on the tumours of childhood continues its ponderous but invaluable course. Dr. M. Bodian writes something more like a section of a text-book than a report, but at least the text-book is a good one and one that needs writing. This year's chapters deal with the teratomata, the lymphomata, and the adrenal, cervical and vaginal carcinomata. A discussion of the pathology of sacral teratomata from the point of view of their management in practice, and the identification of the relatively benign paragranuloma in three of seventeen children with Hodgkin's disease are of particular interest. Apart from this, there is a most interesting account from the same centre of the use of vitamin B_{12} in the treatment of neuroblastoma. This was originally used on the hypothesis that it might promote the maturation of neuroblasts to ganglion cells, a process which occasionally results in the spontaneous arrest of these tumours. No direct support for the truth of this hypothesis has been obtained, but in four of eight cases remissions have been seen, and three of the children are alive and free from symptoms after substantial periods—three years in one case. Because of the occasional occurrence of the spontaneous arrest already referred to, these results must be accepted with some caution; but if they fulfil their promise they offer hope of cure of a rare but deadly tumour. Suggesting as they do also a completely new line of tumour chemotherapy, their theoretical interest is perhaps even greater than their practical value.

The demonstration of a significantly high frequency of group *A* blood among patients with cancer of the stomach by workers at the Postgraduate Medical School, London, has been put on a firmer basis by the inclusion of statistics from several other centres, data on some thousands of cases being now available. It has been found that peptic ulcer presents an opposite effect: among patients with that diagnosis, group *A* is significantly less common, and group *O* more common than in the general population. It is cogently suggested that both these effects may be related to the high content of polysaccharides specific for blood groups in the gastric mucins. No other tumours of those investigated (Sheffield workers contribute a negative study of carcinoma of the breast on these lines) has shown any comparable effect.

The subject of the diagnosis of cervical carcinoma by cytological examination of the vaginal fluid has become the field of much partisan argument. It has become necessary to determine, not so much whether the method is of value, as whether the very large expenditure of skilled man-hours which it calls for is justified by the results in any given circumstances. Two correlated attempts at evaluation, sponsored by the Royal College of Obstetricians and Gynæcologists, are here reported from Birmingham and Newcastle. Though both are in their early stages, they have provided some useful data and provoked some valuable comments. The experiment in Birmingham of leaving not only the work but also the whole responsibility of cytological diagnosis in the hands of a specially trained technician will be watched with special interest.

There is a brief account of a visit paid by Prof. J. W. Orr to Makerere College in Uganda and of the tumour material he saw there. The observations he was able to make in the time at his disposal on Kaposi sarcoma and primary carcinoma of the liver were not spectacular; but the pattern of visitation is one which should be more widely followed, and which the British Empire Cancer Campaign is in a uniquely favourable position to foster.

SEVENTEENTH-CENTURY CHEMISTRY, THE PHLOGISTON THEORY AND DALTON'S ATOMIC THEORY*

By Prof. J. R. PARTINGTON, M.B.E.

SOME important aspects of seventeenth-century chemistry are exemplified by the work of Van Helmont (1579–1644), Boyle (1627–91) and Mayow (1641–79). Van Helmont, a physician, held views on education in advance of his time, thinking that young men in universities should learn mathematics and the sciences, including chemistry with practical work. He criticized the theory of the four elements and also the alchemical three elements, salt, sulphur and mercury, believing that air and water are the true elements; fire never forms part of a material body and earth can be formed from water, as he tried to prove by experiment. He made chemical experiments using the balance, and showed that a metal dissolved in an acid or converted into a compound is not destroyed but can be recovered again with the same weight and properties as before. The products of distillation do not exist as such in bodies, but are formed by the action of heat. Van Helmont coined the name 'gas' and recognized the existence of different gases, such as carbon dioxide ("gas sylvestre"), nitric oxide and sulphur dioxide. He thought that a gas cannot be retained in a vessel, since a sealed vessel containing materials generating gas is burst. Although a gas as such is not retainable by bodies, some bodies contain gas in a fixed form, and it can be separated from them by heat, fermentation or acids. Van Helmont represents the transition from alchemy to chemistry, and used the quantitative method.

Boyle was well acquainted with the writings of Van Helmont, whom he greatly respected. Like him, he retained some old ideas on superstitious remedies, comparing their action with that of a magnet on iron. In his "Sceptical Chymist" (1661) Boyle repeated and extended Van Helmont's criticism of the four elements and three principles, and confirmed many of his experiments. Both believed in the possibility of the transmutation of metals. Boyle was the first (1660) to collect gases (hydrogen and nitric oxide); he investigated the effect of pressure on air, discovering Boyle's law, and made many experiments in the vacuum of an air-pump. His experiments on combustion and respiration were made in dry vessels; he found little or no change of pressure or "elasticity" of air, taking this to be its most distinctive property.

Boyle attempted to rid chemistry of mysticism by using the ideas of rational mechanics in explaining chemical phenomena, and by the use of the atomic (or "corpuscular") hypothesis, which he took from Gassend, and of the ideas of Descartes, he interpreted physical and chemical changes in terms of the shapes and motions of the particles of bodies; acids have pointed particles, and air particles behave towards pressure like coiled springs.

In experiments on combustion Boyle found that gunpowder will burn under water or (with difficulty) in a vacuum, and hence he suspected that air contains some vital substance which may be a volatile nitre and which supports combustion and respiration. He thought nitre crystals might contain admixed air, although he admitted that, on heating, nitre may evolve vapours which "emulate air". Since combustion and respiration cause very little change of pressure of air in dry vessels, Boyle thought there was very little of this "fine subject" in the air.

In his experiments on the calcination of metals in air in sealed retorts (1673), Boyle was misled by his method of working, since he opened the retort before weighing (when air enters to take the place of that absorbed by the metal), and he concluded that the increase in weight is due to the fixation of ponderable fire particles in the metal. From his experiments on respiration (1672), he concluded that the burning of flames and the breathing of animals might remove the same substance from the air, but he gave other alternatives: they might remove different substances, since a flame is extinguished while an animal is still alive. His conclusions were (as usual with him) presented with great caution.

More definite conclusions were drawn from such experiments by Hooke and Mayow. Hooke ("Micrographia", 1665) suggested, without any new experiments, that air and nitre contain a common constituent, nitre more plentifully, and that a burning body dissolves in air, producing heat, as when metals dissolve in acids. It was not until 1682 that Hooke called the common constituent of air and nitre "nitrous air" (a name used by John French in 1651), and proposed a theory of combustion similar to that given by Mayow in 1674. Hooke, who otherwise claimed discoveries published by others which he thought belonged to him, did not feel that Mayow had taken anything from him, and the two were friends. It seems, in fact, that the theories of Hooke and Mayow were different, Hooke regarding combustion as a passive solution of a body in air, and Mayow as a violent collision and interaction of combustible particles and particles in the air which he called "igneo-aerial particles", "nitro-aerial particles" or "nitro-aerial spirit" (a name used by Scaliger in 1557). These particles, Mayow suggested, are contained in the nitric acid part of nitre, which derived them from the air.

Mayow was a highly ingenious experimenter, devising new apparatus for manipulating gases and in studying combustion and respiration, which he investigated in the presence of water and hence found a decrease in volume or pressure, not noticed by Boyle. He supposed that air contains two kinds of particles, one (the nitro-aerial particles) removed in combustion and respiration, and he explained the change of volume or pressure by an ingenious theory based on the views of Descartes and Boyle of the corpuscular structure of air. He explained the increase in weight of antimony on calcination as due to the fixation in the metal of nitro-aerial particles from the atmosphere. In respiration, he assumed, these particles enter the blood from air in the lungs, and animal heat is due to their interaction with combustible particles in the blood, this taking place in part in the muscles and being the cause of muscular motion. In these three processes, the nitro-aerial spirit plays the part of oxygen. Mayow's explanations were often artificial, since they were conceived in terms of the prevailing views of Descartes, which were also used by Boyle. Newton's "Principia" was not published until thirteen years after Mayow's "Tractatus quinque" (Oxford, 1674). Newton's chemical ideas in his "Optiks" (1717) are similar to Mayow's. Mayow's views on chemical affinity are very correct and anticipated those of Geoffroy (1718) and Berthollet (1801). The very severe criticism of Mayow by T. S. Patterson (1931) was exaggerated and incorrect in detail. Mayow's dependence on Descartes was overlooked, the originality of his experiments was not appreciated, and Mayow's supposed dependence on Boyle, Hooke, Lower and Thruston was based on ignorance of earlier work. The correct parts of Patterson's criticisms had been, unknown to him, anticipated by Jonathan Stokes in 1800. Indeed, a new study of Mayow, having due regard to the facts, is needed.

---

* Substance of a course of three lectures delivered in the University of London on May 5, 7 and 10.

The phlogiston theory is a complicated and difficult subject. The name "phlogiston" for a supposed material constituent of combustibles was used by Hapelius (1606), Van Helmont, Sennert and Boyle before Stahl, starting from some ideas of Becher (1669), proposed (first in 1697) what is called the old phlogiston theory. This was soon accepted and, combined with the replacement of Descartes's ideas by those of Newton, caused neglect of the more correct views of Boyle, Hooke and Mayow. The theory assumed that phlogiston is the material of fire, not fire itself; it is a dry earthy substance, soot being nearly pure phlogiston, although phlogiston was also supposed to escape in invisible particles from a burning body. It exists in animal, vegetable and mineral bodies, is the same in all, and can be transferred from one body to another. A metal is a compound of its ash (or "calx") and phlogiston; on heating in air the metal loses phlogiston, and on heating the calx with a body rich in phlogiston the metal is formed again. Sulphur is a compound of sulphuric acid and phlogiston; and all acids are modifications of sulphuric acid, the universal acid. Phlogiston is the cause of odour and colour.

Stahl's theory inverted the true theory of combustion and calcination and neglected quantitative aspects; although Stahl knew that the calx weighed more than the metal, he did not explain this, beyond saying that phlogiston is a weightless matter which when it enters bodies makes them lighter. The theory combined many isolated facts into a comprehensive body of false doctrine, made them easier to remember, and was very popular until towards the end of the eighteenth century.

As new facts accumulated the phlogiston theory underwent many modifications, including the views that phlogiston is hydrogen (Cavendish, 1766) or the matter of light (Macquer, 1749). The theory suggested new experiments: Scheele's discovery of oxygen 1772) was based on it, and Cavendish explained the synthesis of water (1784) in terms of it. Attempts to explain the increase in weight on calcination of a metal included the assumptions that phlogiston was lighter than air, or even that it had an absolute negative weight.

Lavoisier's theory of combustion was that oxygen gas is a compound of a base and the matter of heat or "caloric", an imponderable fluid which in some respects played the part of phlogiston. A burning body combines with the oxygen base and sets free the caloric as heat and light. This theory was seen to be unsatisfactory, since heat and light are evolved in the combination of solids as well as gases, and several modifications of it were proposed. In one, the combustible was assumed to be a compound of a base and phlogiston, and oxygen gas a compound of a base and caloric. The two bases combine to form an oxide, and the phlogiston and caloric combine to form light. It was only after the introduction of the theory of energy, about 1850, that a chemical explanation of the formation of heat and light in combustion was felt to be unnecessary, and the process was interpreted in a manner reminiscent of Mayow's theory—namely, as due to the collision of particles of the combustible and of oxygen.

Dalton's atomic theory was the first to make successful use of the old Greek theory of atoms in chemistry. The old theory had been used quite extensively in the seventeenth and eighteenth centuries by Gassend, Sennert, Magnenus, Boyle, Mayow and Newton. Newton's treatment of the physical nature of air, as consisting of particles repelling each other with a force inversely proportional to the distance (which gave Boyle's law), needed modification when air was recognized (as Mayow had seen) as containing two kinds of particles, and when different gases were discovered late in the eighteenth century and it was shown that two gases (ammonia and hydrochloric acid) combine to form a solid. Bryan Higgins (1776) supposed that gaseous particles are surrounded by mutually repelling atmospheres of caloric, and explained the formation of compounds $A+B$ of the atoms of two different gases. William Higgins, in his "A Comparative View of the Phlogistic and Antiphlogistic Theories" (1789), explained the formation of compounds of one atom of A with one, two, three, four or five atoms of B in terms of a force of attraction which divided itself among the combining particles. Although the law of multiple proportions may be read into his speculations, if Higgins supposed that the atoms of different elements have different weights, he expressed it so obscurely that authorities cannot agree on the matter.

John Dalton (1766–1844), born in Cumberland of a Quaker family and almost self-taught, became a schoolmaster in Kendal, where he wrote his "Meteorological Observations and Essays" (1793), containing the germs of his later discoveries. In 1793 he moved to New College, Manchester, as tutor, resigning in 1799, and thereafter supported himself by private tuition and consulting work. In his book, Dalton had proposed the new view that water vapour in the atmosphere is not chemically combined but mixed with the other gases. In developing this idea in 1801, he discovered his law of partial pressures, which he expressed in terms of Newton's theory by saying that particles of any one gas in a mixture repel one another but not the particles of other gases. He regarded the gaseous particles as surrounded by repelling atmospheres of caloric, and to explain gaseous diffusion he supposed that the atmospheres differed in size in different gases. From this view, in the autumn of

1803, he came upon the idea that atoms of different elements have different weights, and he probably presented the first table of atomic weights in a lecture in 1803 to the Manchester Literary and Philosophical Society, which was published in 1805. All the details of Dalton's chemical atomic theory are given, explicitly or implicitly, in an entry in his note-book on September 6, 1803 (his birthday), and he held these unchanged until the end of his life. Dalton calculated the atomic weights from the quantitative compositions of compounds and assumptions about the numbers of atoms of the elements in a particle of a compound. The numbers were not accurate, but they were based on analyses by well-known contemporary chemists, not by Dalton. He later said that he would publish only what he had confirmed, since he had often been misled, a statement which has erroneously been said to imply conceit on his part; there are, in fact, many assertions about Dalton based largely on ignorance.

The first printed statement of Dalton's atomic theory is that in the "System of Chemistry" (1807) of Thomas Thomson, who visited Dalton in 1804 and found him analysing marsh gas and ethylene, and Thomson afterwards said that Dalton's atomic theory was evolved to explain the results, which indicated a law of multiple proportions. The theory had, in fact, been arrived at in 1803. In 1808 Dalton gave a brief account of the theory in his "New System of Chemical Philosophy", with a table of atomic weights and plates of chemical symbols. He also gave some "general rules" for arriving at the numbers of the atoms of the elements A and B in a "compound atom" of a compound. If only one compound is known, it is $A+B$; if there are two compounds they are $A+B$ and $2A+B$ or $A+2B$, etc. Dalton had concluded from the combining volumes that equal volumes of gases cannot contain the same number of atoms (which is correct); but he did not consider the possibility that the particles of elementary gases may contain two or more atoms, and Avogadro's hypothesis (1811) was not used by chemists until Cannizzaro (1858) directed attention to it—it enables the numbers of atoms in a molecule of a compound to be found, and hence the atomic weights may be determined without ambiguity.

Dalton's atomic theory, it will be seen, differed in important respects from the modern theory, but it laid an enduring foundation for future progress. In addition to it, Dalton made important discoveries in chemistry and physics both before and after announcing his atomic theory. His work on the uniform expansion of gases by heat, on vapour pressures, on the law of partial pressures, and on gaseous diffusion was done in an early period (1800–04); later, important work was on the incomplete combustion of hydrocarbons (1805), on the volumes of solutions, and on the composition of the atmosphere at high altitudes, which he found nearly the same as at sea-level, explaining the result as due to convection (a theory proposed again in recent times). He was a skilful and accurate gas analyst.

Dalton became internationally famous after his publications in 1801. He was a *correspondant* member of the Paris Academy of Sciences in 1816 and one of the eight foreign associates in 1830, a Fellow of the Royal Society in 1826, a D.C.L. of Oxford in 1832 and in the same year an LL.D. of Edinburgh. In 1833 he began to receive a Civil List pension. He died suddenly in his room in 1844 and was buried in Manchester with civic honours. Dalton was greatly liked and respected by his contemporaries, his two main characteristics being his constant truthfulness and his great originality, both of which are quite incompatible with the assertion of Higgins in 1814 that Dalton arrived at his atomic theory by reading Higgins's book of 1789. There is no evidence that Dalton owed anything to his predecessors except Newton; this charge originated with Higgins alone, and if it has afterwards been repeated, it has always been withdrawn.

OBITUARIES

Prof. F. E. Fritsch, F.R.S.

F. E. Fritsch, emeritus professor of botany in the University of London, died on May 23 at the age of seventy-five. Of German descent, but born in London, he became truly English, though in his remarkable thoroughness and the solidity of his literary work he betrayed mental features held to be characteristic of German scholars. Asked how he managed to make fewer mistakes in his quotations and references than almost anybody else, he answered: "I am very slow though". This reply indicates how much time and trouble he devoted to every task he undertook.

Prof. Fritsch was head of the Department of Botany in Queen Mary College (University of London) during 1911–48. He began his academic career as assistant in the Botanical Department of the University of Munich during 1899–1901, then lectured in University, Birkbeck and East London (Queen Mary) Colleges of the University of London before taking the chair at Queen Mary College. He was president of Section K (Botany) of the British Association in 1927, president of the Linnean Society during 1949–52 and chairman of the Council of the Freshwater Biological Association of the British Empire.

Fritsch's inclination and gifts were more like those of a philologist commenting on ancient texts, and drawing careful conclusions from them, than those of a biologist who puts, by experimental means, his questions to Nature itself. But in his own investigations he was as painstaking and accurate as possible.

Since he came to be interested in morphology, the immense variation in the shaping of the Algae became, in his later years, his main attraction. There was scarcely ever a person who knew so much about them, and his life's work, "The Structure and Reproduction of the Algae", could not have been written by anybody else with the same degree of comprehension and authority.

Frail in body but strong in mind, Fritsch was a personality not to be overlooked in any assembly, and it is not surprising that he was often made a chairman by his colleagues. People used to look up to him, although he was small in stature.

Fritsch was asked for advice by numerous people who knew of his reputation as a most reliable man, and he did not spare himself, but he always kept his superiority. So long as this remained untouched, he could be the friendliest, most considerate and helpful man. He was a great talker, critical but benevolent, and resourceful in council.

Since his teaching, literary work and many dignities, combined with travelling—sleeping away from home and working in the train—eventually took most of his time and energy, gardening and music which had been his favourite spare-time occupations were gradually given up, but he did not rest much until near the end of his long life.

Fritsch's publications will remain standard works for some time to come. He himself will be missed by many as a strong supporter of order, prudence and loyalty. E. G. Pringsheim

---

The botanical world, and more especially the phycological section of it, has suffered grievous loss in the passing of Prof. Fritsch. Few men have attained the degree of eminence to which, despite physical frailty, his intellectual power, human wisdom and qualities of leadership raised him.

His primary interest was in the freshwater algae, in the study of which he made notable contributions to knowledge; but his interests were wide, and in the related field of marine phycology, his encyclopædic knowledge and sound judgment made him one to whom research workers in Great Britain and overseas turned inevitably for opinion and guidance. Help was always given freely and generously. He had that faculty of detached consideration of other people's problems that is not only invaluable but is also heart-warming and stimulating.

Prof. Fritsch's work, whether designed for the needs of elementary students or research workers, was always characterized by meticulous accuracy and a wealth of detailed information. The two volumes, "The Structure and Reproduction of the Algae", must remain as classic for all time; the completeness of the bibliography would alone ensure their permanent value, and that, coupled with the breadth and precision of the text, establishes the volumes as a *vade mecum* for all phycologists.

Though valuable scientific contributions, remarkable both in quantity and quality, earned for Prof. Fritsch both respect and admiration, his delightful human qualities also drew forth affection. It was a privilege to be associated with him for more than thirty-five years, and to have received from him an early training in university examining, in which his breadth of scholarship, fair-mindedness—especially to those less gifted than himself in graceful expression—provided an example to be remembered and followed.

Prof. Fritsch found great relaxation in music, and many of his friends will cherish memories of delightful week-ends at his home in Surrey where he and Mrs. Fritsch dispensed gracious hospitality. At the outbreak of the Second World War, Prof. Fritsch moved to Cambridge, where his home became again a social centre and focal point for botanists, from Great Britain and overseas. He faced the problems of war, as indeed he faced all other difficulties, with calmness, merely taking every possible precaution to safeguard scientific material and then going on quietly with his work, adding still further to scientific knowledge. It is regrettable that he himself will not see the publication of his current work on the calcareous algae.

Those who were privileged to be admitted to the friendship of Prof. Fritsch will be glad to express personal gratitude for unstinted and generous encouragement and to join with vast numbers of those who knew him in extending their sympathy to Mrs. Fritsch and her son. She must surely find some measure of comfort and pride in the knowledge of the sincere esteem and affection in which her husband was held by scientists all over the world.

Margery Knight
Lily Newton

Dr. Malcolm Burr

Dr. Malcolm Burr, whose death at the age of seventy-six, due to an accident, occurred on July 13 in Istanbul, was a most colourful figure. A mining engineer by training, he took part in the development of the Kent coalfield at the beginning of this century, prospected for coal in Angola and visited the Lena goldfields and manganese mines in the Caucasus between the two World Wars, not to mention many other professional tasks. His main scientific interest in life, however, was entomology, and even as a schoolboy he specialized in Orthoptera and Dermaptera. When only twenty years old, he visited Vienna and, under the stimulus of Dr. Brunner von Wattenwyl, produced a revision of the genus *Acrida*. A long series of articles on the systematics of other Orthoptera followed, as well as a monograph of the family Eumasticidae, the first of this group. His principal contribution was to the study of the Dermaptera, which he was the first to classify on the basis of the structure of the copulatory organs, and on which he published a classical revision in Wytsman's "Genera Insectorum", as well as a volume in the "Fauna of British India", apart from very numerous journal papers. Dr. Burr's valuable collection of world Dermaptera, containing many type-specimens, has been presented by him to the British Museum and his rich collection of European Orthoptera, including many collected by himself, to the Hope Museum, University of Oxford.

Financial misfortunes and a restless character made it impossible for Burr to settle down, and in his old age he became a journalist, author of delightful travel and natural history books and finally professor of English at Istanbul. One of his most remarkable abilities was the gift of learning languages—he spoke fluently all the European ones, including several Slavonic. His last letter to me, dated July 2, 1954, full of entomological inquiries, was written in a vivid, if not strictly grammatical, Russian, a language which he never attempted to learn, but merely 'picked up' during his visits to Russia more than thirty years ago and never forgot.

The Royal Entomological Society of London has lost in Dr. Burr one of its oldest Fellows, elected in 1896. Apart from his many publications, he rendered an important service to entomology by having been one of the active group which founded the International Entomological Congresses and the honorary secretary of their permanent executive committee until 1920. B. P. Uvarov

Dr. R. W. Pocock

Dr. Roy Woodhouse Pocock, formerly a district geologist of the Geological Survey of Great Britain and a member of its staff for thirty-six years, died suddenly on June 22, while on holiday in Brussels.

Pocock was born in 1887 and, after leaving school, he became an assistant in the Geological Department of the British Museum (Natural History), in the meanwhile working for an honours B.Sc. degree at evening classes at Birkbeck College, London. During this time he began an investigation of the Silurian inlier of Woolhope, Herefordshire, and discovered there a thin limestone largely composed of the remains of the crinoid *Petalocrinus*, previously known only from the Niagara Limestone of North America and the Silurian beds of Gotland. He presented specimens from Woolhope to the British Museum

(Natural History) in 1911; but his work on the "*Petalocrinus* Limestone" was not published until 1930, in the *Quarterly Journal of the Geological Society of London*.

Pocock was appointed to the Geological Survey in 1912 and for about two years was assigned to work in Hertfordshire. During the First World War he was one of three members of the Geological Survey staff selected to go to the Eastern Mediterranean to advise on problems of water supply for the Army. On his return to England he received a commission in the Royal Garrison Artillery.

After the First World War, until his promotion to be district geologist in 1937, Pocock took part in the surveying of six one-inch sheets covering areas in Shropshire, Staffordshire and Worcestershire, and was principal or part author of the corresponding memoirs. His work in the western part of the Coalbrookdale Coalfield led to his contributing to the "Summary of Progress of the Geological Survey" for 1925 a paper on "The Basalt of Little Wenlock", in which he demonstrated the rock to be a lava of Lower Carboniferous age. Pocock extended his investigations to basalts among Upper Carboniferous sediments in the Midlands and, in a paper published in the *Quarterly Journal of the Geological Society* in 1931, concluded that all of them are of Carboniferous age and most of them of extrusive origin. The latter contention has not in all cases met with general acceptance. For his work on "The Age of the Midland Basalts", his *Petalocrinus* paper and other writings on the geology of the Welsh Borderland, Pocock was in 1932 granted the D.Sc. degree of the University of London (not an 'honorary' degree as has been stated elsewhere). His official work in Shropshire resulted also in his collaborating with E. S. Cobbold in a paper on "The Cambrian Area of Rushton, Shropshire", published in the *Philosophical Transactions of the Royal Society* in 1934.

On his promotion to be district geologist, Pocock took charge of the Bristol and South Wales District, and himself carried out mapping of rocks of Silurian and Old Red Sandstone age in the Chepstow Sheet. He retired from the Geological Survey in 1948.

Pocock was awarded the Lyell Fund of the Geological Society in 1932. He served on that Society's Council during 1937–42 and was a vice-president in 1941 and 1942. He was treasurer of the Geologists' Association during 1950–52.

T. H. WHITEHEAD

NEWS and VIEWS

Mathematics at the Imperial College of Science and Technology: Prof. H. Levy

PROF. H. LEVY joined the staff of the Mathematics Department of the Imperial College of Science and Technology, London, in 1920 from the Aerodynamics Division of the National Physical Laboratory. He was appointed professor in 1923, succeeded Prof. S. Chapman as head of the Department in 1946, and was also dean of the Royal College of Science from 1946 until 1952; he is due to retire this year after thirty-four years continuous service in South Kensington. In that time he has achieved much distinction; academically he has been the inspiration of a gradual and forceful revolution in the content and quality of the mathematics instruction and research at the College. He has never allowed himself to rest contented with his achievements, and continues still to work to keep the Department abreast of the rapidly changing demands of present-day science and technology. In the College he has been well known to generations of students in all departments. With an unfailing sense of humour, and a human sympathy, he is one of the most approachable of men and is never too busy to talk with anyone who desires his help. He has preserved an independence of outlook and possesses a remarkable facility of spontaneous and sensible expression which, when he leaves, will be missed by his colleagues on many boards and committees. For the time being, however, they are fortunate in that Prof. Levy has agreed to delay his retirement for six months.

Geography at Edinburgh: Dr. J. W. Watson

DR. JAMES WREFORD WATSON, chief geographer of Canada, has been appointed to the chair of geography in the University of Edinburgh in succession to the late Prof. A. G. Ogilvie. Born of missionary parents in China in 1915, Dr. Watson spent his early years in the Far East, but went to Edinburgh at the age of twelve to be educated at George Watson's College and the University, where he graduated with first-class honours in geography in 1936. After two years as lecturer at the University of Sheffield, he was invited to introduce the teaching of geography to McMaster University, Ontario, first as lecturer and later as professor (1945–51). During this period he took his Ph.D. at Toronto and was for a time visiting professor at the University of Florida. In 1949—being 'lent' for a time from McMaster—he was appointed the first chief geographer of Canada and director of the Geographical Branch of the Federal Government. In this capacity he has initiated and organized a great variety of geographical surveys, many of them in the Canadian Arctic. He has also been responsible for compiling and editing the new "National Atlas of Canada", to be published in 1955. Besides extensive travel in North America, he has a first-hand knowledge of many parts of South America, Greenland and several European countries. Although so much of his working life has been spent in administration and travel, and in the supervision of the researches of others, Dr. Watson has found time for a good deal of personal research, recorded in twenty-five papers, some of which are substantial studies in sociological, economic and historical geography, marked throughout by originality of approach and method and by clarity of expression and illustration. Early this year he received an Award of Merit from the Association of American Geographers for his "distinguished services in the establishment of a geographical office in the Canadian Government and for original contributions to the historical geography of settlement".

Chemicals in Food

AT the eighth annual general meeting of the British Food Manufacturing Industries Research Association, held on June 3, Sir Frank Engledow, in his presidential address, surveyed the problem of chemicals in food against the background of the fourth annual report of the Advisory Council on Scientific Policy, 1950–51 (Cmd. 8299; H.M.S.O.). This report states "that the risk to life and health due to the presence of toxic substances in consumer goods is probably small, but the rapid growth of chemical industry, and the needs of the food-processing industries for substances to replace scarce materials or for chemical substances which have a claim to use on their own merits as improvers of appearance, palatability or texture of manufactured foods, are accelerating the pace at which new chemical substances are being introduced into consumer products, and the machinery which exists for testing the possible harmful effects of these substances is inadequate". Sir Frank suggested that the food industries should searchingly examine their own attitude with the view of the formulation of a policy "constructively, not merely defensively". It is completely indefensible, he said, to attempt to offset the seriousness of the problem by comparisons with other hazards to health, such as those arising from atmospheric pollution and other causes; but the time is opportune for the preparation by industry of a reasoned case demonstrating the necessity of various methods of food preservation for different purposes, to make full use of seasonal crops, to allow for necessary delays in manufacturing processes and to ensure the distribution of world or national food supplies over wide areas. Such a statement might constitute a valuable contribution to public understanding and would help the industries to make sure that they are fully meeting their responsibilities by thoroughly probing all the complex issues. It is essential, Sir Frank continued, that all food firms should make full use of the whole of existing knowledge and take a scientific attitude to it; the British Food Manufacturing Industries Research Association can play a very important part and warrants the support of all firms in the industries concerned.

Legal Protection of Laboratory Animals Overseas

Some time ago, two scientists working in another country asked the Universities Federation for Animal Welfare (Great Britain) to suggest a form of legislation for the protection of laboratory animals which they might urge their own Government to adopt. In order to clarify the legal requirements, the Federation has drafted a summary of the Cruelty to Animals Act, 1876, and of the practices which have gradually come to be based upon it.

In Britain, the preparation of biological therapeutic substances for medical and veterinary use is controlled by statutes other than the 1876 Act; the animals involved are subject to inspection, and the Universities Federation for Animal Welfare considers this legal control and inspection important. The relevant British statutes are the Therapeutic Substances Act, 1925, and subsequent rules and orders, administered by the Ministry of Health, and the Diseases of Animals Act, 1950, and Diseases of Animals (Therapeutic Substances) Order, 1952, administered by the Ministry of Agriculture. The protection of all other laboratory animals is in the hands of the Home Office, which is equivalent to the Ministry of the Interior in most countries. The Federation considers that this is a good arrangement, since the Home Office is in a position to give an unbiased opinion when the claims of science have to be weighed against the welfare of laboratory animals. The Federation also considers that special breeding of all laboratory animals is desirable. In Britain many institutions breed their own animals, and a list of accredited breeders has been compiled by the Laboratory Animals Bureau, Medical Research Council, Holly Hill, Hampstead, London, N.W.3.

Ten-Tola Primary Standard Weight for Karachi Mint, Pakistan

L. Oertling, Ltd., have completed the manufacture for the Karachi Mint, Pakistan, of what is believed to be the first primary standard weight manufactured commercially in Britain since before the War. The weight is of iridium–platinum alloy and is a cylinder having a diameter equal to its height with a mass of 10 tolas (1,800 grains or about 117 gm.). The billet from which the weight was manufactured was forged by Johnson Matthey and Co., Ltd., Hatton Garden, London, E.C.1, and the production of such a billet to very close specific gravity limits reflects great credit upon their skill. The certification of the specific gravity and the accuracy of adjustment was carried out by the National Physical Laboratory, Teddington. A special pair of forceps, container and carrying case are provided. The manufacture and adjustment of a weight in the form of a solid cylinder to an accuracy of two parts in one million represents a skill of a very high order. Since it is impossible to make any adjustment to the weight should it become too light, the weighing and counter-weighing of the mass becomes extremely critical as the limits of adjustment are approached; this work was carried out in the Weight Department of Messrs. Oertling.

The British Civil Service, 1854–1954

At the suggestion of the Civil Service National Whitley Council, Mr. Wyn Griffith has written an excellent concise account of "The British Civil Service, 1854–1954" (pp. 32+4 plates. London: H.M.S.O., 1954; 1s. net) which has been published "at the direction of H.M. Treasury" on the occasion of the centenary of the publication of the Northcote–Trevelyan Report. In the broad perspective of this commemorative booklet, though the change in character and responsibilities of the Service are noted, the treatment of these aspects of special interest to the professional man, and particularly the scientific worker or technologist, is slight; nevertheless, the growth of the Scientific Civil Service is described as the outstanding development of recent years. Read with intelligence and reflexion, the booklet gives a clear enough guide to the real problems of the Civil Service to-day and the factors which determine its strength and weakness (see also p. 281 of this issue).

New Technical Bulletins on Rubber Research

The first of a series of technical bulletins to give information on new materials and processes resulting from the research and development work of the British Rubber Producers Research Association has just been issued by the British Rubber Development Board (Market Buildings, Mark Lane, London, E.C.3). The object of the bulletins is to provide factual information, particularly for the industrial technologist, on subjects which have reached a stage of more practical interest. They will therefore supplement to some extent publication of the Association's work in technical and scientific journals. "B.R.P.R.A. Technical Bulletin No. 1: Heveaplus M" is a well-produced, illustrated booklet (pp. 20; 1954) which describes various products obtained by treatment of hevea rubber latex with methyl methacrylate. These products are of much interest since they represent successful attempts to improve natural rubber and to confer on it some of the various advantages which have been claimed for speciality synthetic rubbers. 'Heveaplus MG' is a graft polymer obtained by polymerizing methyl methacrylate in rubber latex, while 'Heveaplus MM' is prepared by mixing a dispersion of polymethyl methacrylate with concentrated ammonia-preserved rubber latex followed by coagulating, washing and drying. In both types, a final number indicates the percentage of (poly) methyl methacrylate present in the product. Details of the chemical and physical properties, processing, vulcanization, reinforcing power, etc., of these interesting new materials are also given.

Properties of Materials at Low Temperatures

ANNEXE 1954–2 of the Bulletin of the International Institute of Refrigeration (177 Boulevard Malesherbes, Paris 17^e) records the proceedings of the meetings of Commissions 1 and 2 of the Institute held at Zurich in September 1953; the publication has just become available. Nineteen papers were presented and some of the topics discussed are indicated below. A paper by Long and Simon describes a helium liquefier constructed with an elastic metallic bellows in place of the conventional cylinder and piston. Van Itterbeek describes an adaptation of the Collins liquid helium cryostat to a closed cycle so that the same quantity of helium gas is circulating and the loss reduced to a minimum. An apparatus which permits of the liquefaction of hydrogen and helium in the same unit is described by Spoendlin, and Myncke describes a liquid-air plant with propane precooling circuit. Wucherer reviews the development of expansion turbines for low temperatures and quotes figures for the high efficiency attainable. Heat-transfer calculations for a cross-flow regenerator are given by Hausen. Four papers deal with the low-temperature properties of metals: the mechanical properties of ferritic steels at −196° C., by Allen; the effects of low temperatures on some engineering properties of metals, by Oliver; the thermal conductivities of metals below room temperatures, by Powell; and strength of aluminium crystals at low temperatures, by Eder. Two papers deal with thermal insulation problems: one on the thermal conductivity of porous materials containing air under reduced pressure, by Paemel; and a note on the thermal conductivity of moist cork, by Hatton and Zaki. A survey of the field of work of Commission 2, which has for its terms of reference the study of heat transfer, insulating materials, instrumentation, and thermal properties of materials, was given by Griffiths. The next joint meetings of Commissions 1 and 2 will take place at Grenoble on September 24 and 25 of this year.

Constants of the Stellar Velocity Ellipsoid

WHEREAS previous derivations of the constants of the velocity ellipsoid of stars have been based on the radial velocities of the brighter stars, in a paper by D. G. Ewart (*Mon. Not. Roy. Astro. Soc.*, 113, 5; 1953) the derivation is based on the radial velocities of 820 stars the *HD* photographic magnitudes of which range from 8·5 to 8·6 and the spectral types of which are *F–M*. The calculations were simplified by using large regions of the sky, which was divided into thirty-four areas, according to galactic latitude, and antipodal areas were combined to give seventeen regions over one hemisphere. The final results for the solar motion were: $U = 20 \cdot 36$ km./sec.; $A = 275° \ 07'$; $D = + 40° \ 44'$; $G = 35° \ 53'$; $g = + 21° \ 18'$, with a K term of $- 0 \cdot 22$ km./sec. The mean results previously obtained by Moore and Paddock were: $U = 22 \cdot 44$ km./sec.; $A = 280°$; $D = + 44° \ 30'$, from which it appears that the high value of the declination of the solar apex obtained by Moore and Paddock is partly confirmed by Ewart's work. It is suggested, however, that as the stars used in earlier work on radial velocities were generally brighter than the sixth apparent magnitude—very much brighter than those used in the present investigation—there may be a magnitude variation in the solar motion.

The same division of the sky was used for the determination of the constants of the velocity ellipsoid, and a table shows the values obtained for $1/K$, $1/H$, K/H and G_s for the different zones; but it is pointed out that the only result to which any significance can be attached is that for all stars. In this case the values are 37·24, 25·80, 0·693 and 321° 44′ ± 3° 31′, respectively, one main feature of which is that the ratio $K/H = 0 \cdot 693$ is well defined and agrees closely with proper-motion results. Delhaye's figures, published in 1952, obtained by analysing the proper motions of faint stars in the Boss General Catalogue, indicated that the phenomenon of the deviation of the vertex is confined to the nearest stars and is not exhibited by the fainter and more distant stars, and it is significant that in Ewart's investigation the deviation of the vertex is barely evident. It is suggested that there should be further examination for a possible variation of the declination of the solar apex with apparent magnitude, and also for the dependence of the deviation of the vertex on the distances of the stars used in its determination.

Radioactive Tobacco Mosaic Virus

F. L. WYND has reported on the preparation of radioactive tobacco mosaic virus (*Lloydia*, 16, No. 4, 233; 1953) by growing young tobacco plants in hydroponic culture low in phosphate for three weeks. Radioactive phosphorus in the form of orthophosphoric acid was then added to the nutrient solutions and seven days later each plant was inoculated with the disease by rubbing the lower leaf with liquid obtained from macerated diseased leaves. Sixty-two days after inoculation, the plants were harvested and the virus recovered by differential ultracentrifugation. A purified virus suspension was obtained exhibiting a radioactivity of 2·54 μc./mgm. of virus phosphorus. This activity was significantly greater than those reported by previous investigators. The probable purity of the recovered virus was evidenced by electron photographs. The high radioactivity of the purified virus should permit its use in further studies of certain aspects of the physiology and biochemistry of this virus disease.

The Council for the Preservation of Rural England

THE twenty-eighth annual report of the Council for the Preservation of Rural England quotes an example from Sheffield to illustrate the need for constant vigilance in seeing that land scheduled as 'green belt' in local authorities' development plans is not used for other purposes. The Sheffield and Peak District Branch of the Council is very concerned about possible encroachments on the Sheffield 'green belt' as envisaged in the City's Development Plan. At a public inquiry in July 1953 the Branch lodged certain objections and received an assurance that various farm lands left uncoloured on the map and designated as agricultural areas would not be interfered with and would continue, as shown in the development plan, in their existing use. Before the decision of the Minister of Town and Country Planning could be promulgated, and within less than seven months from the inquiry, the Branch reports that Sheffield City Council has adopted a resolution to change certain provisions in it and to allocate portions of this land for building, without formal amendment or a public hearing. It would appear, therefore, that 'unallocated' land in a development plan can be developed at any time. If this is not the case an official assurance to the contrary would be welcomed.

Numbers of Man and Animals

THE Institute of Biology is organizing a symposium under the general title "The Numbers of Man and Animals", to be held at the Royal Geographical Society, London, during September 24–25. The symposium is to be opened by Sir Alexander Carr-Saunders, and the first session will be concerned with the varied approaches of the economist, demographer and anthropologist, papers being given by A. T. Peacock, E. Grebenik and Prof. I. Schapera. The second session (chairman, Prof. C. H. Waddington) will begin with a study of the mathematical approach to population dynamics by Mr. J. G. Skellam. Dr. D. S. Lack, D. H. Chitty and Prof. T. Park (Chicago) will then deal with various aspects of the study of animal populations. The third session (chairman, Prof. J. Z. Young) will be concerned with the effects of disease, fertility and nutrition on the structure of populations. Papers are to be given by Dr. A. S. Parkes, Prof. A. L. Banks and Dr. J. Hammond. In the final session (chairman, Prof. S. Zuckerman) Dr. Fraser-Darling is to speak from the point of view of the ecologist, Prof. L. S. Penrose will discuss changes in the quality of human populations and Lord Boyd-Orr will comment on the future outlook. Copies of the various papers will be available some weeks before the meeting. Further information can be obtained from the General Secretary, Institute of Biology, Tavistock House South, Tavistock Square, London, W.C.1.

Ninth Electronics Course at Harwell

APPLICATIONS are invited by the Atomic Energy Research Establishment, Harwell, from physicists and electronic engineers holding a degree or equivalent qualification, who wish to attend the ninth electronics course. The course covers the design, use and maintenance of electronic instruments used in nuclear physics, radiochemistry, and in work with radio-isotopes. It is to be held at the Isotope School, Harwell, during November 1–5. Attendance at the course is limited to 12 students. The syllabus will include lectures and practical work concerned with counters, D.C. and pulse amplifiers, coincidence units, scalers and ratemeters, and the lecturers and demonstrators will be specialists from the Atomic Energy Research Establishment. The fee for the course is twelve guineas, and living accommodation can be arranged locally at a charge of five guineas approximately. Further information can be obtained from the Electronics Division, A.E.R.E., Harwell, Didcot, Berks. Application forms must be returned by October 15.

Announcements

THE Royal Society of Arts has awarded the R. B. Bennett Empire Prize of 100 guineas for 1954 to Dr. C. J. Mackenzie, president of the Atomic Energy Control Board, Canada. The Prize was founded in 1945 by the late Viscount Bennett, a former president and chairman of council of the Royal Society of Arts, and is awarded every three years "for the most outstanding contribution from the Dominions, India, Burma and the Colonies, to the promotion of the arts, agriculture, industries and commerce of the overseas empire during each intervening period".

DR. A. FRÖHLICH, lecturer in the University College of North Staffordshire, has been appointed to the University readership in pure mathematics tenable at King's College, University of London.

THE annual conference of the Society of Leather Trades' Chemists will be held in the Large Chemistry Lecture Theatre, University of Leeds, during September 24–25. On the afternoon of the first day, the sixth Procter Memorial Lecture of the Society will be delivered by Prof. J. T. Randall, Wheatstone professor of physics, King's College, University of London, his subject being "Observations on the Collagen System". Further information can be obtained from the honorary secretary, G. H. W. Humphreys, Forestal Central Laboratories, Harpenden, Herts.

FROM August 18 until the end of the year, the Science Museum will be showing some of the most important books on astronomy which were published between the fifteenth and the middle of the nineteenth centuries. The exhibition will include copies of Newton's "Principia", Copernicus's "De Revolutionibus Orbis", as well as works of Tycho Brahe, Kepler, Halley and Herschel. The exhibition will include photographs of many of the illustrations in the books. The Royal Astronomical Society has lent a number of books from its library to supplement the Science Museum's own collection.

A COURSE on the measurement of the particle-size characteristics of fine powders will be given by Dr. H. E. Rose in the Faculty of Engineering, King's College, University of London, during the week commencing September 27. The course is primarily intended for graduates engaged in industry and will consist of a series of lectures, tutorials and demonstrations in the more common techniques for the determination of the size-characteristics of powdered materials in the sub-sieve range. The fee is five guineas. Forms of application should be returned not later than September 10, and further information can be obtained from the Dean of the Faculty of Engineering, King's College, London, W.C.2.

THE X-ray Analysis Group of the Institute of Physics will be holding its autumn conference during October 22–23 at the Royal Institution, Albemarle Street, London, W.1. The subjects to be dealt with at the conference will be the structure and texture of metals. There will be an evening discourse on October 22 by Prof. A. H. Cottrell on dislocations. The conference is open to all, without charge, on completion of an application form, copies of which can be obtained from the Deputy Secretary, Institute of Physics, 47 Belgrave Square, London, S.W.1.

WE regret that Sir Harold Hartley's signature was inadvertently omitted from the obituary notice of Dr. O. J. R. Howarth published in *Nature* of August 7, p. 249, although it appeared in the list of "Contents".

SCIENCE IN THE MODERN WORLD

In a paper entitled "The Task before Us", read before the American Academy of Arts and Sciences at Boston on April 14[*], Dr. P. W. Bridgman examined the philosophy of the founding fathers of American democracy in the light of the scientific thought of this century. He suggested that we have forgotten to regard democracy as a growing thing, evolving to meet our changing conceptions of ourselves and our place in Nature. Anti-intellectualism, he said, might be a symptom of something more deep-seated, and the emphasis on a return to humanistic attitudes requires a revitalization of the humanities themselves in the light of our recent intellectual experiences. We need to assimilate into our whole intellectual outlook, and in particular into our relation to social problems, the lessons implicit in scientific experience. Considering first the changes in intellectual attitude forced on us by such experience, Dr. Bridgman said that a necessary mark of a liberally educated man is the realization that our thinking and intellectual processes in general cannot be taken for granted. When we think, we use intellectual tools, and these tools have properties and limitations. In particular, recent experience shows that when we push the application of many of our concepts into new fields, limitations appear which we could not have anticipated from anything in our former more limited common-sense experience. We have now come to expect that a concept inherited from our ancestors will not be applicable when pushed into fields hitherto unentered. Analogy suggests that the presumption is that such concepts as human rights or duties or responsibilities require modification when the environment in which they arose is altered, as it now is, by technological advances that bring all men over the whole world into immediate mutal relations.

Dr. Bridgman suggested that it is not a common idea that there are still regions in which the man of science is groping his way and knows that he has not yet found the answers. Failure to realize this is one reason for the impatience of people with the scientific point of view and for the urge to return to a more humanistic outlook. Among such unsolved problems, Dr. Bridgman gave as examples that of the 'observer' in quantum physics and the growing concern with the basic problem of what sort of thing a brain is. One of the results which is beginning to emerge from cybernetics is a realization of the extent to which our conscious activities have to be selected from the overwhelming number of potentialities. The problem becomes not to find the absolute truth but to find how to do the best we can with what we have. Moreover, in psychology the new approach to the nature of perception is forcing on us the simple realization that all our conscious thinking is done in terms of perceptions, and we are now asking whether in the domain of ordinary experience the mould of space and time into which perception pours our world is a good mould. Dr. Bridgman believes that our task is to find the present status, in the light of all the insights now available to us, of such fundamental concepts as human rights, freedom, equality, duty and justice, and in the light of these insights to strengthen if possible, or to revise if necessary, the conceptual foundation of our social and political system. This task will demand a long campaign of education and the slow development of new intellectual techniques by a process involving much trial and error.

Reviewing more concrete aspects of the situation, Dr. Bridgman believes that analysis of the processes in a democratic society will in this way lead us to a society in which the relation between society and the individual is based on mutual advantage and service. Only exceptionally will it involve honouring minimum claims on the community whether or not any return is made; but it will also involve a revision in the philosophy underlying the system of taxation. Finally, it will place emphasis on two virtues: the repugnance of the individual to exercise force against his neighbour for his own advantage, and the imagination that can sense the significance of the simple underlying processes and relations so easily lost to sight under the complexities of modern life—or, in other words, intelligence.

THE OIL INDUSTRY

The oil industry is one which could be said to be less than a hundred years old, or more than two thousand.

It seems probable that it was an ingenious Chinaman who first drilled a hole into the earth's surface. He was in search of salt water and natural gas which he could use as the fuel to evaporate the water to yield salt. In the process he or his successors at times bored down to three thousand feet and incidentally struck oil. They had no use for the oil except as a lubricant (*Esso Magazine*, 3, No. 11; Spring, 1954).

The rig these Chinese devised is basically not unlike the cable rig used to-day; it sometimes took them ten years to drill a deep hole with their rigs.

Drake used the cable rig method when drilling the world's first commercial oil well in 1859. It was fortunate that he made his attempt in Pennsylvania rather than in Texas, because when the drillers got to Texas they encountered softer rock formations in which the simple cable rig was useless; the sides of the holes caved in as fast as the bits pounded through. As a result the rotary rig came into being; with this a hole is drilled through rock instead of being pounded through. A length of piping with a 'bit' on its end is gripped and rotated like a carpenter's drill. Mud, forced down the pipe, comes to the surface again in the space between pipe and hole, thus sealing off loose formations as the hole is drilled and bringing the cuttings to the surface. Two-thirds of wells sunk to-day are drilled by rotary rigs.

The drill pipe has greater precision than the cable for deeper holes; it also goes down straighter. This is important to-day, when wells are being drilled deeper every year.

During the Second World War there was not enough easily located shallow oil to keep industry and machines operating. New sources had to be found. The drillers' bits now probed the rock formations of the Eocene and Oligocene ages; soon wells were being drilled to 12,000 ft. To-day, in the United States alone, ninety-seven wells are being operated at depths below 15,000 ft., of which twenty-two were drilled last year.

Difficulties increase, and costs multiply, with greater depths. (A 15,000-ft. well is three times as expensive as one of 10,000 ft. It may cost anything up to £400,000 to drill.) The strains imposed on rigs at a depth of two or three miles are vastly greater than with more shallow wells. Derricks have to be of much heavier construction to take the weight of the drill pipe and to hoist it up out of the hole. The heat at 15,000 ft. seriously interferes with the effectiveness of the normal drilling muds. Bits wear out more quickly owing to the greater density and hardness of the deep rock formations. Pipe that is fully adequate to drill to 5,000 ft. will twist at double that depth and drill crooked holes. The recent use of diamond bits for deep-hole drilling has eased the problem.

The world's deepest well had reached 21,482 ft. a little time ago when it was halted by a core stuck at the bottom and the drill pipe stuck at 12,000 ft. The core will reveal whether the well has reached formations of the Oligocene age. If it is still in shales of the lower Myocene age, drilling may be discontinued—with no oil found.

One of the most interesting of recent developments has been the adoption of directional drilling, the process whereby the direction taken by the bit can be changed while drilling is in progress—or the well can be drilled from the start at a chosen angle from the vertical. By this technique it is possible to deflect a hole from an unproductive to a productive part of an area and so save the time and cost of drilling again from the top; the hole can be deflected around particularly hard and difficult underground formations; a fire at a well can be brought under control by drilling a slanted relief well into it; by the same means one can drill under the sea from dry land.

The angle of drift is effected by means of a tool called a whipstock; this is a 'cone' which is lowered into the hole base first with its apex pointing upwards. A drilling bit will always follow the line of least resistance and, when it encounters the apex of the cone, it is naturally deflected from its vertical path at an angle, the angle being dictated by the shape of the whipstock used. Normally, the full angle to which it is intended to deflect a hole is made by a series of whipstock operations, the drift being increased 2–3° every hundred feet until an average angle of 10–45° has been obtained. Directional drilling programmes have been known to achieve a drift of 80° to a vertical depth of 8,000 ft.

Drilling practice is never static. The direction of advance has been and will be towards the automatic rig. The most difficult task has always been the racking of the drill pipe as it comes out of the hole in sections of ninety feet or more. Steel arms at various heights have now been evolved to do this automatically. Unscrewing the pipe joints also taxes the strength of the operators. Chains on winches have been used for twisting the pipe, but power-driven 'tongs' have done this by the push of a lever. To speed drilling a jet bit has been produced.

The greatest depth at which oil has been discovered is 17,895 ft. It is hoped that much more will be discovered below 20,000 ft.

SELECTION OF SUPERVISORS

In June 1948, the National Institute of Industrial Psychology's Foremanship Research Group conducted an experimental selection procedure in a large heavy-engineering works in Scotland. Two different selections for promotion to supervisory positions were made from a field of 110 candidates, obtained by advertisement within the firm. The first selection was made by management by their customary method of review and nomination; in the second, from the same field, systematic methods were used, including biographical history sheets, recommendation forms, intelligence tests, interviews, group discussion sessions, and a final selection panel. The latter procedure was carried out by members of the management with the advice and assistance of a member of the staff of the National Institute of Industrial Psychology.

After two years a check was made and gradings by the selection panel for the 44 men regarded as worth serious consideration for promotion correlated $0 \cdot 68 \pm 0 \cdot 08$ with assessments made on these men by their managers two years after the original selection. This was an encouraging result in comparison with the poor prediction, $0 \cdot 23 \pm 0 \cdot 14$, obtained by management's normal procedure. Another check has now been made by J. D. Handyside and D. C. Duncan some four years and five months after the original selection experiment*.

Two criteria were available against which to assess the efficiency of selection: first, ratings by managers who were in a position to assess the performance of the men concerned; and, secondly, whether the men had been promoted twice, once, or not at all during the four and a half year period.

Management's customary method of selection consisted of short interviews by the candidates' managers and discussion among managers who could be expected to know the men reasonably well. The results of the experimental evaluation of this method indicated that it was defective to a startling degree.

It appears from this experiment that a combination of existing, fairly elementary, selection techniques permits prediction of supervisory success—as measured by management criteria—just about as well as the uncertainties of the criteria allow. Nevertheless, there is a need to improve the economic efficiency of the selection methods.

GULMARG RESEARCH OBSERVATORY

By Prof. P. S. Gill

Director of the Observatory and Head of the Department of Physics, Aligarh Muslim University

With the development of the subject of cosmic radiation the need for stations at various heights and in different parts of the world has become increasingly important. Previously, the high-altitude research stations were used for astronomical, astrophysical, meteorological and terrestrial magnetic measurements; but during recent years these stations have become mainly associated with the work in cosmic rays. In the Americas, a number of high-altitude research stations have been established through the efforts of cosmic-ray investigators, some of which—Mount Evans, Echo Lake, Climax, Mexico

City and Huancayo—are well known; in Europe, too, there are a number of stations, the best-known being the Jungfraujoch in the Alps.

Within the past fifteen years, cosmic-ray studies in India have been initiated in a number of institutions, and naturally the need for establishing a station at a height where it is convenient to work throughout the year has been felt. The Meteorological Department has a station at Kodaikanal (about 7,000 ft.) in southern India, close to the geomagnetic equator. The geographical position of India for the study of cosmic rays is of special importance, because one can go from the geomagnetic equator to about 25° N. within a narrow range of longitude. The effects of the earth's magnetic field are strongly felt in this part of the world, for the intensity of cosmic rays varies rapidly with geomagnetic latitude within the intermediate latitudes.

Aligarh Muslim University was one of the institutions in India where work on cosmic rays was initiated in 1949. The cosmic-ray group thought it necessary to establish a station in the Himalayas at a convenient height, and, after considering various sites, it was finally decided that such a station should be located at Gulmarg in Kashmir. The Government of Jammu and Kashmir provided ample facilities for the opening of this laboratory, and a formal agreement was signed with the Government in the year 1951. The observatory was officially opened this year on April 4 by Prof. A. H. Compton, chancellor of Washington University (see *Nature*, May 1, p. 805). Spacious accommodation at Gulmarg has been provided to house the laboratory, its staff and visitors. The research observatory is run jointly by Aligarh Muslim University and the University of Jammu and Kashmir under a managing committee consisting of representatives of both these institutions. The decision to establish the observatory at Gulmarg was based on many factors, one being that Gulmarg is one of the finest hill stations in Kashmir with a very fine golf course, and another that it is easily accessible and, if need be, it is possible to keep the observatory open for the whole year. In the words of Prof. A. H. Compton: "The height of 9,000 ft. is as great as persons unaccustomed to altitude can work without discomfort, and is adequate for many types of study that cannot be performed effectively at sea-level. The altitude is comparable also with that of most of the high-altitude laboratories elsewhere with which it is important to compare results, for example, Mexico City (about the same magnetic latitude) at 7,500 ft., Huancayo, Peru, at 10,500 ft., Echo Lake, Colorado, at 10,000 ft., and Jungfraujoch, Switzerland, at 11,300 ft. The location is also suitable as a base station for work at higher altitudes, up to 11,000 ft. at Khillan Marg, one hour distant, and up to 14,000 ft. at Apharvat, three hours distant. These locations are as high as any stations at which high-altitude research is now regularly being done".

The research observatory is easily accessible, and a 'jeep' can go right up to the gate of the observatory. To get to Gulmarg, one can fly from Delhi to Srinagar, the capital of Kashmir, the flight lasting three hours, and from Srinagar Gulmarg is twenty-eight miles away. Alternatively, there is a train service up to Pathankot, from where one can take a bus to cover the 275 miles to Srinagar. A good road goes from Srinagar to Tangamarg, which is within four miles of Gulmarg, and this road is now being extended for 'jeeps' and trucks right up to Gulmarg. The proposed tunnel under the Banihal Pass will keep the road open to Srinagar throughout the year.

The physical details of the observatory are as follows: altitude, 9,000 ft.; geographic latitude, 34° 03′; geomagnetic latitude, 24° 36′; geographic longitude, 74° 24′; average barometric pressure, 707 mb.; maximum temperature, 80° F.; minimum temperature, 30° F.; and average temperature, 60° F. At present the electric power is not satisfactory, as the supply only allows for 5 kW. and the load is such that the voltage fluctuates considerably; also, the alternating frequency is 25 c./s. The Kashmir Government intends to instal a new generator which will give 220 V., 60 c./s., within a few years. During the working season, Nedou's Hotel remains open to visitors, and there are also a number of small hotels and eating places. There is a market for buying provisions. Horses, ponies and labourers are available in abundance at fairly reasonable rates.

The resources of the observatory are meagre, as the two co-operating universities are unable to provide adequate funds at present. It is hoped that in due course a small workshop will be installed. The managing committee of the observatory has empowered the director to allow Indian and foreign investigators to carry out work at this altitude and latitude, if such requests are made. It is intended to develop the observatory into a general-purpose high-altitude laboratory; though it is not meant solely for the cosmic-ray studies, this is the main field in which work has been in progress.

SOCIAL FEEDING BEHAVIOUR OF BIRDS

AUSTIN L. RAND, of the Chicago Natural History Museum, has published a paper with the object of illustrating how certain behaviour patterns in birds may have originated out of general tendencies and evolved from simple to complex patterns (*Fieldiana: Zoology*, 36, No. 1). Social feeding habits of birds, outside the breeding season, are considered from the point of view of possible stages through which the more complex patterns have evolved. Behaviour patterns are examined and compared, and arranged according to their similarity in organization and usefulness. This discloses a number of series, each starting with the simple and becoming more and more complex.

Intraspecific social behaviour is examined first, as it is simpler, and the factors involved tend to be more easily seen. Gregariousness is very pronounced in birds, and seems to be the main starting point for these associations. This flocking could be a disadvantage when food is limited; but various modifications or organizations of the flocks exist that not only cancel out such disadvantages, but also make a position in the organized flock more advantageous than solitary feeding. The most obvious of these are: spacing out of the flock to reduce competition; the leading of some individuals to food by others going to it; the beating or driving of coverts, which flushes prey into accessibility; combining of individuals to capture, kill or otherwise secure food already sighted.

The feeding associations of birds transcend species limits, and many are concerned with animals other than birds, including man and his extensions such as ships. The bird seeking the association is often the chief beneficiary, through the beating activities, the providing of scraps, and the providing of parasites and even flesh of its own body by the animal accompanied. Another series in this category is the pilfering or robbing of one species by another.

In flocks in which numerous species of birds keep together, many of the factors involved in the simpler cases mentioned above are discernible, and it is probable that several may work together, reinforcing each other. Protection from predation by flocking is probably of no great importance.

Data are given to show the extreme acuity of birds in seizing on small elements in their environment that provide food benefits. They show that such occasional benefits may lead to new habits; that new habits are still arising; and that simple or occasional associations in some species are more complex or regular in other species.

It is possible to see how complex behaviour patterns evolved if psychological processes of a low order are postulated, satisfaction or benefits being associated with the presence of certain conditions such as variability among the birds to recognize such associations and the selection of certain favourable variations until they become a part of the normal behaviour pattern.

The rapidity with which new patterns develop, and similar patterns that evolve in unrelated birds, indicate that these behaviour patterns are not necessarily phylogenetic. Despite this, these patterns indicate the stages through which complex behaviour probably passed and how it originated.

Some mixed bird parties increase competition between species, offsetting some at least of the mutual aid of the associations.

MICROSEISMS

THE name microseisms was given in 1870 by Father T. Bertelli to the ground unrest of wave period from about 1 sec. to 10 sec. and variable amplitude (about 5 μ) registered by seismographs. This movement is now studied because of its intrinsic interest and also pragmatically because of its meteorological associations. A symposium on the subject, organized by Dr. R. C. Gibbs, was held at Arden House, Harriman, New York, during September 4–6, 1952, under the sponsorship of the Office of Naval Research and the Geophysical Research Division of the United States Air Force[*]. It was attended by more than thirty specialists in the field (one each from the Netherlands and Sweden, two from Great Britain and the remainder from the United States), and the report has just been received. It contains the following eight papers together with the discussions on them: sketch of the history of microseismology, by J. B. Macelwane, *S.J.*; tripartite stations and the direction of approach of microseisms, by J. E. Ramirez, *S.J.*; amplitude distribution of storm microseisms, by Marion H. Gilmore; microseismic period spectra and related problems in the Scandinavian area, by Marcus Båth; Can sea waves cause microseisms ?, by M. S. Longuet-Higgins; storm and surf microseisms, by F. W. van Straten; the ocean as an acoustic system, by Frank Press and Maurice Ewing; on theories of the origin of microseisms, by J. G. Scholte.

It appears to be generally accepted that microseisms, more frequent in winter than in summer, are elastic waves travelling at about 100 miles/min. over the surface of the earth and not body waves through the earth. They appear to be largely Rayleigh waves together with some Love waves, and to be of different wave forms as well as of different periods. Those of period 2 sec. and less may be due to local winds or may be man-made. Group microseisms of period 3–10 sec., exhibiting beats, appear to be almost always of marine origin, and those of period 1 min. or more to occur at the time of frost near stations. The symposium was mostly concerned with problems about the group microseisms of period 3–10 sec.

Historically, it was suggested by Wiechert that these may be due to the beating of surf on a rocky coast, and later by others that they were formed near the centre of a storm at sea. Tripartite stations were used by J. J. Shaw in England (1918–22) and more accurately by Gilmore, among others, in the Caribbean (1944) to get cross-bearings, in an attempt to track the centres of microseismic disturbances. This method has not proved entirely satisfactory, supposedly because of geological barriers such as deep-seated faults, and the irregular passage and attenuation of waves by geological formations. Gilmore is now attempting to detect microseismic centres when they begin; to follow the centres once they have formed; and to get an idea of the energy at all points in the path, by empirical amplitude relationships.

The intimate connexion between events in air (such as microbarometric pulsations, gustiness, barometric gradients and cold fronts), events in the sea (waves, standing waves, surf pressure) and microseisms is not fully understood, but good progress is being made at some points. It has been shown by Deacon and Longuet-Higgins, following work by Miche, that second-order terms in the equations of the pressure field produced by standing waves at sea integrated over a sufficiently large area could quantitatively account for microseisms of half the period of the standing waves; and such microseisms have been shown to exist at Kew. Ocean waves of period 16 sec. produced 8-sec. microseisms at Kew, just as ½-sec. waves in an experimental tank produced ¼-sec. microseisms in the bottom of the tank.

Standing waves in the ocean could conceivably be produced by interference caused by a fast-moving low air pressure area, or by coastal reflexion of ocean waves; but this does not seem to be the whole picture since, on the western side of the Atlantic Ocean, Frank Press and Maurice Ewing (Columbia University) conclude from their observations that "(1) Frontal microseisms are generated very soon (often abruptly) after a cold front passes seaward from land, with no obvious correlation to prior wind and sea conditions. (2) A relatively narrow spectrum of periods appears to be generated by a front, cyclone, or hurricane at a given time when the disturbance is over an area of uniform water depth. Characteristic periods of microseisms can be related to generating areas in the ocean. (3) As a front recedes from shore, the spectrum gradually shifts to longer periods, and becomes fairly constant after deep water is reached. (4) Cold fronts and air masses following them can generate microseisms whereas warm air masses preceding the cold fronts fail to generate microseisms even when strong onshore winds are present. (5) In many cases there are no obvious correlations between swell and surf conditions and microseisms. (6) Microseismic energy is dissipated by a profound crustal discontinuity at the edge of the continental shelf. Hurricanes crossing the edge suddenly generate larger microseisms".

---

[*] Symposium on Microseisms. (Publication 306.) Edited by James T. Wilson and Frank Press. Pp. vii+125. (Washington, D.C.: National Academy of Sciences, National Research Council, 1953.) 1 dollar.

Observations are still being made at observatories throughout the world, in conformity with the microseismic research project of the Section of Seismology of the International Geodetic and Geophysical Union, which was initiated in 1952, and detailed observations have yet to be made of the energy of the gusts of wind at sea likely to be associated with microseisms, and also the pressures and variations of pressure at great depths on the bottom of the ocean likely to be associated with microseisms. It is hoped that, with further observations and consideration, more progress will be made, particularly with the air–sea energy transfer.

ERNEST TILLOTSON

BASIC RESEARCH ON ODOUR

To say that the sense of smell has been neglected as an object of study, because of the formidable experimental difficulties involved, particularly when examining the peripheral aspects of the sense, is of course to state a platitude. It would appear that the newer techniques of measuring minute quantities of substances might, however, prove rewarding when applied to the investigation of olfaction, and might be the means of stimulating renewed interest, especially in these neglected peripheral phases. It was possibly with such thoughts in mind that a conference was organized in April 1953, jointly by the New York Academy of Sciences and the American Society of Heating and Ventilating Engineers, for although practically every aspect of olfaction was then reviewed, greatest emphasis was placed on the peripheral phases. The edited versions of the papers read at the conference have now been published in the *Annals of the New York Academy of Sciences*[*]. No doubt because of the participation of the latter Society, papers on technological problems occupy a prominent place, more prominent than would probably be the case at a similar conference in Britain. The whole report, therefore, provides an up-to-date review, and a short guide to the literature, of both technical and laboratory work carried out recently on odours and olfaction.

A major object of any conference such as this is to throw up ideas, and a reasonable degree of speculation is not altogether undesirable. However, this can be overdone, and unfortunately several of the participants did not resist the temptation to explain how, on theoretical grounds, odours might be converted into nerve impulses. While reading some of the papers, one was reminded of Homer Smith's comment, made when he was reviewing the earlier concepts of renal function, that the history of science has been one of rival over-simplified theories, to which fault has been added that of insufficient experimental work. Parts of the report on this conference show that our grandfathers may have been no worse than ourselves.

The first part of the conference was concerned with the problem of odour in industry; the papers were, in fact, devoted to the practical problems of how to prevent food, tobacco, paper and the interiors of buildings from being contaminated by odoriferous substances. As there is so little basic knowledge available as to either the behaviour of the odoriferous substances, or the absorbent properties of the contaminated materials, the problems are attacked along empirical lines. The cause is traced, and if it cannot be removed then various odour neutralizers or modifiers are tried until the one which is most satisfactory in the circumstances has been found.

The next major section of the conference was entitled "Problems of Odour Research from the Viewpoint of the Scientist", with contributions from a physiologist, a psychologist, a physicist and a chemist. J. Greenspan outlines some of the newer physical methods for measuring concentrations as low as parts per million; but later in the conference, R. L. Kuehner reports that such methods are still not as satisfactory as would be desired, and he suggests the use of other methods which depend upon subjective threshold sensations, or upon chemical absorption of the odorant. L. M. Beidler, the physiologist, points out, too, that by analogy with the investigations on taste a method of measuring concentrations in the air, and of controlling such concentrations, would not necessarily enable the ultimate nature of the stimulus to be understood, for the nature of the receptor is so important. J. B. Sumner, at least, is aware that the generally accepted view of odours being transmitted by volatile particles in the atmosphere is no more than a hypothesis, although undoubtedly a much more satisfactory one than others depending upon such an alternative as infra-red radiation.

The third section was concerned with the status of our present knowledge of the olfactory nervous system, and contained papers of rather uneven quality. There was in one paper a tabulated list of the functions of the turbinate bones; while another paper, which offered yet a further hypothesis of olfaction, based upon information theory this time, opened with a quotation followed by the comment, "In these words, Titus Lucretius Carus developed the first atomistic theory of olfaction in about 47 B.C. This year of 1953 marks the two-thousandth anniversary of this theory". On the other hand, K. H. Pribram and L. Kruger's review of the "Olfactory Brain" is particularly satisfying, and, at the risk of appearing invidious to the writers of other equally satisfactory articles, one may regard it as one of the most important papers of the conference and suggest that it is not to be overlooked. Their final conclusion justifies quoting: ". . . the 'olfactory brain', as defined, is not primarily olfactory, though parts of it serve olfactory functions. Nor is the current conception of a 'visceral brain' more tenable though visceroautonomic functions are also served. It is clear that the formations in this portion of the brain, though they share several characteristics, are not, at this time, usefully thought of as *a* brain serving any *one* function. Since at least three distinct systems can be delineated, each might profitably be investigated before an attempt is made to define what functions they have in common". In the third section also, M. M. Mozell and C. Pfaffman contribute a review of the afferent neural processes, largely concerned naturally with Dr. E. D. Adrian's recent work, while V. G. Dethier has a most interesting paper on the physiology of olfaction in insects.

The rest of the conference was mainly devoted to techniques of measuring and identifying odours, with a consideration of some of the results obtained. This section might preferably have been placed earlier in the conference. Most of the workers concerned with the practical problems of eliminating odours prefer to use subjective methods; but there is here also a full discussion of objective methods. It has been suggested that the olfactory mucosa is sensitive to concentrations as low as 10^{-13}; if this is true, there is some considerable way to go, and much fundamental research is required, before adequate objective methods are available. But this is not to deprecate the very valuable and important work of the present-day pioneers.

H. SOSNOWICK

AGE OF PARENT AND CHARACTER OF OFFSPRING

THE relations of an offspring to its parents are complex, and the ways in which a parent may influence the character of its offspring are many. This is especially true among the higher animals; but even when we turn to lower animals and to plants the parent–offspring relation, if simpler, is still far from simple. Though, as genetics has emphasized, the primary endowment is the complement of nuclear genes, an individual also receives from its parents its initial cytoplasm—mainly, but not necessarily exclusively, from its mother. The cytoplasm so received may contain particles of a genetic or semi-genetic nature (plasmagenes of various kinds), nutritional materials, protective substances and agents of disease (such as viruses). It is a complex endowment as yet by no means fully understood. Nor is the cytoplasm the only avenue of supply of food materials, protective substances and disease risks. The close association of offspring with parent during early life, especially in higher animals, plays its part in the nutrition, protection and disease relation of the offspring and, of course, also in its education.

Our understanding of these various links between the generations is not equal. Classically the geneticist has concerned himself primarily with the nucleus and the genes it carries, setting other aspects aside as secondary to the main problem. Initially this was an essential restriction, but of recent years especially the study of the nuclear genes has itself guided attention to the cytoplasm, to the immunological relations between mother and child, and to the effects of maternal nutrition; indeed, to the whole complexity of the parent–offspring relation. Thus as the genetical framework has become clear, the way has opened up to a co-operative attack on the broader problem by all the many interests which are concerned.

Both the complexity of the problem and the many types of approach which can be made to it are brought out by a recent symposium on "Parental Age and Characteristics of the Offspring" held by the New York Academy of Sciences*. Although in his introduction E. V. Cowdry chiefly emphasizes the effects of age of mother and father on longevity in the offspring, he recognizes in his summary that this provides only a superficial common denominator for the many phenomena described in the nineteen contributions to the symposium, and he stresses the need for a better understanding of the mechanisms which underlie the effects we observe. The observations reported cover a very wide field. Asexually produced progeny in plants are discussed alongside parthenogenetic rotifers and the sexual offspring of mammals. Longevity, germination characters of seeds, mutation-rates, the expression of congenital malformation in men and mice, mongolism and the sex ratio in man, fibrocarcinoma and leukaemia in mice, the consequences of ageing gametes before fertilization, skeletal characters, spotting, the results of altering a mother's physiology during pregnancy, and seasonal influences, are all to be found among the subjects considered. As might be expected, the importance of the mother's age emerges clearly as opposed to that of the father; but there is, again not surprisingly, little pattern to be discerned as yet even at the level of description of the phenomena. Suggestions can be, and are freely, made as to the underlying causation. Hormonal changes, cytoplasmic entities, antibody levels, viral effects, biochemical adjustments, and alterations in crossing-over with age, are all brought in, and the susceptibility of polygenically determined variants to non-nuclear effects is emphasized. But the value of this symposium lies in the problems it poses and the clues it offers rather than in the explanations it achieves or the mechanisms it exposes.

Two papers are especially interesting in their bearing on the nature of somatic ageing. The first, by A. I. Lansing, describes experiments with the rotifer *Philodrina citrina*, which, being parthenogenetic, is unlikely to show any significant amount of variation mediated by nuclear genes within its progenies. Separate lines were developed, differing in the age of the mother at the time of production of the eggs from which the next generation was raised. With eggs from adolescent mothers the longevity of the offspring tended to increase as the generations went by. The lines in which eggs were taken from middle-aged or senile mothers, on the other hand, showed a decline in longevity until they died out after five and three generations, respectively. The change is reversible by reversal of the selection. Furthermore, there is a close relation between growth and ageing, the ageing factor appearing in the eggs at the time when the mother ceases growth. Accelerated ageing accelerates growth but decreases maximal size, while retarded ageing retards growth and increases maximal size.

In the second paper E. Ashby and E. Wangerman describe experiments with clones of the water-plant *Lemna minor*. The fronds of this plant reproduce by asexual buds, the daughters so produced being successively smaller as the mother frond ages. It appears from extrapolation that the age of mother at which daughter size would be zero is the age of death. Thus the meristems grow old with the mother. As with the rotifers the process is cumulative and reversible, for first daughters are larger than their mothers where these mothers were themselves from old parents and therefore small.

The regularity and similarity of behaviour in the rotifer and the plant are striking. Though clearly not dependent on genetic segregation, the responses to selection resemble in several respects those which can be obtained with polygenic variation. Can they depend on a multi-particulate cytoplasmic system, related ultimately to the nucleus, but capable of change independently of the nuclear genes? Though it is too early to do more than speculate, these papers suggest an experimental approach which might materially advance our understanding of the changes which go on during development and ageing.

INCORPORATION OF HALOGENATED PYRIMIDINES INTO THE DEOXYRIBONUCLEIC ACIDS OF *BACTERIUM COLI* AND ITS BACTERIOPHAGES

THE pyrimidine 5-bromouracil may be regarded as a structural analogue of thymine in which the methyl group of thymine is replaced by a bromine atom. Weygand, Wacker and Dellweg[1] showed that the inhibition of growth of *Streptococcus faecalis* R. by 5-bromouracil is competitively reversed by thymine. Using 5-bromouracil containing the isotope bromine-82, they demonstrated the incorporation of 5-bromouracil into the nucleic acids of *S. faecalis*, although they did not show whether the analogue was present in the ribonucleic or deoxyribonucleic acids.

We have found that, under conditions in which *Bacterium coli* requires thymine, 5-bromouracil and 5-iodouracil are extensively incorporated into the deoxyribonucleic acids of the bacterium and its bacteriophages, replacing thymine residues in the nucleic acid molecule. No incorporation of 5-bromouracil into the bacterial ribonucleic acid could be detected.

B. coli strain *B* was grown in a glucose – ammonium sulphate medium containing sulphanilamide (1 mgm./ml.), vitamin-free casein hydrolysate (1 mgm./ml.), xanthine (25 µgm./ml.) and varying amounts of thymine. In this type of medium, growth of *B. coli* has been found to be dependent upon the amount of thymine[2]. Two to four hours after the addition of 5-bromouracil or 5-iodouracil, the mean generation time of bacteria in this medium is increased and thereafter remains approximately constant. The degree of inhibition by 5-bromouracil increases with the ratio 5-bromouracil/thymine; but is not affected by uracil. After inhibition by either analogue, the proportion of bacteria giving colonies on nutrient agar is reduced.

The bacteriophages T_2r and T_1 were grown on *B. coli B* in the above medium containing 8×10^{-6} *M* thymine by infecting with three bacteriophages per bacterium at a bacterial density of $1{\cdot}5 \times 10^{8}$/ml.; 2×10^{-3} *M* 5-bromouracil or 5-iodouracil was previously added at a bacterial density of 10^{8}/ml. Although it has been reported that in a similar medium *B. coli* infected with T_2, T_4 and T_6 bacteriophages fails to lyse[3], under our conditions 90 min. after infection with T_2r the bacteria lysed with the production of bacteriophages. T_2r was purified by the method of Herriott and Barlow[4] and T_1 by differential centrifugation and treatment with deoxyribonuclease.

Deoxyribonucleic acid was prepared from *B. coli* by the method of Smith and Wyatt[5] and from T_1 by treatment with 0·1 *M* sodium citrate buffer *p*H 7 at 45°. Intact T_2r bacteriophage and deoxyribonucleic acid from *B. coli*, both grown in the presence of 5-bromouracil, were hydrolysed in 72 per cent w/w aqueous perchloric acid[6] and the hydrolysates run on two-dimensional paper chromatograms in *iso*propanol – water – hydrochloric acid[7] and *n*-butanol – water – ammonia[8]. In both hydrolysates, 5-bromouracil, identified by paper chromatography, electrophoretic mobility and ultra-violet spectroscopy, was found to have replaced quantitatively part of the thymine found in normal T_2r and *B. coli* nucleic acids (Table 1). The relative proportions of the other bases remained unchanged.

Table 1. MOLAR PROPORTIONS OF THYMINE AND HALOGENATED PYRIMIDINES IN DEOXYRIBONUCLEIC ACIDS FROM *B. coli* AND T_2r GROWN IN THE PRESENCE OF 5-BROMOURACIL AND 5-IODOURACIL

The nucleic acids were hydrolysed in perchloric acid, and in the case of T_2r, Wyatt's data (ref. 9) were used to allow for the 5-hydroxymethyl cytosine.

Deoxyribonucleic acid	Moles/100 moles estimated bases Thymine	5-Bromouracil	5-Iodouracil (estimated as uracil)	Thymine + halogenated pyrimidine
B coli B	27·2	—	—	27·2
B. coli B '5-bromouracil'	16 0	8 7	—	24 7
B. coli B '5-iodouracil'	19 4	—	4·5	23·9
T_2r	30·5	—	—	30 5
T_2r '5-bromouracil'	6 4	24 1	—	30 5
T_2r '5-iodouracil'	15 4	—	14·5	29 9

Deoxyribonucleic acids from *B. coli* and T_1 grown in the presence of 5-bromouracil were hydrolysed to the 5′ nucleotides with deoxyribonuclease and rattlesnake venom diesterase. The separation of 5-bromouracil deoxyribonucleotide was facilitated by the fact that 5-bromouracil bears a negative charge at *p*H 9 (presumably due to the dissociation of the 2 or 6 (OH) group) while the other bases are uncharged. Paper electrophoresis of both hydrolysates in 0·05 *M* borate buffer *p*H 9 gave, in addition to a band containing the four natural nucleotides, a second band migrating more rapidly towards the anode. This contained a substance with an ultra-violet absorption spectrum in 0·1 *N* hydrochloric acid similar to that of 5-bromouracil but shifted about 3 mµ towards the longer wave-lengths (λ max., 279 µ; λ min., 244 µ). On hydrolysis with perchloric acid, this gave 0·96 mole 5-bromouracil/mole phosphate. We conclude that the substance is 5-bromouracil deoxyribonucleotide. After hydrolysis of the *B. coli* deoxyribonucleic acid with deoxyribonuclease and snake venom diesterase and 5′ nucleotidase, a substance with the expected properties of 5-bromouracil deoxyriboside was isolated.

Perchloric acid hydrolysis of T_2r bacteriophage or deoxyribonucleic acid from *B. coli* grown in the presence of 5-iodouracil gave in addition to the usual bases a substance identified by chromatography and ultra-violet spectroscopy as uracil. The relative proportion of thymine to the other bases was decreased such that the sum of the uracil and thymine equalled the expected amount of thymine (Table 1). It was then found that 5-iodouracil, although stable alone to the perchloric acid hydrolysis, in the presence of deoxyribonucleic acid preparations is converted to uracil. Enzymic hydrolysis of the *B. coli* deoxyribonucleic acid followed by paper electrophoresis at *p*H 9 gave a substance with the expected electrophoretic mobility and ultra-violet absorption spectrum of 5-iodouracil deoxyribonucleotide. On hydrolysis with perchloric acid this decomposed giving uracil. While as yet lacking direct evidence from the isolation of iodouracil itself, we conclude that the uracil found in the perchloric acid hydrolysates of the deoxyribonucleic acids is derived from 5-iodouracil incorporated into the nucleic acids. We have also found that 5-chlorouracil will replace thymine residues in the deoxyribonucleic acid of thymine-requiring *B. coli*.

Preparations of T_2r and T_1 containing 5-bromouracil or 5-iodouracil had the same ultra-violet absorption spectra as normal preparations, and electron microscopical examination of the T_2r 'bromouracil' preparation showed particles of normal structure. However, the ratio (bacteriophage titre/optical density at 260 mμ) showed that the various 'bromouracil' and 'iodouracil' bacteriophage preparations contained 50–98 per cent non-infective particles. For example, in a preparation of T_2r in which 79 per cent of the thymine residues were replaced by 5-bromouracil, 70 per cent of the particles did not give plaques when plated on *B. coli B*.

As 5-bromouracil or 5-iodouracil was present before and after infection, it is reasonable to assume a nearly random distribution of halogenated pyrimidine residues among the bacteriophage particles. It thus seems likely that particles containing 5-bromouracil and 5-iodouracil are infective, but that the probability of successful infection by a virus particle decreases with increasing incorporation of the analogue.

The incorporation of bromine and iodine atoms into specific positions in the deoxyribonucleic acid molecule may be of considerable help in elucidating its structure by means of X-rays. This possibility is being investigated by Dr. M. F. Wilkins and his colleagues at King's College, London.

The hypothesis that the composition of the whole deoxyribonucleic acid is characteristic of the species from which it was derived[1] does not necessarily imply that this composition is unchangeable. However, the constancy of composition in cumulative data (for a review see ref. 2), as well as the finding that the deoxyribonucleic acid of a thymine-requiring strain of *E. coli* does not change its thymine content when the cells were grown on a large excess of thymine[3], strongly suggested that the composition of deoxyribonucleic acid is independent of the environment, as, it seemed, would need to be the case for a heredity determinant.

The findings[4–8] that the unnatural purine azaguanine and pyrimidine thiouracil can be built into ribonucleic acid prompted investigation into the possibility of such building into deoxyribonucleic acid. With purines (azaguanine, 6-mercaptopurine), the incorporation, if any, was extremely low[6,7,8]. On the other hand, Weygand *et al.*[10] found that a mixture of degradation products of deoxyribonucleic and ribonucleic acids from *S. faecalis R*, grown on a medium containing the radioactive unnatural pyrimidine 5-bromouracil containing bromine-82, yielded on hydrolysis a radioactive substance or substances of a chromatographic R_F value (butanol – water) similar to that of both thymine and 5-bromouracil. These investigators suggested that the 5-bromouracil, due to its steric similarity to thymine, was indeed built into deoxyribonucleic acid of *Streptococcus faecalis*. Radioactive 5-bromouracil was also taken up by non-dividing cells of *Streptococcus faecalis* and *Enterococcus* Stei, but little, if any, was taken up by *E. coli*[11].

† For strain II, recovery 92 per cent of nucleic acid phosphorus; guanine recovery was least satisfactory.

We have grown certain strains of *E. coli* on a medium containing 5-bromouracil and have isolated highly polymerized deoxyribonucleic acid in which 18–28 per cent of the thymine was replaced by 5-bromouracil. Strain I was the thymine-requiring mutant mentioned above[3]; strain II was a back-mutant to thymine independency. The behaviour of these strains is described in the following communication.

The cells were grown at 37° on nutrient agar or broth containing 5-bromouracil (100 μgm./ml.). This addition partially inhibits the growth of strain I but not of strain II. Highly polymerized deoxyribonucleic acid was isolated by two methods (Table 1): (*a*) from strain I by the method previously described[3]; (*b*) and (*c*) from strain II by a modification in which grinding is replaced by incubation with 3 *M* glycine followed by three extractions with 1 *M* aqueous sodium chloride; only the latter extracts were used for the recovery of deoxyribonucleic acid. In this method two preparations were made: (*b*) not treated with 'Norit' and not dialysed; it contained 10 per cent ribonucleic acid; and (*c*) treated with 'Norit' and dialysed as described before[3]; it contained less than 1 per cent ribonucleic acid.

The final viscous preparations were precipitated with ethanol; the fibrous precipitate in 3 mgm. aliquots was hydrolysed for 40 min. at 100° with 0·08 c.c. of 7·5 *N* perchloric acid[12], diluted to 0·2 ml., centrifuged and analysed by paper chromatography in two solvent systems: (1) in butanol – water the ratio $\frac{R_F \text{ 5-bromouracil}}{R_F \text{ thymine}}$ is 1·04; this usually does not permit the separation of these two compounds (compare ref. 10), but permits the separation of the two from other nitrogenous bases; (2) in butanol – ammonia the ratio $\frac{R_F \text{ 5-bromouracil}}{R_F \text{ thymine}}$ is 0·49; this permits easy separation of the two. Accordingly, the hydrolysate was first chromatographed in system (1), and the common spot of 5-bromouracil and thymine was then chromatographed in system (2); this was accomplished technically by using either two-dimensional chromatography, or a long strip of paper in step (1).

The final spots were extracted and the nitrogenous bases content determined in the Beckman spectrophotometer. The hydrolysate of deoxyribonucleic acid of strains I and II grown on 5-bromouracil exhibited a spot (located by means of an ultra-violet lamp and special fluoroscope[13]) which in both solvent systems behaved exactly like pure 5-bromouracil, and, when extracted, showed an ultra-violet absorption spectrum identical with that of pure 5-bromouracil (in water, E max. at 276 mμ ; $E(276)/E(290) = 1 \cdot 57$; in 0·1 N sodium hydroxide, E max. at 296 mμ). In addition, this extract containing 10 μgm./ml. base computed (ultra-violet spectrum) as 5-bromouracil inhibited the growth of strain I to the same extent as did pure 5-bromouracil (for details see following communication).

The results are summarized in Table 1. It can be seen that the thymine content was approximately a quarter to a third less (on cytosine basis) than in this and two other *coli* strains grown in the absence of 5-bromouracil (in which molar ratios of individual bases are close to 1[3]); this amount seems to be substituted by bromouracil (28–18 molar per cent of cytosine).

In such a study it is, of course, necessary to exclude rigorously the possibility that the 5-bromouracil was present in deoxyribonucleic acid merely as a non-chemically bound impurity. This possibility is contra-indicated by the corresponding deficiency in thymine ; other control experiments are listed below :

(1) Normal deoxyribonucleic acid was dissolved in aqueous solution containing 5-bromouracil (100 μgm./ml.) and subjected to purification procedures for deoxyribonucleic acid, as described above. The hydrolysate of the final product contained no detectable 5-bromouracil.

(2) As can be seen from Table 1, the 5-bromouracil content of the dialysed (48 hr.) preparation (*c*), which contains less than 1 per cent of ribonucleic acid, is the same as that of the non-dialysed preparation (*b*), which contains 10 per cent ribonucleic acid ; this makes it improbable that the bromouracil was present as a low molecular-weight component or as a component of ribonucleic acid.

(3) Prior to hydrolysis at 100° for 40 min. the deoxyribonucleic acid of strain II was hydrolysed (with 7·5 N perchloric acid) for ½ hr. at 37°. This procedure liberates all purines but no cytosine and only 4 per cent of thymine. No 5-bromouracil could be detected in the hydrolysate. The 5-bromouracil was liberated only after hydrolysis (100°, 40 min.), liberating pyrimidines from deoxyribonucleic acid. (Ribonucleic acid pyrimidines are little liberated in these conditions).

(4) The presence of 5-bromouracil as an integral component of deoxyribonucleic acid was suggested by the actual isolation of 5-bromouracil deoxyriboside. 25 mgm. of deoxyribonucleic acid (preparation *b*, Table 1) were digested for seven days at 30° with the malt nuclease preparation[14] which was recently found to produce deoxynucleosides in good yield[15]; the conditions were those employed in the latter paper. The digest was concentrated and analysed chromatographically as described above. Besides natural deoxyribosides, the chromatograms showed in both solvent systems an additional spot of R_F value similar to that of 5-bromouracil. The extract of this spot showed the presence of a deoxypentose[16]; the ultra-violet absorption spectrum exhibited a maximum at 279 mμ which, like thymidine[17] (but unlike thymine or 5-bromouracil), did not shift to higher wave-lengths in 0·1 M sodium hydroxide (E max. at 277 mμ). In addition, this extract containing 0·5 μgm./ml. nucleoside computed (ultra-violet spectrum and deoxypentose content) as 5-bromouracil deoxyriboside inhibited the growth of strain I (see following communication).

When the extract was hydrolysed with 7·5 N perchloric acid at 100° for 40 min., it yielded a substance identified as 5-bromouracil by its chromatographic behaviour, ultra-violet absorption spectrum, shift of spectrum in 0·1 N sodium hydroxide, and bacterial growth inhibition, as described above. All these data indicate that the unknown (before hydrolysis) was indeed 5-bromouracil deoxyriboside.

E. coli containing 5-Bromouracil in its Deoxyribonucleic Acid

IN the preceding communication we have reported that certain strains (I and II) of *E. coli*, when grown on a medium containing 5-bromouracil, build this unnatural pyrimidine into cellular deoxyribonucleic acid. Strain I was isolated[1] by one of us (S. Z.) from American Type Culture Collection No. 11117 ; the latter is a mutant produced by X-ray irradiation[2]. Strain I requires thymine for growth on a synthetic (asparagine) medium. It has been used for the thymine assay[3] and for the study of the effect of excess of thymine on thymine content in deoxyribonucleic acid[4]. Preliminary study[1] indicated that the thymine requirement can be replaced by thymidine or thymidylic acid but not by other natural constituents of deoxyribonucleic and ribonucleic acids.

We find that 8×10^{-7} M (0·1 μgm./ml.) thymine, 2×10^{-7} M thymidine and 2×10^{-6} M thymidylic acid represent minimum growth requirements on a synthetic medium. This may indicate that also in these strains thymidine is a more direct precursor of deoxyribonucleic acid than the other two compounds. The following compounds in concentration 100 μgm./ml. (unless otherwise stated) do not support growth : 5-bromouracil, 5-bromouracil deoxyriboside, 5-aminouracil, 2-thiothymine, 5-ethyluracil (from Dr. G. Elion, Wellcome Research Laboratories), 2-thiouracil, 6-azathymine (from Dr. W. H. Prusoff, Yale University), 5-nitrouracil, alloxan, veronal, barbituric acid, orotic acid, 6-methyl uracil, dihydrothymine, folic acid (1 μgm./ml.), vitamin B_{12} (50 μgm./ml.), thymidine diphosphate, 1-methyl thymine (from Dr. L. Cavalieri, Sloan-Kettering Institute for Cancer Research), 1-methyl-4-ethoxythymine (from Dr. L. Cavalieri), 2,4 diethoxy-thymine (from Dr. L. Cavalieri) (the last four compounds 10 μgm./ml.). In the presence of 1 μgm./ml. thymine, the above compounds (in concentrations stated) also do not inhibit growth, except for the first five, which inhibit growth for at least 48 hr. when present in the following (or higher) concentrations: 5-bromouracil (10 μgm./ml.); 5-bromouracil deoxyriboside (0·5 μgm./ml.); 5-aminouracil (100 μgm./ml.); 2-thiothymine (100 μgm./ml.); 5-ethyluracil (200 μgm./ml.). Uracil[1] and 2-thiouracil inhibit only at concentrations higher than 200 μgm./ml.

In the presence of 1 μgm./ml. thymidine, 5-bromouracil (100 μgm./ml.) does not inhibit growth; this again may indicate that thymidine is a more direct precursor of deoxyribonucleic acid than thymine. Very strong inhibition of thymine by 5-bromouracil deoxyriboside also points in this direction.

5-Bromouracil (100 μgm./ml.) partially inhibits the growth on nutrient agar. After 48 hr., a secondary growth (papillæ) appears containing mutants having various degrees of resistance to 5-bromouracil. On normal nutrient agar some of these mutant strains appear normal, whereas others form very small colonies.

By growing strain I on a synthetic medium, fortified with 0·02 per cent of 'Proteose Peptone No. 3' (Difco) (suboptimal growth) for more than 48 hr., the back-mutants to complete thymine independence can be isolated. One such back-mutant population consisted of 95 per cent cells inhibited by 10 μgm./ml. thymidine and 5 per cent cells non-inhibited: the latter were isolated and designated strain II (see preceding communication.)

Strain II, which exhibits full growth on a synthetic medium, is not inhibited by 100 μgm./ml. 5-bromouracil, but shows weak inhibition by 500 μgm./ml. of this compound.

Growth inhibition of *Lactobacillus casei* by 5-bromouracil was discovered by Hitchings *et al.*[5]. The inhibition by this compound in strain I can be reversed by increasing the concentration of thymine and is truly competitive against thymine. The mechanism may involve competition for the enzymes, such as the nucleoside-forming enzyme (thymidine phosphorylase[6]); as mentioned above, when thymidine is supplied, the 5-bromouracil indeed does not inhibit. In mammalian tissue, this enzyme synthesizes 5-bromouracil deoxyriboside fully half as readily as thymidine[8]. In our experiments the inhibition index of 5-bromouracil *vs.* thymine in strain I was 2·5 (16 hr.). In strain I both metabolites come from outside; in strain II, thymine is manufactured in the cell; this may explain the two hundred times lower inhibitory effect in strain II.

5-Bromouracil deoxyriboside (if indeed an intermediate) may also be less readily utilized for the synthesis of deoxyribonucleic acid; hence strong inhibition by this nucleoside. The possibility that the deoxyribonucleic acid containing 5-bromouracil participates less readily in the activities of the cell in strain I also cannot be entirely excluded.

More interesting is the finding that the 5-bromouracil can be built into deoxyribonucleic acid also without inhibition of growth. Indeed, strain II on 100 μgm./ml. 5-bromouracil builds in 17–19 per cent (on a cytosine basis) of this unnatural pyrimidine (see preceding communication); yet the speed of cell divisions remains the same as on a medium free from 5-bromouracil.

The above discussion referred to phenotypic changes In view of the possibility that the deoxyribonucleic acid is a factor in heredity, it was also interesting to study whether such a profound change in its composition, which might have occurred in most, if not all, cells, would be reflected in genotypic changes such as 'mass-mutation'. The thymine-requiring cells (strain I) had indeed entirely different colonies (flat, faint) when grown on a 5-bromouracil medium; however, they returned to normal on a thymine-containing medium free from bromine, in which thymine replaced 5-bromouracil in the deoxyribonucleic acid. The change (inhibition) ought therefore to be classified as merely phenotypic. As mentioned before, the back-mutant colonies (strain II) on a medium containing 100 μgm./ml. 5-bromouracil showed no change whatsoever. This does not preclude the induction of rare mutations by 5-bromouracil; it merely means that, in spite of its being built in rather large amounts into deoxyribonucleic acid, this unnatural pyrimidine does not induce demonstrable mass-mutations.

Thus certain changes are permissible in the deoxyribonucleic acid molecule without demonstrably affecting life of the cell; the changes are reversible; they do not demonstrably change the function of deoxyribonucleic acid as a factor in heredity (if indeed these acids are determinants in inheritance).

Obviously, these findings raise more questions. Do all deoxyribonucleic acid molecules have some of their thymine replaced by 5-bromouracil, or do some of the deoxyribonucleic acid molecules (perhaps genetically inactive) have all their thymine replaced by 5-bromouracil? What is the distribution of 5-bromouracil along the molecule? Can 5-bromouracil be built into deoxyribonucleic acid of other species[7], especially when administered as deoxyriboside? (compare refs. 6,8).

Work is in progress to determine whether unnatural bases can also be built into the deoxyribonucleic acid of unrelated strains of *E. coli* (strain *B* used as host for *T*-phage experiments; American Type Culture Collection No. 9637) and into the deoxyribonucleic acid of *Haemophilus influenzae* having transforming activity; the growth of these micro-organisms was not inhibited even by 1 mgm./ml. 5-bromouracil.

The work presented in both these communications was supported by research grants *E15* (*C7*) and *C*-1760 (*c*) from the National Institutes of Health, Public Health Service (H. E. Alexander and S. Zamenhof, principal investigators), and by an institutional grant from the American Cancer Society to Columbia University.

Nuclear Uptake of Glycine-2-^{14}C in the Newt Embryo

EXPERIMENTS with early amphibian embryos, using glycine-1-^{14}C as a tracer and the autoradiographic technique of Doniach and Pelc[1], have shown that the nuclei take up this substance into high-molecular weight compounds more rapidly than does the cytoplasm[2]. Ficq[3] has also observed a greater activity in the nuclei, using orotic acid-2-^{14}C as well as glycine-1-^{14}C. She points out that, by the neural-tube stage, incorporation has occurred in all tissues which are actively engaged in morphogenesis; and she has shown that the labelled substances were taken up into nucleic acids as well as protein.

In some recent experiments, late blastulæ of *Triturus palmatus* were kept in a solution of glycine-2-^{14}C (1·4 μc./ml.) until they reached the late yolk-plug stage, and early to mid-gastrulæ were kept similarly until the neural-plate stage. They were then fixed in 10 per cent trichloracetic acid, sectioned at 5 μ, coated with Kodak autoradiographic film and exposed for 10–35 days; after development they were lightly stained with Mayer's hæmalum. The autoradiographs of the late yolk-plug embryos show strong incorporation into the nuclei of the mesoderm, both that which had already invaginated to form the archenteron roof and that which still remained on the surface. There was also a somewhat high incorporation into the nuclei of the presumptive neural plate; but in the epidermis and endoderm there is no appreciable difference in activity between the nucleus and cytoplasm. In the neural-plate embryos, heavily charged nuclei are found in the archenteron roof and more lateral mesoderm, and also in the neural plate itself (Fig. 1). Some endoderm nuclei are beginning to be charged at this stage; but there is still no sign of high activity in the epidermis, although this is very obvious at a rather later stage in *Xenopus*[2]. We thus have clear evidence of a high metabolic activity of the nuclei, beginning in the organizer region and spreading to the neural tissue which it induces. Work is proceeding on the characterization of the substances into which the glycine is incorporated.

Partial Sex Linkage in the Mouse

THE chromosomes of *Mus musculus* have a high chiasma frequency[1], and for this reason very loose linkages are to be expected. Many of the problems of linkage and independence in this species may therefore have to be solved by cytogenetic methods rather than the breeding techniques of formal genetics.

Among them is the question whether linkage group VII is carried in the pairing segment of the sex chromosome. Partial sex linkage of two group VII mutants, *waved*-2 (*wa*-2) and *shaker*-2 (*sh*-2), was reported in 1947 by Wright[2]. However, there were two unusual features in her results, namely, (*a*) recombination was in excess of 50 per cent, and (*b*) *wa*-2 and *sh*-2 showed the same recombination with sex, though they are not closely linked. As a result, the partial sex linkage interpretation has not been universally accepted. Carter and Phillips[3] repeated Wright's experiment, but failed to find any consistent evidence of sex linkage.

With the object of obtaining evidence on questions such as this we have induced a number of translocations in the mouse, using X-rays, and have identified linkage groups involved in eleven of them. One translocation, *T*8, involves groups I and VII. The linkage with group I was found by backcrossing animals heterozygous for *T*8 and for the group I marker *chinchilla* (c^{ch}) to chromosomally normal $c^{ch}c^{ch}$ homozygotes, and testing their progeny for the semi-sterility which indicates the presence of the translocation. No recombinants were found among forty-seven tested gametes. The *c*-locus was then used for 'tagging' the translocation in further linkage tests, and was found to show close linkage with *wa*-2 and loose linkage with *Rex* (*Re*), also in group VII:

Genotypes of parents	Phenotypes of progeny			
$T8++/+c^{ch}wa\text{-}2 \times +c^{ch}wa\text{-}2/+c^{ch}wa\text{-}2$	$\frac{++}{8}$	$\frac{+wa\text{-}2}{0}$	$\frac{c^{ch}+}{1}$	$\frac{c^{ch}wa\text{-}2}{12}$
$T8++/+c^{ch}Re \times +c^{ch}+/+c^{ch}+$	$\frac{+Re}{5}$	$\frac{++}{11}$	$\frac{c^{ch}Re}{14}$	$\frac{c^{ch}+}{3}$

Translocation *T*8 thus offers a means of settling the question whether linkage group VII is sex-linked. The translocation and the sex bivalent should be cytologically recognizable in primary spermatocytes; it should therefore be possible to establish their chromosomal independence or interdependence.

This work was part of a programme carried out for the Medical Research Council.

[3] Carter, T. C., and Phillips, R. J. S., *Z.i.A.V.*, 85, 546 (1953).

Cytological study of mice heterozygous for the translocation *T*8, mentioned above by Carter, Lyon and Phillips, shows that it does not involve the sex chromosomes. The *XY*-bivalent is clearly recognizable in the accompanying microphotographs of diakinesis and metaphase nuclei of *T*8/+ males and, independent of it, the translocation figure. Analysis of the pachytene figures in the other two photographs has shown that the translocated chromosomes are the medium-sized autosomes numbered 11 and 13 in the preliminary pachytene map of the mouse[1].

It follows that loci in linkage groups I and VII in the house mouse cannot be partially sex linked.

Placental Transfer of a High Molecular Ferric Carbohydrate

In 1953, I suggested[1] that the placental transfer of iron in the rat is brought about by the placental structures building up a fairly high concentration of some hydrolysable iron compound or compounds, partly or wholly ferritin, the source of which was supposed to be the maternal serum iron. The fœtal needs for the metal were taken to determine the rate at which these intermediate placental iron compounds were mobilized. The iron transfer from the maternal to the fœtal organism thus seemed to be regulated in a manner not very different from that suggested by Granick[2] for the gastro-intestinal absorption of iron. Since Nissim[3] first introduced saccharated colloidal iron for parenteral use, several papers on this subject have appeared. Considering the possibility of an untoward effect upon the fœtus brought about by the colloidal iron preparation, it seemed important to investigate this therapeutic agent, particularly as to permeability of the placenta to it, before recommending its use in the anæmias of pregnancy. In doing so, I have used the material and techniques described in my earlier communication[1], in which measured values in normal untreated pregnancy were given; these values have been used as controls in the present investigation.

1 ml. of 'Ferrigen' (in the United States 'Astrafer'), kindly put at my disposal by Astra Ltd., Södertälje, Sweden) was injected intravenously into the pregnant rat 24 hr. before killing; 'Ferrigen' is a ferric carbohydrate of high molecular weight, the stable solution of which contains 20 mgm. of elemental iron/ml., and has a *p*H of 7·3. 51 pregnant rats were used and divided into five groups, pregnancy being allowed to continue for 15, 17, 19, 20 and 21 days. The iron fractions determined were the same as measured earlier[1], that is, for the fœtal bodies: (1) the total iron of the fœtus, and (2) the iron hydrolysable according to the method used (the latter iron fraction was taken to correspond to the depot iron fraction). In the placental organs the hydrolysable iron fraction only was recorded.

It was found that the maternal rats did not reveal any blood dilution 24 hr. after the injection, the hæmatocrit values being within the normal range (41·0 ± 0·9). The plasma iron values of the mother rat were high, the mean value being 265 ± 13·1 γ per cent. As the iron saturation limit for rat serum has been found to be about 500 γ per cent[4], it was concluded that no loosely bound iron was left in the plasma. The values for the hydrolysable iron fraction of the maternal livers was found to be about four times that measured in normal untreated pregnancy, or 48·0 ± 2·9 mgm. per cent. In all the above-mentioned respects, the maternal animals were identical without significant variations associated with the duration of pregnancy. The total and hydrolysable iron concentrations of the fœtal bodies at different stages of pregnancy are shown in Fig. 1. From the fairly high concentrations of total and

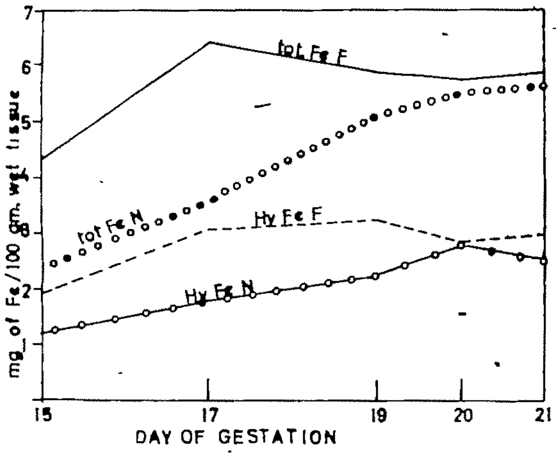

Fig. 1. Total and hydrolysable iron per unit fresh fœtal weight in 'Ferrigen'-treated (*F*) and untreated (*N*) rats during the observed period of pregnancy

hydrolysable iron measured in the fœtal bodies of the rats treated with 'Ferrigen' in the earlier period of gestation, it is clear that some of the iron of the therapeutic agent has passed through the placental barrier. If the preparation had passed freely and unaltered through, we would expect its passage to increase with the duration of pregnancy (see Flexner and Gellhorn[5]). Here, however, the reverse happens. Furthermore, since the iron compound of 'Ferrigen' is very easily hydrolysable, we would expect to find the hydrolysable iron fraction to be proportionally further increased if the preparation had passed the placental barriers unaltered. This did not happen; the hydrolysable iron fraction throughout constitutes some 50 per cent of the total fœtal iron, as was the case in untreated pregnancies. Hence the ferric carbohydrate does not pass through the placental organs unaltered, but is broken down by the maternal organism, giving rise to increased iron depots and serum iron concentration. This is accompanied by an increased synthesis of the intermediate placental iron compound referred to earlier (Fig. 2), from which iron is mobilized by the fœtus according to its need. It is important to note that at no stage of pregnancy do the fœtal bodies of the 'Ferrigen'-treated rats accumulate more iron than is found at term in untreated pregnancies.

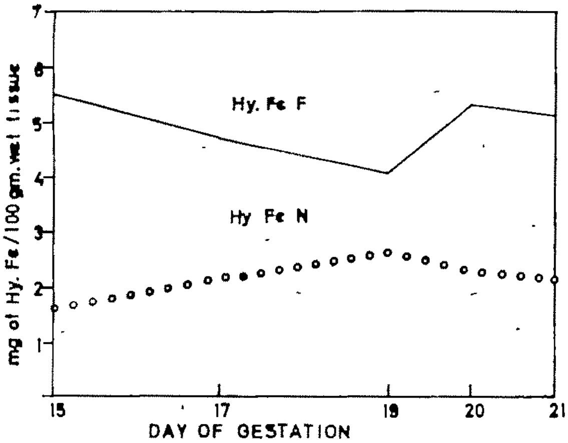

Fig. 2. Hydrolysable iron content per unit fresh weight of the total placental organ during the observed period of 'Ferrigen'-treated (*F*) and untreated (*N*) pregnancies

The features of placental iron transfer suggested here are further supported by the finding that in the 'Ferrigen'-treated rats the period of greatest iron transfer to the fœtus coincides with the lowest iron concentration measured in the placental structures.

A detailed report of these investigations will appear elsewhere.

Effect of Cervical Sympathectomy on the Onset of Œstrus in Ferrets

THE view that the hypothalamus controls the functions of the pars distalis of the pituitary by way of a chemotransmitter transported through the pituitary portal vessels does not accord with the fact that female ferrets, when exposed to added light, will come into heat during the winter months, whether or not there is a direct vascular link between the pituitary and the hypothalamus[1]. Attention has therefore been turned again to the possibility that peripheral nervous pathways may be concerned in the response.

Bilateral superior sympathetic ganglionectomy was performed on sixteen female ferrets during the autumn of 1953. Seven of these animals were exposed to evening illumination (4.30–10.30 p.m. daily) beginning October 30, 1953. The remaining animals were kept under ordinary laboratory conditions. Sham operations were performed on four animals, all of which were exposed to extra light. Fourteen normal female ferrets were housed as control animals with the group of seven operated animals receiving added light, and nineteen normal female ferrets were kept as normal control animals for the nine operated animals in the non-illuminated group.

By January 22, 1954, the eighteen non-ganglionectomized ferrets which were exposed to added light were in full œstrus. At this time no sign of œstrus was apparent in any one of the seven ganglionectomized animals kept in the same room. These animals were still ancœstrous in the middle of June 1954.

Normal spring œstrus had begun by early April in all the nineteen normal control animals kept under ordinary laboratory conditions. At the time of writing, all but two of the nine ganglionectomized animals kept under the same conditions were still ancœstrous.

The results suggest that the cervical sympathetic chains are in some way concerned in the mechanism whereby the exposure of ferrets to light accelerates the onset of œstrus.

Injurious Effect of Air-saturated Water on Certain Invertebrates

It is generally accepted by zoologists as a law of Nature that aquatic animals benefit by as much dissolved air as they can get. Consequently, after a catch is brought home from pond or shore the water is if possible aerated. Yet it is known, especially from the classical work of Juday[1], that whereas the oxygen content of the deep water of certain lakes falls very low and remains so for several months in summer, there is an active invertebrate fauna in and above the mud. It has never been suspected, however, that dissolved oxygen at atmospheric partial pressure, that is, in fully aerated water, might actually be harmful to certain mud dwellers in pond and sea; yet we have found this to be so.

Experiments have now been made in which the survival-time was compared, in water at two different degrees of aeration, of aquatic invertebrates that live in or near the surface of mud. In each experiment, through one sample of water, containing animals, air was bubbled continuously for several weeks, and through another a mixture of one part of oxygen to twenty-four parts of nitrogen, giving water approximately one-fifth aerated. The following animals survived longer in the less well-aerated water: the larvæ of *Chironomus* and of *Anatopynia* (another chironomid midge), *Heterocypris* (an ostracod), young *Tubifex* and young *Scoloplos* (a polychæte worm). The following animals lived equally well in one-fifth aerated and in fully aerated water: *Herpetocypris* (another ostracod), adult *Tubifex*, young *Arenicola*, adult *Planorbis*, *Physa* (another pond snail), *Pisidium* and *Phaenocora* (a rhabdocœle worm). The only animals which survived longer in fully aerated than in poorly aerated water were *Sabella*, young *Planorbis* and young *Limnaea*.

Not only did a number of species survive longer in poorly than in well-aerated water, but *Chironomus* larvæ, young *Tubifex* and young *Scoloplos* grew bigger in the poorly aerated water. In addition, although fewer young *Planorbis* survived in poorly aerated water, nevertheless they grew bigger in it, and *Phaenocora*, which survived equally well in well-aerated and poorly aerated water, grew bigger in the latter.

A full account of this work, in which specific names will be given, is to be published in the *Proceedings of the Royal Society*.

Chlorophyllide, the Probable Precursor of a Growth Inhibitor

When investigating the production of growth substances by *Chlorella vulgaris* var. *viridis*, difficulties were met which were ascribed to a growth-inhibiting substance, possibly Pratt's 'chlorelline'[1]. *Staphylococcus aureus* proved to be a suitable test object for the growth inhibition. Small pieces of filter paper or agar slices containing concentrated and dried crude ether extracts of *Chlorella* were placed on agar plates seeded with bacteria. After 2–5 hr. of diffusion of the extract, and incubation of the bacteria at 37° C., clear inhibition zones were visible around the filter paper or agar slices.

When trying to separate the supposed chlorelline from the growth-promoting substances by shaking ether extracts with dilute hydrochloric acid or sodium bicarbonate, the chlorelline always disappeared from the alkaline as well as from the acid solutions, and also from any remaining ether extract. It was found that light—daylight and red light—inactivated the chlorelline during the working up of the extracts. Green light was inactive, so the manipulations were carried on in dim green light.

Bacillus subtilis proved to react differently from *S. aureus* with chlorelline. In the first place, the inhibition zones were larger than those of *S. aureus*. Secondly, light did not always inactivate the antibiotic action, and thirdly, after the plates had been developed, the inhibition zones expanded during several days in diffuse daylight.

This suggested that chlorelline consists of more than one component. The spectral activity indicating some relation with the chlorophylls, a mixture of benzene, petroleum ether and acetone (10 : 2·5 : 2), was used as a solvent for the separation of the components by paper chromatography. The ether extract was spotted on a paper strip (Whatman No. 4, buffered at pH 6, stored above sulphuric acid) and the ascending method was used. After drying, the paper strips were tested on agar plates seeded with bacteria. The plates received dim light in the incubator. *S. aureus* showed one zone of inhibition ($R_F = 0$) around the spot of the chlorophyllides on the strip; *B. subtilis* showed three zones of inhibition: (*a*) $R_F = 0$, expanding after development; (*b*) $R_F = 0{\cdot}60$, just below the xanthophyll; (*c*) $R_F = 0{\cdot}95$ at the same spot as the carotene.

Being mainly interested in the zone with $R_F = 0$, because of its expansion, we stopped the investigation of the two other inhibitors, which are only active on *B. subtilis*, for the time being.

We first examined the later expansion of the inhibition zone with *B. subtilis*, and found that this is due to the fact that *B. subtilis* can contract in spore form; *S. aureus* cannot do this.

When testing whether light is responsible for the expansion on the *B. subtilis* plates, we obtained varied results. Plates of *B. subtilis* and of *S. aureus* supplied with dried ether extracts on filter paper were incubated immediately in the light (daylight and red light) and in the dark (green light) respectively. In the dark no inhibition was found whatsoever and in the light scarcely any.

After testing several possible explanations with negative results, we came to the next hypothesis, namely, that there is a precursor of the inhibitor proper which is soluble in ether and in water. This precursor would diffuse into the agar plates and be transformed by radiation into an inhibitor which cannot diffuse. Experiment proved that this explanation is the correct one.

The extract was allowed to diffuse from the filter paper into water. The solution formed was tested by means of the cup test on plates with *B. subtilis*. All manipulations were carried out in green light. After incubation in the dark, no zones were present; but after a few hours exposure to daylight clear zones appeared. Controls, remaining in the dark, continued to show no inhibition. Also with *S. aureus* the inhibitor could be demonstrated, provided that the plates were illuminated only after the diffusion of the precursor had taken place. The zones produced in our early experiments evidently were due to the admission of light, which we had not yet learned to avoid properly, after a certain diffusion time in the dark.

We consider these experiments as a proof that the inactive precursor is soluble in water and in ether and is converted by (red) light into the inhibitor, which is either insoluble in water or strongly adsorbed to the carrier (paper or agar).

The evidence that chlorophyllide is the precursor of the inhibitor is corroborated by four further observations: (1) extracts of *Chlorella* cells, grass and kale all show the same inhibition phenomena; when chromatographed, the precursor had always the same R_F value as the chlorophyllide, which is formed during the extraction while the extract is in contact with the extracted cells, that is, in the presence of chlorophyllase; (2) the inhibitor always appears exactly on the same spot as the chlorophyllides, when chromatographed with water, ether, acetone, ethylacetate, a mixture of benzene, petroleum ether and acetone, butanol–water, butanol–water–ammonia, butanol–water–acetic acid, *iso*propanol–water–acetic acid, *iso*butanol–water; (3) the inhibitor is produced only from extracts kept in contact with the cells or tissue and which contain chlorophyllide; we were unable to find it in fresh extracts, extracts from boiled tissue and extracts kept apart from the cells or tissue, all of them containing chlorophyll-*a* and -*b*, but no, or scarcely any, chlorophyllide; (4) when the inhibition has become apparent after illumination, the chlorophyllide has bleached.

A detailed account of the experiments will be published elsewhere.

Investigations are in progress on the interaction of chlorophyllide and light on the cell division of *Chlorella* and of other green plants, especially in view of the many phenomena controlled by light, particularly by the longer wave-lengths, probably through inhibition of cell division (photoperiodicity, leaf abscission, dormancy of seeds, etiolation, etc.).

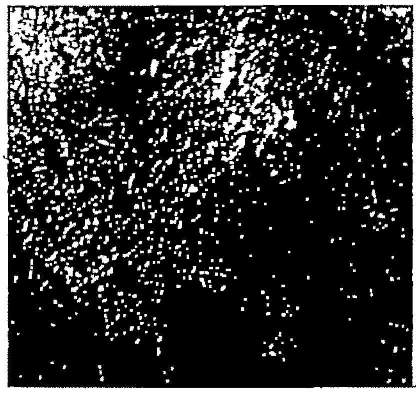
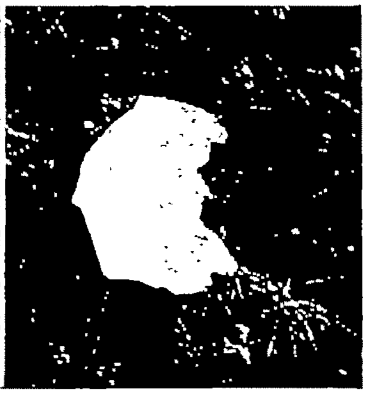
Rapid Extraction of Intact Crystalline Inclusions from the Cells of Plants Infected with Tobacco Mosaic Virus

The intracellular inclusions produced by different plant viruses vary in their stability and resistance to handling. In 1950, I extracted[1] intact inclusions formed by the viruses of cabbage black ringspot, cauliflower mosaic, severe etch, *Hyoscyamus* mosaic and tomato aucuba mosaic. All these inclusions are resistant to handling and are only slightly soluble in distilled water. On the other hand, the inclusions formed by tobacco mosaic virus, as shown by Sheffield[2], are very soluble in water and extremely fragile. In 1953, Steere and Williams[3] devised a freeze-drying technique which enabled these intracellular inclusions to be removed from the cell intact and photographed in the electron microscope.





Since the effect of freeze-drying is probably only a fixation of the nucleoproteins, a much more simple and rapid method has been devised. This consists in removing strips of epidermis, containing crystalline inclusions, from the leaves of mosaic-infected tobacco plants, and immersing them for 3–4 min. in Carnoy's fluid. They should then be rinsed in 96 per cent alcohol and placed in distilled water. The intact crystals can then easily be removed by means of two fine needles, and mounted for electron microscopy. If necessary, the inclusions can be preserved in 96 per cent alcohol for a year or more.

Figs. 1 and 2 are electron micrographs of two crystalline inclusions of tobacco mosaic virus obtained by this method. They show clearly the arrangement of the virus particles.

Acknowledgments are due to Mr. J. D. Bakker for taking the electron micrographs and to Prof. Van Slogteren, director of the Laboratorium voor Bloembollenonderzoek, Lisse, Holland, where this work was carried out.

A New Type of Branching in Liverworts

Recently, we began a study of the morphogenetic effect of various factors on the gemmæ of *Marchantia polymorpha* and *Lunularia cruciata*. These structures offer excellent material for such studies, since they are readily obtainable in quantity at all seasons of the year, are large enough to be handled readily, but small enough to be economical of space and require no special equipment for their study beyond some Petri dishes and a dissecting microscope. We have found that they are sensitive to treatments of many kinds; but for some reason they seem to have been overlooked, for we have been able to find only one paper on experimentation with them—that of Nagai[1], who plasmolysed them with rather interesting results.

At the very beginning of our studies, we found that gemmæ treated in a number of different ways responded by branching in a most unusual manner. Ordinarily, thalli of *Marchantia*, *Lunularia* and other thallus liverworts spread out in a fan-like shape and become continually wider by the extension of thallus tips and the formation of new apical cells from time to time. The new type of branching took place at right angles to the usual direction of branching. This resulted in the formation of two lobes at the tip of the thallus, with one above the other so as to produce a 'double-decker' effect.

Gemmæ which had been treated with various concentrations of a number of substances were grown on a klinostat; it was found that the direction of branching had no relation to the direction of the pull of gravitation, but always took place in a plane parallel to that of the flat surface of the thallus, regardless of the orientation of that structure.

The peculiar type of branching has been produced by all the following substances: acenaphthene, actidione, caffeine, colchicine, chromic acid, naphthalene, parathion, picric acid and sodium cacodylate.

The preceding represents a most diverse and miscellaneous group of chemicals, which have little in common save that five of them are known polyploidizing agents. Thus far, of chemicals tested, surprisingly few have failed to induce the new type of branching. Plant growth hormones—indole acetic acid, indole butyric acid, maleic hydrazide, diphenylamino, ether, benzoguanimine, and dichlorophenoxyacetic acid (2-4-D) have not produced branching.

Irradiation with ultra-violet light produces the new type of branching, and cobalt irradiation has a like effect.

Branching of this type appears to be transitory. Usually, the lower lobe of a pair secures dominance over the upper and grows out rapidly, leaving the upper lobe as a mere ridge or at most a ligule-like appendage. Very rarely, the upper lobe becomes the dominant one and the lower one is then suppressed. In gemmæ grown on the klinostat, both upper and lower lobes may grow for two or three weeks. However, after that length of time, and while still on the klinostat, the lower lobe usually becomes dominant, and the two, formerly independent, lobes grow together in some way not yet understood.

In spite of the results secured with several substances which are known often to cause polyploidy, it is not thought that this branching is due to polyploidy, nor does it appear that any of these effects are permanent. Chromosome counts will be made to find out whether or not polyploidy plays a part in the process. It is proposed also to make studies on the mechanism of this type of branching.

It is notable that branching of this type has never been reported in Nature and has never been found in any growths of *Lunularia* and *Marchantia* observed by either of us in greenhouses or in the open. It has, however, appeared two or three times in control cultures of *Lunularia* grown on filter paper in Petri dishes. A somewhat similar type of bifurcation has been produced by Labouriau[2], by the application of growth hormones to the leaves of the fern, *Anemia collina raddi*.

Details of studies on the new type of branching and of other morphogenetic effects of various factors on liverwort gemmæ will be published elsewhere.

Amino-Acid Content of Plants

WITH the object of correlating existing information and the possibility of establishing a relationship with taxonomy, we have examined, both qualitatively and quantitatively, the free and combined amino-acid content of the cell juices of a number of plants widely distributed throughout the vegetable kingdom, using a carefully worked-out paper chromatographic method. A complete account of the work will be published in due course; but in view of recent publications[1] on the use of paper chromatography in the study of various aspects of the distribution and metabolism of amino-acids in plants, it appears to be desirable to place on record the results we have obtained during the past few years.

Table 1 gives the percentages of the total (Kjeldahl) nitrogen present in that portion of the total solids of the plant juice soluble in 75 per cent ethyl-alcohol as each of the amino-acids listed, and Table 2 the corresponding figures for the amino-acids found in hydrolysates of the insoluble residues after alcohol extraction. The amino-acids found in *Malus sylvestris* agree with those qualitatively identified by Hulme and Arthington[2]. *Funaria hygrometrica*, *Mucor mucedo*,

Pinus sylvestris and *Equisetum arvense* were chosen as well-known examples of the Bryophyta, Thallophyta, Gymnospermae and Pteridophyta respectively. We have also obtained qualitative results on *Lolium italicum* which agree closely with those of Synge[3] on *L. perenne*, and on *Medico sativa* agreeing with those of Vickerey[4], who used standard chemical methods of analysis.

E. arvense has also been examined at regular intervals throughout the development of the sporophyte generation.

Work on these and related lines is being actively pursued.

Occurrence of *Falkenbergia rufolanosa* in the Isle of Man

Since the reports by de Valera[1], Harvey and Drew[2], and Drew[3] of the occurrence of *Asparagopsis armata* Harv. and what is believed to be another phase of its life-history, *Falkenbergia rufolanosa* in a number of localities in Ireland and on the south-west coast of England, its spread around the British coast has been watched with interest by phycologists. A spread eastwards along the south coast was reported by Kerslake[4] in September 1953 when *Asparagopsis armata* was found on Wembury Beach.

During the course of a survey of an area in and around the harbour at Port St. Mary, Isle of Man, by a party of students from the University of Liverpool and Royal Holloway College, London, at the end of March, *Falkenbergia rufolanosa* was found in great quantity floating in the water in the harbour at low tide, and both floating and attached to other seaweeds in pools in various positions on the shore. This is the first record for the plant in the Isle of Man, and it is of interest that it should appear in abundance, first of all, in one of the functioning harbours and one used by coastal vessels. A search of the shores near by indicated that it had, as yet, spread very little from the harbour, though the spread had obviously begun; it was found growing attached in a few pools on the outer side of the breakwater, and one can perhaps assume that its spread around the Island is only a matter of time. Of all the material examined, none was found to be reproducing.

It will be of interest to see whether the invasion of the Isle of Man by *Falkenbergia* is followed, as it has been in other places, by *Asparagopsis armata*.

Use of Glutamine by the Mammary Gland for the Synthesis of Casein

In continuation of earlier work on casein synthesis[1], further experiments have aimed at determining which components, taken from the blood-stream by the mammary gland, provide the glutamic acid of casein.

1-^{14}C DL-glutamine was injected intravenously into a lactating goat and specific activities were measured in various components of blood and milk taken at intervals up to 12 hr. after injection. During the first few hours the specific activity of the free glutamine of plasma remained many times that of both the free glutamic acid and the glutamic acid of plasma proteins. This difference is illustrated (Table 1) by the specific activities in blood taken at 3 hr. after injection; in samples taken at 20 min. and 1 hr. the specific activities of glutamine were higher than at 3 hr. while those of free glutamic acid and plasma protein glutamic acid were approximately the same or lower.

Table 1. SPECIFIC ACTIVITIES IN BLOOD AND MILK SAMPLES TAKEN AT 3 HR. AFTER INJECTING 1-^{14}C DL-GLUTAMINE (425 MGM. : 38·0 μC.) (μc./m.mol. carbon in carbon No. 1)

Blood plasma		Milk	
Free glutamine	117×10^{-6}	Casein glutamine (*a*)	143×10^{-6}
Free glutamic acid	$27{\cdot}2 \times 10^{-6}$	Casein glutamic acid (*a*)	$< 25 \times 10^{-6}$
Plasma protein glutamic acid	$1{\cdot}73 \times 10^{-6}$	Total glutamic acid of casein (*b*)	122×10^{-6}

(*a*) After enzymatic hydrolysis (*b*) After acid hydrolysis.

Casein samples were hydrolysed in two ways: by heating with hydrochloric acid and by incubating with a pancreas suspension. The specific activity of glutamic acid in each acid hydrolysate was measured, and glutamine and glutamic acid were isolated from each pancreas hydrolysate and their specific activities also measured. The first milk sample was taken at 1·5 hr.; the specific activities found in the casein of the second milk sample taken at 3 hr. are shown in Table 1. It is seen that the specific activity of casein glutamine is slightly higher than that of the free glutamine of plasma at 3 hr., while that of casein glutamic acid is much lower. The results suggest that those residues which are present in casein as glutamine are derived largely from the free glutamine of plasma, and those present as glutamic acid are derived from some other source.

To confirm that the free glutamine of plasma is directly incorporated into casein, (1-^{14}C : amide-^{15}N) DL-glutamine was injected intravenously into the goat and milk taken at 1·5 hr. after injection. It is seen in Table 2 that, as expected, the ratio (μc/m.mol. carbon : atoms per cent excess ^{15}N) in the glutamine

Table 2. (1-^{14}C : AMIDE-^{15}N) DL-GLUTAMINE (563 MGM.) INJECTED AND MILK TAKEN 1·5 HR. LATER

	Atoms % excess ^{15}N	μc./m.mol. carbon in carbon No. 1	$\dfrac{\text{μc./m.mol. carbon}}{\text{Atoms \% excess }^{15}\text{N}}$
Injected glutamine	25·8	$1{,}800 \times 10^{-6}$	$69{\cdot}8 \times 10^{-6}$
Casein glutamine	0·611	$30{\cdot}6 \times 10^{-6}$	$50{\cdot}1 \times 10^{-6}$
Amide N. of casein (*a*)	0·444	—	—
Non-amide N of casein (*b*)	0·004	—	—

(*a*) Nitrogen released as ammonia on acid hydrolysis. (*b*) Nitrogen not released as ammonia on acid hydrolysis.

of casein was approximately the same as in the injected glutamine.

It has been postulated that γ-glutamyl peptides formed from glutamine by enzymatic exchange reactions are important intermediates in protein synthesis[2]. The present results suggest that the glutamine which is incorporated into casein does not exchange or lose its amide nitrogen in the process, and therefore apparently does not pass through intermediate γ-glutamyl peptides.

Techniques which differed from those used in previous work on casein synthesis[1] were as follows. 1-^{14}C DL-glutamine was synthesized from 1-^{14}C DL-glutamic acid by the method of King and Kidd[3]; amide-^{15}N DL-glutamine was synthesized from DL-glutamic acid and ^{15}N ammonia by a slight modification of the same method. The pancreas suspension contained 25 gm. of fat-free and minced pig pancreas/100 ml. 25 per cent ethanol; before use it was incubated and then dialysed to remove amino-acids. Glutamine and glutamic acid were isolated from blood plasma, and protein hydrolysates, by chromatography on 'Dowex-50' resin. Specific activities of carbon No. 1 of glutamine and glutamic acid were measured after decarboxylation with glutamic decarboxylase. The amide nitrogen was obtained from glutamine for ^{15}N analysis by converting to pyrrolidone carboxylic acid and ammonia.

I am indebted to Dr. D. D. Woods for providing the glutamic decarboxylase and pancreas suspension, and to Dr. D. H. Tomlin for making the determinations of nitrogen-15.

A Case of *Shigella sonnei* Septicæmia in a Calf

During the course of routine laboratory examinations performed on a long bone from a two months-old calf, which died without symptoms the previous day, we isolated in pure culture from the bone-marrow a strain of a Gram-negative, non-motile, non-spore-forming organism.

At the time of the isolation, it exhibited the following characteristics:

Glucose	acidified without gas in 24 hr
Lactose	acidified without gas in ten days
Saccharose	acidified without gas in eight days
Mannitol	acidified without gas in 24 hr.
Rhamnose	acidified without gas in four days
Salicin	no fermentation recorded in thirty days
Xylose	no fermentation recorded in thirty days
Methyl red reaction	positive
Voges–Proskauer reaction	negative
Indole	no production recorded
Hydrogen sulphide	no production recorded
Urease	no production recorded
Sodium citrate	no growth recorded
IMVIC formula is thus	– + – –

As these were the characters of *Shigella sonnei*, the agglutination with an antiserum was performed and confirmed the identification.

This is the first case, so far as we know, of a human *Shigella* occurring in an animal, either as an intestinal infection or as a septicæmia. The finding of *Sh. sonnei* in the medulla is not extraordinary, since it has already been described in human beings[1]. The importance of our finding is still to be assessed, especially for its repercussion in meat hygiene.

We are indebted to Dr. R. Buttiaux for confirmation of our diagnosis. Full details of our investigations will be published elsewhere.

Identification of Certain 'Ketosteroids' from Cattle Urine as Ionone Derivatives

In recent years, our knowledge of 17-ketosteroid excretion and metabolism in the human being has greatly increased. However, in the little research work in this field which has been devoted to cattle, great uncertainty has always prevailed regarding the nature of the compounds measured by the Zimmermann or Pincus reaction. All investigators are agreed that the steroids from cattle urine could in no case be identical with the 17-ketosteroids from human urine[1].

A short time ago we succeeded in identifying several of these compounds as ionone derivatives, which Prelog and his co-workers isolated from pregnant mares' urine[2]. The presence in cattle urine of these substances had been surmised by Klyne (personal communication). One of the two main fractions, which we obtained by chromatography of the neutral ketonic lipid fraction from cattle urine, without regard as to whether it was urine from bull, cow or ox, proved to contain (2,3,6-trimethyl-benzal)-acetone (Prelog's ketone *J*) among other, as yet unidentified, compounds. The other main fraction consisted almost entirely of 5-hydroxy-*cis*-tetrahydro-ionone (Prelog's hydroxyketone *G*) and a smaller fraction, which follows the second main fraction, consisted of this compound and 5-oxo-*cis*-tetrahydro-ionol (Prelog's hydroxyketone *E*). The presence in cattle urine of other ionone derivatives which have been isolated from mares' urine, such as 5-oxo-*cis*-tetrahydro-ionone (Prelog's diketone *D*), 2,2,8-trimethyl-bicyclo-[0,0,4]-dekadien-5,7-one-4 (Prelog's ketone *K*) and a bicyclic hydroxyketone of not fully established structure (Prelog's hydroxyketone *C*), is not excluded, but as yet not definitely proved.

It is very remarkable that all these substances react in the Zimmermann test. The absorption spectra of several of the coloured compounds are identical with those of cattle urine extract: an absorption curve which falls continuously from shorter to longer wave-lengths with a more or less pronounced plateau at about 500 mμ. One of the compounds (ketone *J*) even gives a pure violet Zimmermann colour which is similar to that of 17-ketosteroids. It shows a distinct absorption maximum at 530 mμ and low absorption at shorter wave-lengths.

With the Pincus reagent the hydroxyketone *G* gives a blue-violet colour with an absorption maximum at 550 mμ, identical with the colour given by the second main fraction from cattle urine extract. In some cases this absorption maximum appears in the Pincus colour of the total ketonic fraction. This maximum has also been described previously by Meschaks and by Mixner and Saunders.

Among these ionone derivatives, which form by far the greater part of the compounds determined by the usual ketosteroid reactions, a few 17-ketosteroids occurred in minute quantities. Three of these could be identified with more or less certainty as dehydro-*epi*-androsterone, etiocholanolone and 11-hydroxyandrosterone. In any event, the large amounts of the testosterone metabolites androsterone and etiocholanolone, which are excreted in human urine, were shown to be absent in cattle urine. This is most peculiar, as testosterone is believed to occur in the cattle organism. It was isolated for the first time from bulls' testes by Laqueur in 1935. These findings, however, are in accordance with the very low content of androgens in bulls' urine.

As to the origin of these ionone compounds, it is very likely that they are derived from carotenoids (Prelog *et al.*). Bearing in mind the fact that the ionone derivative 5-hydroxy-*cis*-tetrahydro-ionol, which Prelog and his co-workers isolated from pregnant mares' urine (diol *A*), has also been found in bulls' and pregnant cows' urine by Broadbent, Brooks and Klyne[3], and that horses and cattle mainly feed on the same carotene-rich material, it is not surprising that the same carotenoid derivatives should occur in the urine of both kinds of animals. It seems very probable, therefore, that these compounds will occur also in the urine of other animals whose food is rich in carotenoids, and that they will interfere there with ketosteroid determinations. We found in a preliminary investigation that they are absent from dogs' urine.

Full details of this work, which is still in progress, will be published elsewhere.

We are much obliged to Prof. V. Prelog and his co-workers, Dr. B. G. Engel and Dr. J. Würsch (Zurich), who supplied us with samples of the ionone compounds for identification purposes. Thanks are also due to Dr. W. Klyne (London) for valuable information.

This work is financed by the Agricultural Research Council T.N.O. and thanks are due to Prof. L. Seekles for laboratory facilities and his interest in the investigation.

Effect of Œstrogen and of Vitamin A on Vaginal Cornification in Tissue Culture

RECENT interest in the rodent vaginal epithelium as a target organ for studying the interaction of dietary and endocrine factors[1] has led to an investigation of the post-fœtal vaginal epithelium of the rat in tissue culture. Whereas Emmens and Ludford[2] were unsuccessful in a similar attempt, quite recently Hardy, Biggers and Claringbold[3] were able to culture the mouse vaginal epithelium by the hanging-drop method and demonstrated the sensitivity of this tissue to œstrogenic substances.

In the present investigation, 99 explants of the vaginal epithelium of eleven prepuberal rats (3–4 weeks old) have been successfully grown for one to nine days in watch glass cultures[4,5], and keratinization has been produced precociously by means of œstrone (0·13 mgm./100 ml. media) added to the nutritive medium. It was found, however, that the control vaginal epithelium cultivated in a standard medium also underwent keratinization, although not as rapidly as that treated with the folliculoid.

Before cultivation the vaginal epithelium is in the typical prepuberal state. After only one or two days on the œstrogenized culture medium, the epithelium becomes stratified, squamous and highly keratinized, although not hyperplastic. Up to the second day, the control groups appear much like the tissue before cultivation; but during the third or fourth day the cells beneath the original cuboidal epithelium become squamous, and by the fourth or fifth day have formed a typical stratified squamous epithelium and keratin. On continued cultivation, the epithelium becomes highly cornified and is histologically indistinguishable from that treated with œstrone. Careful examination of the control photograph presented by Hardy *et al.*[3] shows the beginning of a stratified squamous epithelium beneath the superficial cuboidal cells in their 96-hr. culture of mouse vagina; in our experiments with rat tissue the cuboidal cells are afterwards sloughed.

These results confirm the observations of Hardy *et al.*[3] that œstrogens have a direct action on the rodent vaginal epithelium *in vitro*, but the local response to a steroid under the simplified conditions of organ culture may not be evoked in the same way as a systemically distributed steroid *in vivo*. These *in vitro* results, therefore, do not exclude the possibility of metabolic 'activation' as suggested by Szego and Roberts[6].

The tendency for the control groups to undergo keratinization may be due to a lack of available vitamin A. Recent experiments have shown that synthetic vitamin A added to the control culture medium not only suppresses keratinization but also induces the production of a mucus-secreting epithelium (cf. Fell and Mellanby's observations[5] on chick ectoderm *in vitro*). On the other hand, a concentration of vitamin A which inhibits keratinization in normal medium does not prevent but only delays cornification in the presence of œstrogen. A detailed report of this work will be published in the near future.

Local Anæsthetic Potency and Penetration of Monomolecular Layers of Nerve Lipoids

IN an attempt to find the site of action of local anæsthetics in peripheral nerves, we have endeavoured to discover whether a correlation exists between the anæsthetic potency of some local anæsthetics and their penetration of a monomolecular layer of nerve lipoids.

Table 1. MINIMUM ANÆSTHETIC CONCENTRATION, INCREASE IN PRESSURE IN THE MONOLAYER, AND NUMBER OF MOLECULES PENETRATIN THE MONOLAYER, pH 7·0

In columns 3, 5 and 7, procaine is set equal to 1

Anæsthetic	Minimum anæsthetic concentration (mM/L.)	Relative anæsthetic potency	Increase in pressure in monolayer (dyne/cm.)	Relative increase in pressure	Concentration in monolayer (mol./cm.^{2} × 10^{13})	Relative concentration
Procaine	4·6	1	7·0	1	8·9	1
Cocaine	2·6	1·8	9·0	1·3	10·0	1·1
Tropacocaine	2·2	2·1	9·4	1·3	9·7	1·1
Tetracaine	0·01	460	2·5	0·4	3·8	0·4
Nupercaine	0·005	920	3·7	0·5	5·4	0·6
Butyl alcohol	68	0·07	9·8	1·4	14·7	1·7

The anæsthetic potency was estimated as the minimum anæsthetic concentration, that is, the minimum concentration which produces anæsthesia when distribution equilibrium of the anæsthetic agent between its solution and the nerve tissue has been attained. It was determined on isolated desheathed sciatic nerves from frogs (*Rana esculenta*). The local anæsthetics investigated are all tertiary amines which in aqueous solutions will be partly dissociated. The anæsthetic potency of these local anæsthetics depends on the pH of the anæsthetic solution; it was determined at pH 7·0. Butyl alcohol was taken as a representative of an undissociated aliphatic anæsthetic.

The nerve lipoids used for the monolayer were extracted from frogs' sciatic nerves. The monolayer was spread on a Ringer solution which contained 0·01 M sodium phosphate, pH 7·0, and the area of the monolayer was adjusted to a pressure of 10 dynes/cm. This area was kept constant during the experiment. Varying concentrations of the local anæsthetics were injected in the Ringer solution below the monolayer, and after careful stirring, the increase in pressure against the Ringer solution was measure (Fig. 1).

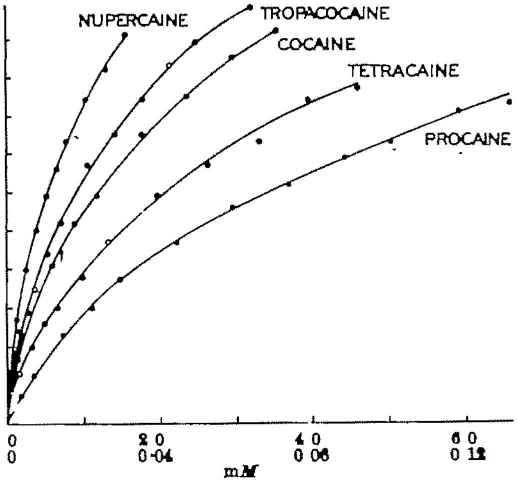

Fig. 1. Increase in pressure in a monolayer of nerve lipoids plotted against the concentration of the local anæsthetics in the Ringer phosphate buffer, pH 7·0. The upper row on the abscissa refers to procaine, cocaine and tropacocaine the lower to tetracaine and nupercaine

Table 1 shows the increase in pressure produce by the minimum anæsthetic concentration of the fiv local anæsthetics and of butyl alcohol. In additio is shown the number of molecules which penetrat per cm.^{2} of the monolayer at the minimum anæsthet concentration. These numbers were calculated b means of Gibbs's adsorption equation.

The order of the ability of the six anæsthetics tc penetrate the monolayer followed that of thei anæsthetic potencies; but the increase in pressure ir the monolayer produced by the minimum anæsthetic concentration of the six anæsthetics differed (Table 1, col. 4), and the numbers of molecules penetrating per cm.^{2} were also different (col. 6). However, ir view of the large differences between the minimum anæsthetic concentrations (1 : 920, or if butyl alcohol is included, 1 : 13,500), the differences in the results from the monolayer are so small that there seems to be a correlation between the anæsthetic potency and the penetration of a monolayer of nerve lipoids.

A more detailed report of this work will appear in *Acta Pharmacologica et Toxicologica*.

Heparin and Histamine in Mast-Cell Tumours from Dogs

THE granular basophil cell of the tissues, the mast cell, has for long been thought to be the source of heparin[1]. Recently, it has been shown that the mast cell is also rich in histamine, a suggestion first made on histological grounds[2] and afterwards confirmed by the finding of a strong positive correlation for mast cells and histamine in a wide variety of normal and pathological tissues[3]. However, up to the present, the only comparative study of mast cells for heparin and histamine in the *same* starting material has been carried out on normal ox lung, in which the pleura especially yielded high values for all three[4]. It is thus of some interest that we have recently obtained six cases of subcutaneous mast cell tumour from dogs for estimation of their heparin and histamine contents.

As described elsewhere[5], tissue for histamine estimation was immersed as quickly as possible after removal in 10 per cent (v/v) trichloracetic acid for later extraction and assay on the standard guinea pig

Table 1. HISTAMINE AND HEPARIN VALUES OF SIX CASES OF SUBCUTANEOUS MAST CELL TUMOUR FROM DOGS

Case No.	Breed	Age (yr.)	Sex	Site	Delay (hr.)	Duration (months)	Histamine (μgm./gm.)	Heparin (I.U./gm.)
I	Terrier	10	M	Flank	12	1·5	765	61·2
II	Terrier	7	M	Perianal	0	6	500	147·2
				(recurrence)	0	2	790	54·2
III	Golden cocker spaniel	10	F	Flank	0	2	1,290	110·0
				(recurrence)	3	2	650	357·0
IV	Golden Labrador	10	F	Leg	50	Unknown	7	120·0
V	Scottie	7	F	Leg	3	3	520	21·4
				(recurrence)	0	2	277	21·0
VI	Black Labrador	12	M	Thigh	48	24	550	174·0

Ileum preparation or on the blood pressure of the atropinized cat, the specificity of the response in each case being confirmed by the use of mepyramine. Tissue for heparin estimation was placed at the same ime in water containing a few drops of chloroform ind was later digested with trypsin at *p*H 8 and assayed for anticoagulant activity by the method of Adams and Smith[5]. The results are presented in he accompanying tables. Table 1 lists the breed, age and sex of the dog and the site of its tumour. Of importance for the interpretation of the histamine values is the delay (shown in the sixth column) which elapsed between removal of the tumour and its preservation in trichloracetic acid. Attention has previously been directed to the progressive loss of histamine in small fragments of excised tissue exposed o air or immersed in water[3]. Table 2 gives average control values for histamine and heparin in a series of non-malignant tissues taken from normal or tumour-bearing dogs and placed at once in trichloracetic acid or chloroform water.

Table 2. AVERAGE CONTROL VALUES FOR HISTAMINE AND HEPARIN IN NON-MALIGNANT TISSUES FROM DOGS

Tissue	Histamine (μgm./gm.)	Heparin (I.U./gm.)
Kidney	1	6·2
Lymph node	4	9·0
Spleen	5	7·2
Skin	9	11·0
Lung	25	12·8
Liver	25	19·7

It is necessary merely to glance at the tables to see that mastocytomas from dogs are in general exceedingly rich in both heparin and histamine, the low histamine value in case IV being no doubt due in part to the delay which occurred before this small specimen was treated with trichloracetic acid and in part to its having been sent to us wrapped merely in a swab moistened with formalin. A similar delay occurred with specimen VI: however, this was an exceptionally large tumour and only its comparatively fresh central portion was used for histamine assay 48 hr. later. The heparin values also showed considerable variation, and here it is of interest to observe that the tumours with the highest heparin contents were also those which contained the highest proportion of mast cells filled with strongly metachromatic granules. Indeed, when distant metastases were present, we found it possible to anticipate histological evidence of tumour mast cells in other organs by the demonstration of their raised histamine and heparin values.

Thus, so far as conditions in the dog are concerned, it is clear that not one but at least two highly potent pharmacological substances are present in the tissue mast cells—heparin and histamine.

Full details of these tumours will be published elsewhere.

Photographs of Serial Sections of the Lung projected rapidly in Sequence using 16-mm. Film

THE course and condition of small branching structures within a sample block of histological material cannot be appreciated with ease or demonstrated very successfully. With lung tissue, for example, casts and coloured, or radio-opaque, injections of the bronchial and vascular trees have been of great assistance; but these methods usually entail the removal or clearing of surrounding structures. Alternatively, serial sections may be observed *en masse* by serial reconstructions, thus overcoming, to some extent, the fact that the direct examination of serial sections in sequence is too slow for a full understanding of the plan of the tissue as a whole.

This communication describes a method for the visualization of a whole block of tissue histologically by introducing a regular short time interval between visual impressions of consecutive serial sections photographed on 16-mm. film. Preliminary trials with serial sections of rabbits' lungs have proved interesting.

There are two principal problems, the first being the inevitable loss of detail from the use of small frames of film. This disadvantage will vary with the type of material and the power of magnification, but in the present trials it has not been severe enough to detract from the interpretation of the projected film. The use of 35-mm. film would improve the quality of the picture, but exceptionally fine detail is not necessary when differing histological appearances are presented in rapid succession.

The second problem is to match one section accurately to the next, and I have been fortunate in obtaining the use of a hand-operated Kodak ciné camera fitted with a sliding prism, which deflects the image to be photographed upon a ground-glass screen. The image of this screen was enlarged and projected on paper, giving a picture 9 cm. × 12 cm. The principal features of the image were drawn in pencil and erased after each change of field, and the intensity of the light was adjusted to give an exposure time of 5 sec. The open positions of the revolving shutter were marked against the positions of the crank for reference with each exposure. Test strips of negative film were developed in the laboratory and the final spliced strips were printed elsewhere.

Before film was used, a trial was made with a short series of consecutive sections photographed on 9 cm. × 12 cm. plates and matched by ink sketches on the ground-glass screen. Prints were mounted on cards and it was found that four changes of section each second could be followed satisfactorily. This rate was used in the film, four frames being exposed for each tissue section (film speed, 16 frames/sec.).

The film sequence could not be presented in motion from the start. The projection of the first of the serial sections was maintained for about five seconds to allow for the choice of a particular structure to be followed in the sequence. It was found necessary also to project the last section for the same length of time. Smoother sequence would be obtained using very thin serial sections, but vessels in the lung are easily disturbed when cut and a thickness of 7 μ (melting point of wax, 58° C.) was needed to avoid most of this displacement. Lung tissue tends to become stretched and distorted when cut and mounted in paraffin wax. This was not obvious until the film was projected, when these defects were seen to interfere, to some extent, with the smooth sequence of section detail. The use of a firmer embedding medium may solve this problem. A whole sequence was spliced in ring form and could be repeated until all the features of the film had been assimilated. One sequence was prepared from sixty transverse sections (7 μ thick) along the course of a branch of a lower lobe bronchus in the undistended lung of a rabbit, and it was possible to trace the lumen of a small bronchus through several branches down to the related air sacs in 15 sec. The mode of branching of pulmonary arteries and their relations to branching bronchi were well shown, as also was the distribution of collections of lymphoid tissue.

The further application of this method to the study of lungs and other organs, normal or abnormal, should assist both in the evaluation of serial section material in general and in its presentation for teaching purposes.

I wish to thank Prof. Geoffrey Hadfield for his advice.

Radio Emission from the Andromeda Nebula

Observations have been made at a wave-lengt of 3·7 m. with interferometers of different resolvin powers to determine the distribution of radio brigh ness across the Andromeda nebula, *M*31, which ha also been investigated at radio wave-lengths b Hanbury Brown and Hazard[1]. When observations a made with small movable aerials, errors are cause by reception of radiation from adjacent radio star Good discrimination was therefore obtained wit the present measurements by using several differen sections of the large Cambridge radio telescope although this method reduced the number of differen axes and aerial spacings available. The relationshi of the four axes used to the Andromeda nebula shown in Fig. 1.

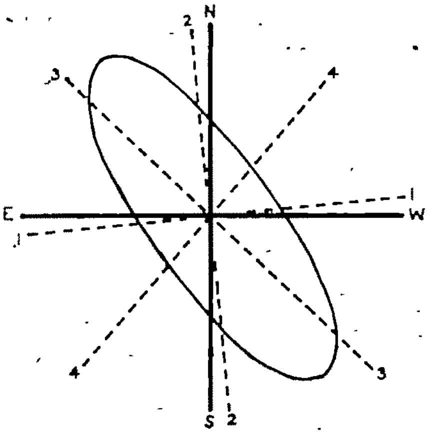

Fig. 1. Relationship of the interferometer axes to the Andromeda nebula

Column 1 of Table 1 gives the recorded amplitud expressed as a fraction of the amplitude for zer spacing, the total intensity of the source, which wa found to be $2 \cdot 0 \times 10^{-24}$ watts.m.$^{-2}$(c./s.)$^{-1}$.

The strip distribution of radio brightness projecte on axis 1 is shown in Fig. 2, together with the stri distribution of the optical emission from *M*31, o the mass as derived by Wyse and Mayall[3] and of th expected distribution of radio brightness calculated using the same model as that derived by Westerhou and Oort[4] from radio measurements on our own galaxy. The recorded amplitudes which would be expected from the models of Wyse and Mayall and Westerhout and Oort are shown in columns 2 and 3 of the table.

From Fig. 2 and from a comparison of the amplitudes for the axes 2 and 3, it can be concluded that the source of radio emission extends to radial distances

Table 1

Axis 1				Axes 2			
Aerial spacing	1	2	3	Aerial spacing	1	2	3
6 λ	0·96±0·1	0·95	0·98	14 λ	0·35±0·15	0·56	0 70
9 λ	0·84±0·1	0 91	0 94	Axis 3			
12 λ	0·60±0·15	0·88	0·89	18 λ	0·22±0·1	0·37	0·54
18 λ	0 20±0 1	0·70	0 80	Axis 4			
				18 λ	0·22±0·1	0·37	0·90

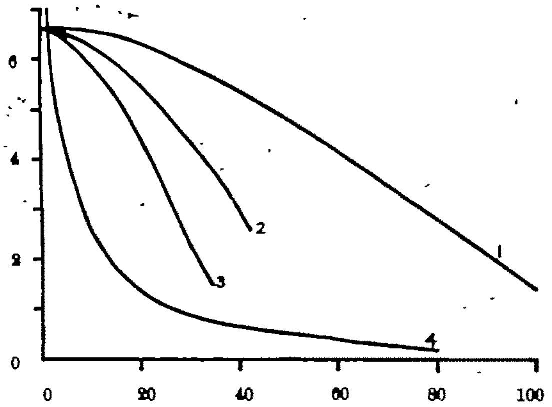

Fig. 2. The strip distributions, projected on axis 1, of: (1) the experimental determination of radio brightness; (2) Wyse and Mayall model; (3) Westerhout and Oort model; (4) the optical emission

the plane of the nebula which are considerably eater than either of the models. Further, examinaon of the figures for axis 4 shows an even greater screpancy between the observed and derived gures; the observations indicate that the radio nission also extends to very great distances normal the plane of the nebula. The existence of uch a distribution of sources is of considerable imortance.

Westerhout and Oort[4] showed that it is only possible explain the observed distribution of radio emission om the galaxy in terms of sources distributed like ommon stars if an isotropic component is subtracted om the observed values. They concluded that this omponent is probably of extragalactic origin, a ossibility which has been discussed further in a paper y Shakeshaft[5]. The present observations suggest at, in fact, most of this component may be ue to the existence of galactic radio sources disributed to great distances from the plane of the alaxy.

In order to make an estimate of the magnitude of is component, and in the absence of more detailed formation, it is convenient to interpret the present bservations in terms of two separate populations f radio sources: (*a*) a distribution similar to that roposed by Westerhout and Oort, which contributes bout a third of the total intensity; (*b*) a distribution hich has approximately spherical symmetry and xtends to radial distances greater than 10,000 parocs and which contributes about two-thirds of the otal intensity. With this model it can be shown at an observer in the plane of *M*31 at a radial istance corresponding to that of the solar system ould find a brightness temperature in the direction f the poles of about 200° K. at a wave-length of ·7 m.

In order to make an estimate of the polar intensity hich might be produced by such a population of ources in our own galaxy, it is convenient to suppose that the compositions of the two galaxies are lentical; the relative intensities in the polar irections will therefore be related to the total power adiated by the two galaxies. Westerhout and Oort howed that the total intensity to be expected from he concentrated population of our own galaxy at e distance of *M*31 would be 2 × 10^{-24} watts.m.$^{-2}$ ./s.)$^{-1}$ at 3·7 m. when corrected for the new distance scale. It has been found that the flux associated with this population in *M*31 is approximately 0·7 × 10^{-24} watts.m.$^{-2}$(c./s.)$^{-1}$. It therefore seems possible that the extended population of radio sources in our own galaxy might produce a polar brightness temperature of about 600° K., a figure which is comparable with the observed value of 950° K.[6].

The observations of the Andromeda nebula have suggested the existence of a hitherto unexpected population of radio sources; a similar population in our own galaxy might also account for a large part of the so-called 'isotropic' component of cosmic radio emission.

This work was carried out as part of a programme of research supported in the Cavendish Laboratory by the Department of Scientific and Industrial Research, to which I am indebted for a maintenance allowance.

Recession of the Galaxies in Eddington's Theory

THE first important formula in Eddington's "Fundamental Theory" (Cambridge, 1946) is (p. 6)

$$R_0/\sqrt{N} = 2\sigma, \qquad (1)$$

where R_0 is the radius of an Einstein universe, N the number of particles and σ the uncertainty constant of the physical origin. Einstein's formula for the total mass, considered as equivalent to $\frac{1}{2}N$ hydrogen atoms each of mass m, gives the independent relation (p. 10):

$$R_0/N = \gamma m/\pi c^2 = 3\cdot 95 \times 10^{-13} \text{ cm.} \qquad (2)$$

From (1) and (2):

$$R_0 = (2\sigma)^2/3\cdot 95 \times 10^{-13}, \qquad (3)$$

and Eddington finds Lemaître's limiting speed of recession of the galaxies, $V_0 = c/(R_0\sqrt{3})$, to be 572 km./sec. per megaparsec. For this "most accurate" determination, he uses in (3) his formula for $1/\sigma$ as a numerical multiple of the Rydberg constant. The 'observed' recession-factor he estimated (1944) to be 560 km./sec. per megaparsec, in agreement with his result.

In reviewing this book, I noted one[1] error, which occurs on p. 5 just before the result (1) above; this implies that in (1) 2σ should be 3σ. Thus the value of R_0 in (3) should be multiplied by 9/4 and V_0 by 4/9; the same change applies to his determination $V_0 =$ 585 based on proton–proton scattering. This change is not in conflict with recent astronomical observation; for Baade has found[2] that current estimates of the distances of the galaxies should be doubled, so that the recession factor should be halved.

Amending equation (1) spoils the good agreement of N with Eddington's purely theoretical value $\frac{3}{2} \times 2^{256} \times 136$; but it does not affect his calculated values of the microscopic physical constants (in Chapters 2, 3, 9 and 11).

Thermodynamics of the Two-Fluid Model of Liquid Helium II

THE two-fluid model for liquid helium II first put forward by the late F. London[1] has been largely accepted as at least a very useful working hypothesis. There are, however, certain thermodynamical difficulties arising from this model which do not seem to have received an entirely satisfactory solution. For example, Gorter[2] has pointed out that an application of the phase rule leads to a unique triple point for the co-existence of the two fluids and the vapour phase, whereas, in fact, a whole range of such points is observed; and he has suggested that this may be explained by assuming that the Gibbs function for the fluids and vapour is not linear in the concentrations.

In this communication an alternative explanation of this anomaly is put forward based on the hypothesis that there is chemical equilibrium between the normal and superfluid components. This hypothesis seems reasonable, if not inevitable, since whatever the exact mechanism of the transition from the normal to the superfluid component, the very fact that such a transition does take place under changes of temperature (and pressure) would seem to imply some sort of chemical equilibrium between the two components for any given state of the liquid. Suppose, then, that U is the internal energy of a mass m of the liquid of volume V and entropy S, and let m_1 and m_2 be the masses of the normal and superfluid components, respectively. If we define the chemical potentials of the two components to be

$$\varphi_1 = \left(\frac{\partial U}{\partial m_1}\right)_{V,S,m_2}, \quad \varphi_2 = \left(\frac{\partial U}{\partial m_2}\right)_{V,S,m_1},$$

then for a general infinitesimal reversible change:

$$dU = -pdV + TdS + \varphi_1 dm_1 + \varphi_2 dm_2. \qquad (1)$$

If u, s, and $1/\rho$ are the specific energy, entropy and volume, respectively, equation (1) may be written:

$$du = (p/\rho^2)d\rho + Tds + \varphi_1 dc_1 + \varphi_2 dc_2, \qquad (2)$$

where

$$c_1 = m_1/m, \quad c_2 = m_2/m.$$

Since

$$c_1 + c_2 \equiv 1,$$

we have:

$$du = (p/\rho^2)dp + Tds + (\varphi_1 - \varphi_2)dc_1. \qquad (3)$$

But the condition for chemical equilibrium between the two components is expressed by $\varphi_1 = \varphi_2$, since mass is conserved in the transition between the two components. Therefore:

$$du = (p/\rho^2)d\rho + Tds;$$

that is, u is a function $u(\rho_1 s)$ of ρ and s only. B
$U = mu$, so that:

$$U = mu(\rho,s) = mu(m/V, S/m).$$

This means that the internal energy of the flu depends on m_1 and m_2 only through the combinati $m = m_1 + m_2$; so that, although we regard the bu liquid as containing two components, it will beha thermodynamically as if it were composed of a sin substance. The observed range of equilibrium poin for the vapour and the liquid then finds an immedia explanation if we allow this to be determined, the liquid side, by the function $U(V,S,m)$ of equ tion (5).

As regards the proportion of the normal to t superfluid components for temperatures below t λ point, the thermodynamics has apparently prediction to make unless some further hypothe is made. This is not surprising, however, since t theory developed in this communication would clear be applicable to any equilibrium mixture of tv isomeric components. In this connexion, a con parison with the theory of allotropy put forward A. Smits[3] might be of interest.

Finally, we notice that additional support for t hypothesis here put forward is offered by the follo ing derivation of the formula for the thermo-mecha ical effect. Suppose that two separate masses liquid helium II are connected by means of a ve fine capillary tube. On the assumption that on the superfluid can pass along this capillary, the con dition for both masses to be in equilibrium states that the chemical potential of the superfluid con ponent should have the same value in each. B from equation (5) it follows that the chemical pote tial of the superfluid component is given by:

$$\left(\frac{\partial U}{\partial m_2}\right)_{m_1,S,V} = \left(\frac{\partial U}{\partial m}\right)_{m,S,V} = g, \qquad ($$

where g is the Gibbs's function per unit of mass the bulk fluid, namely:

$$g = u - sT + p/\rho. \qquad ($$

Therefore, the equilibrium condition for the tw connected masses A and B is

$$g_A = g_B. \qquad ($$

If, now, the states of the two masses differ on slightly, the equilibrium condition becomes

$$\delta g = 0, \qquad ($$

that is,

$$-s\delta T + \delta p/\rho = 0, \qquad (1$$

and

$$\delta p/\delta T = \rho s,$$

which is the accepted formula for the therm mechanical effect first derived by H. London[4] o the assumption that the superfluid component h zero entropy.

It is clear that the derivation of the formula f the thermo-mechanical effect just given should appl in theory at least, to any equilibrium mixture two isomers divided into two masses separated by membrane permeable only to one of the two con ponents. It is difficult, however, to see how th theory could apply in practice to any mixture apa m liquid helium II, or an analogous substance, if ch exists; since a temperature difference across a mi-permeable membrane separating two masses of ch a mixture would normally lead to a flow of at, by means of the permeable component, which uld ultimately result in the disappearance of this fference. In the case of liquid helium II, however, nere the semi-permeable membrane is replaced by fine capillary through which only the superfluid mponent may pass, a continuing temperature fference is possible because the superfluid, having ro entropy, is entirely incapable of transporting y heat from one container to another. If this alysis is correct, the supposed zero entropy of the perfluid component has a practical rather than a eoretical importance for the thermo-mechanical fect in liquid helium II.

Note added in proof. The more general relationship $p/\partial T)_B = \rho s$ may be derived immediately from quation (8) by varying conditions in A while keeping ose in B constant.

Molecular Weight and Volatility

I wish to direct attention to the fundamental fect of molecular mass on volatility, since it does ot support the widely accepted view that volatility creases with increase in molecular weight. The tter view relies on the various *empirical* relationships between molecular weight and boiling point, ut it has no theoretical basis. Indeed, detailed guments will be presented elsewhere suggesting at these empirical relationships are fortuitous and at the apparent increase in boiling point with molecular weight is due to other causes. By contrast, e *fundamental* effect of mass on volatility has a eoretical background and affords a rational explanaon of certain boiling-point 'anomalies'.

The fundamental effect is clearly revealed by the omparison of vapour pressures of compounds differg only in isotopic composition ('isotopic molecules'). hese comparisons are least complicated by differences intermolecular forces, and it can be assumed that ifferences in vapour pressures are due to the effects f mass alone. The relative vapour pressures of sotopic molecules' vary in a complex manner, and is intriguing to find that the lighter species is not lways the more volatile. In fact, the review by lusius[1] of hydrogen and deuterium compounds hows that the relative vapour pressures vary with emperature in the sense that higher temperatures avour the volatility of the heavier species. Similar ehaviour by other 'isotopic molecules' was reported y Urey[2] and Stokland[3]. However, this peculiar ehaviour is explicable in terms of statistical thermoynamics[1,3,4] although a rigorous treatment seems to e confined to simple cases such as that given by bbelohde[5].

If this mass-effect is fundamental, then it should e a general phenomenon recognizable whenever vapour pressures of two compounds are compared. However, it is a second-order effect usually obscured by the greater effect caused by differences in intermolecular forces, and is only disclosed in favourable circumstances, for example, isotopic molecules. Nevertheless, a novel example of this phenomenon was recently reported by Bradley, Mehrotra and Wardlaw[6]. They found that some tetra-alkoxides of hafnium, $Hf(OR)_4$, were more volatile than the corresponding alkoxides of the lighter element zirconium, and preliminary vapour-pressure measurements showed the molar heats of vaporization of the tertiary amyloxides $M(OCMe_2Et)_4$ (M = Zr or Hf) to be practically equal. Clearly, because of the equalization of intermolecular attraction, due to shielding of the central atom, the fundamental effect of mass on volatility is being asserted in a 'super-isotope effect'. Moreover, this theory predicts a super-isotope effect as a general phenomenon occurring in centro-symmetric systems such as $M^{I}X_n$ and $M^{II}X_n$, where M^{I} and M^{II} are n-valent elements with nearly identical atomic radii and X is a univalent shielding group. Besides zirconium and hafnium, it seemed likely that compounds of niobium and tantalum and also molybdenum and tungsten might fulfil these conditions. A survey of the literature revealed that this is indeed the case, as is shown in Table 1, which gives data for pairs of compounds in which the heavier species is the more volatile.

Table 1

	NbF_5 : TaF_5 (ref. 7)		$NbCl_5$: $TaCl_5$ (ref. 8)		MoF_6 : WF_6 (ref. 9)	
Formula weight	187·9	275·9	270·2	358·2	210·0	297·9
Boiling point, ° C.	234·9	229·2	254·0	239·3	35·0	17·5
Radius of central atom (A) (ref. 10)	1·34	1·34	1·34	1·34	1·36	1·37
Molar heat of vaporization (k.cal./mole)	12·9	13·0	13·2	13·6	8·34	8·69

The relative boiling points of these 'anomalous' pairs are quite inexplicable in terms of the conventional empirical rule connecting volatility and molecular weight, yet this behaviour is expected on the basis of what is here proposed as the fundamental effect of molecular weight on volatility. This theory will be presented in full elsewhere; meanwhile, experimental work is proceeding to test further these ideas.

APPOINTMENTS VACANT

APPLICATIONS are invited for the following appointments on or before the dates mentioned:

DEMONSTRATOR/JUNIOR LECTURER IN ANATOMY—Prof. D. V. Davies, Anatomy Department, St. Thomas's Hospital Medical School, London, S.E.1 (August 19).

ASSISTANT, Grade A (with a special mathematics degree, or a general honours degree, including pure and applied mathematics, or an engineering honours degree including mathematics), IN THE MATHEMATICS DEPARTMENT—The Clerk to the Governors, Woolwich Polytechnic, London, S.E.18 (August 21).

LECTURER (preferably with a special interest in the strength of materials) IN THE DEPARTMENT OF MECHANICAL ENGINEERING—The Registrar, The University, Liverpool (August 21).

SCIENTISTS (with a good honours degree, or equivalent, in engineering or physics, and some relevant postgraduate experience in any of the following fields—light engineering development, pneumatic and/or hydraulic mechanism design, design of light electro-mechanical mechanisms, optical mechanisms), in the Central Research Establishment II of the National Coal Board, Isleworth, Middlesex, for work concerned with the study of methods of establishing suitable instrumentation for use in mines, and to design, develop and prove instruments required in all aspects of mining, and research into mining techniques—The National Coal Board, Establishments (Personnel), Hobart House, Grosvenor Place, London, S.W.1, quoting TT/815 (August 26).

GEOLOGISTS (with a university degree, preferably with honours, or equivalent, with all the subjects of geology at third year standard; or other such qualifications and experience as considered suitable), and GEOPHYSICISTS (with a university degree, preferably with honours, or equivalent, with a major (three year) pass in geophysics, physics, geology, mathematics or other appropriate subject) in the Department of National Development, Commonwealth of Australia, for work with the Bureau of Mineral Resources—The Senior Representative, Department of National Development, Australia House, Strand, London, W.C.2 (August 27)

SENIOR SCIENTIFIC OFFICER (with a first- or second-class honours degree in physics or chemistry, and at least three years subsequent experience), to carry out operational research in the field of radiation protection, develop specialized methods of identification and measurement of radioactive contaminants and apply the results to the practical control of radiation hazards in laboratories and plants—The Establishment Officer, Atomic Energy Research Establishment, Harwell, Berkshire, quoting 2/103/110 (August 27).

LECTURER (with experience in the field of interconnected power systems) IN ELECTRICAL ENGINEERING, at the University of Sydney, Australia—The Secretary, Association of Universities of the British Commonwealth, 5 Gordon Square, London, W.C.1 (Australia, August 28).

ASSISTANT IN BOTANY—The Secretary of University Court The University, Glasgow (August 31).

LECTURER IN THE DEPARTMENT OF BACTERIOLOGY—The Secretary, The University, Edinburgh (August 31).

ASSISTANT LECTURER (with an honours special degree in geography) IN GEOGRAPHY—The Secretary, Bedford College, Regent's Park, London, N.W.1 (September 1).

DEMONSTRATOR IN GEOLOGY—The Registrar, The University, Nottingham (September 4).

RESEARCH ASSISTANT (with a good honours degree in botany, chemistry or biochemistry, and with experience of handling and growing micro-organisms) IN THE DEPARTMENT OF BOTANY, to work on the metabolism and photosynthesis of micro-organisms—The Secretary, University College London, Gower Street, London, W.C.1 (September 4).

SENIOR LECTURER IN ENGINEERING, and LECTURERS (2) IN ENGINEERING—The Registrar, The University, Manchester 13 (September 4).

DEMONSTRATOR or LECTURER IN PHARMACOLOGY—The Registrar, The University, Leeds 2 (September 6).

LECTURER or ASSISTANT LECTURER (with qualifications and experience in chemical engineering or a branch of chemical technology), IN THE DEPARTMENT OF CHEMISTRY, University College of the West Indies—The Secretary, Inter-University Council for Higher Education in the Colonies, 1 Gordon Square, London, W.C.1 (September 11).

LECTURER (with an honours degree and some practical experience) IN MECHANICAL ENGINEERING—The Registrar, The University, Leeds (September 13).

SENIOR SCIENTIFIC OFFICER (with a first- or second-class honours degree in metallurgy or equivalent qualification, and at least three years postgraduate metallurgical research experience) at the Ministry of Supply London Headquarters, to assist in research and development work on metals and their alloys for aircraft construction, and in the initiation and arrangement for experimental work in the Universities and Industrial Laboratories—The Civil Service Commission, Scientific Branch, 30 Old Burlington Street, London, W.1, quoting S 4364/54 (September 14).

READER IN ASIAN ANTHROPOLOGY at the School of Oriental and African Studies—The Academic Registrar, University of London, Senate House, London, W.C.1 (September 27)

ASSISTANT LECTURER (with special qualifications and interests in petrology) IN GEOLOGY—The Registrar, University College of North Staffordshire, Keele, Staffs (September 30).

LEVERHULME FELLOW AND LECTURER (with considerable experience of research work in nuclear physics, and preferably between the ages of 25 and 35 years) IN THE DEPARTMENT OF PHYSICS—The Registrar The University, Liverpool (October 16).

CHAIR OF AGRICULTURE at Rhodesia University College—The Secretary, Inter-University Council for Higher Education in the Colonies, 1 Gordon Square, London, W.C.1 (October 18).

ASSISTANT LECTURER IN THE DEPARTMENT OF CHEMISTRY, Makerere College, University College of East Africa—The Secretary, Inter-University Council for Higher Education in the Colonies, 1 Gordon Square, London, W.C.1.

BIOCHEMIST or ORGANIC CHEMIST, Experimental Officer or Assistant Experimental Officer grade in the Insecticides Department, to assist in work on insect biochemistry in relation to the mode of action insecticides—The Secretary, Rothamsted Experimental Statio Harpenden, Herts.

CHEMISTS, Scientific Officer grade (with a first- or second-cl honours degree or equivalent in chemistry, and with research e perience, preferably in physical chemistry), at various research statio of the Ministry of Supply, mainly in the south of England—T Ministry of Labour and National Service Technical and Scienti Register (K), 26–28 King Street, London, S.W.1, quoting F.546/54

DEPARTMENTAL RESEARCH ASSISTANT (with a degree in physics chemistry) to develop and maintain techniques applied to the investig tion of macromolecules in solution (for example, sedimentation, diffusio light scattering, etc.)—Dr. P. Johnson Department of Colloid Scienc The University, Cambridge.

FISHERIES OFFICER (with an honours degree in a natural scienc with an emphasis on biology) in H.M. Colonial Service, Nigeria, carry out applied and operational research into peasant fish culture- The Director of Recruitment, Colonial Office, Great Smith Stree London, S.W.1, quoting BCD.65/14/01.

LECTURER IN EDUCATION at the University of Malaya, Singapore- The Secretary, Inter-University Council for Higher Education in th Colonies, 1 Gordon Square, London, W.C.1.

PRINCIPAL SCIENTIFIC OFFICER (with a first- or second-class honou degree in chemistry, or equivalent qualification, together with ma years research experience in applied chemistry), to direct and supervi the work of a Materials Development and Advisory Section—Seni Recruitment Officer, Atomic Weapons Research Establishmen Aldermaston, Berkshire, quoting 201/W G.E./2.

RESEARCH ASSISTANT (with a good honours degree in geolog preferably with emphasis on mineralogy, petrology or structur geology) IN THE DEPARTMENT OF GEOLOGY—Head of Departmen Department of Geology, University College, Science Buildings, Merri Street, Dublin.

RESEARCH FELLOW (graduate in zoology or veterinary science, an prepared to undertake teaching duties as well as research) IN PARASITOLOGY in the Faculty of Veterinary Science—The Registra University of Queensland, Brisbane, Queensland, Australia.

SOIL CONSERVATION OFFICER (with a degree in agriculture, and least five years experience of the principles and practice of soil co servation), in the Agricultural Department, Nigeria, for duties whic will include the design and layout of soil conservation schemes an the training of staff (Ref. BCD.63/14/025), and an AGRONOMI (with a degree in agriculture or a related subject, and preferabl with postgraduate research or advanced field experience and som experience of simple surveying), in the Somaliland Protectorate, t supervise agricultural experimental work with special reference t dry farming under semi-arid conditions, and to develop, in co-oper tion with a Hydrologist and Soil Surveyor, flood irrigation exper mental pilot schemes etc. (Ref. BCD 63/5/04)—The Director o Recruitment, Colonial Office, Great Smith Street, London, S.W.1 quoting appropriate Ref. No.

TECHNOLOGICAL AND TECHNICAL EDUCATION IN BRITAIN

THE very guarded statement which the Chancellor of the Exchequer made in the House of Commons on July 13 indicates that official policy for technological education in Great Britain is at last taking shape, though there was no indication of any policy for technical education which should be developed *pari passu*. As already noted in *Nature* of July 17 (p. 111), Mr. R. A. Butler stated that, in accordance with his request of July 1953, the University Grants Committee had submitted its report and recommendations for the development of higher technological education outside London, and that, after considering its recommendations, he had approved plans for developments, mainly at Glasgow, Manchester, Leeds and Birmingham. Mr. Butler indicated that provision was also made for developments elsewhere; but that they would take place at institutions already in receipt of recurrent grants on the recommendation of the University Grants Committee. It would be necessary, accordingly, to increase the resources available to the University Grants Committee, both for recurrent and non-recurrent purposes, in the last three years of the quinquennium 1952–57.

The Chancellor is now considering the timing of these developments, some of which, he hoped, would start in the next academic year; and the further statement, which he promised to make in due course, will no doubt give details of the proposed increase in the vote for the University Grants Committee. Those details, if the Government is reasonably generous, should themselves attest the wisdom of the Committee's refusal to disperse over too wide a field the strictly limited allocation which can be spared to higher technological education from the national resources at the present time. Meanwhile, the University Grants Committee has rightly resisted the temptation to spread those resources over six or more institutions as suggested in the Percy Report of 1945, still more over the fifteen or twenty regional colleges suggested in the report on the Development of Higher Technological Education submitted to the summer meeting of the Association of Principals of Technical Institutions and the Association of Technical Institutions* last June. That report, which followed broadly proposals advanced by Principal J. C. Jones to the latter Association in February, was concerned with securing adequate regional cover; but it failed to distinguish between technical and technological education. Nevertheless, the report proposed that the selected colleges should all receive contributions from the central government amounting to not less than 75 per cent of the agreed net expenditure. It was also proposed that these colleges should provide advanced courses and facilities for postgraduate studies and research for a region rather than the area of a particular local education authority, and that, accordingly, they should be financed by grants covering a period of not less than three years and administered solely by a governing body on which the industry and commerce of the region as well as local education authorities should be represented.

---

*Association of Principals of Technical Institutions and Association of Technical Institutions. Report on the Development of Higher Technological Education. (Summer Meeting—Southport, 10th–12th June, 1954.) Pp. 7. (London: Association of Technical Institutions, The Polytechnic, London, W.1, 1954.)

It may well be a matter for consideration how far it is desirable for technical education to be given more independence from local authority control; continuity, greater freedom and improved conditions of service for the staff of technical colleges could be bought too dearly if local interest and co-operation should be adversely affected. The development of technical education depends largely on such local interest and co-operation and, to the extent to which they are secured even under the existing arrangements, it should be possible continuously to improve conditions so that staff of the requisite quality is attracted and retained, and provided with the facilities for effective research as well as teaching. What needs to be remembered is that the technical colleges are doing a job no less important than, but complementary to, that of the technological institutions. It is not a matter of one type of institution being inferior to the other, but of providing each with the most appropriate conditions for efficiency, and apportioning the available resources between the two types of institution in accordance with the needs of the country.

That is the reason for some doubt, in the absence of fuller information, as to whether the resources available for higher technological education are not even now being distributed too widely. Great Britain clearly cannot afford the resources necessary for developing five major technological institutions of the type of those at Massachusetts or Delft, nor should it be assumed as yet that that is the intention of the Government. All that can be said at present is that the Government's plans contemplate the development of the Imperial College of Science and Technology into a major technological institution of university rank. It can safely be assumed that such development will not diminish the fructifying interaction and intercourse between the pure and applied sciences, or between them and other fields of study which the authorities of that College have shown themselves so anxious to promote. The proposals announced on July 13 appeared to contemplate the development as independent institutions of university rank of the Royal Technical College, Glasgow, and the College of Technology, Manchester; but Mr. Butler's subsequent statement of July 20 seemed to deny this, though in view of existing relations between the latter College and the University of Manchester the position is not clear. Lord Woolton has already indicated that it was contemplated that the latter College should become independent, with its own governing body and a substantial government grant, and the implications of the Government's proposals are already being considered by the Manchester City Council.

The Manchester College of Technology has close ties with the University of Manchester, and Lord Salisbury, during his visit to Manchester, indicat that these relations would be maintained under t new arrangement. Nor is it likely that in the develo ments at Glasgow there will be any interruption such interaction and intercourse, or any excessi segregation of specialities. At Leeds and Birmingha it would appear that developments will procee within the framework of the existing universi departments of technology, and so far as the Gover ment's policy is disclosed, accordingly, it wou appear to take care of the great danger of segregatio against which Sir Philip Morris, Sir Richard Sout well, Lord Eustace Percy and others have warned so plainly and to be seeking to improve and develo existing institutions rather than create entirely ne ones. Three clear lines of evolution can be discerne none of which appears likely to depart too far or t abruptly from our tradition of multi-purpose institutions, yet all of which would appear to offer reasonab scope for experiment with new ideas and ne methods.

Discussion on the expansion of higher technological education in Britain should in future tur more on the tactics to be used rather than on th policy to be pursued, subject to the reservation tha no policy for higher technological education will mee the nation's needs without an adequate policy fo technical education. Education must be viewed a a whole, and the available resources—finance materials and man-power—allotted in accordanc with some reasoned appraisal of the situation as whole and of the complex interrelations of which th shortage of science teachers has at least helped t make the nation better aware. Technological education cannot be expanded without due regard to th general needs of the universities, of technical education and of secondary education, and indeed of adul education in general. As the Percy Committe pointed out, technical education needs to be surveyed and planned as a whole, and in the field o adult education as well as in its technological studie it requires co-ordination with university education.

This emphasis of the Percy Committee on diversit of function has frequently been ignored in subsequen discussions. Had the comment of the report that diversity of function is not inconsistent with equality o status between the technical colleges and the institutions specifically for higher technological educatio been heeded, the futile discussions about awards would scarcely have persisted into the recent report from the Association of Technical Institutions and the memorandum of the Parliamentary and Scientific Committee. Fortunately, some at least of the papers such as that of Mr. F. H. Perkins, given at the Conference of the Associations of Technical Institutions and of their Principals, showed a clear idea of the situation and of industry's need for both technicians and technologists.

Mr. Perkins, in his paper on industry and technical colleges, to some extent followed ideas expressed by Dr. P. F. R. Venables at the North of England Educational Conference (see *Nature*, January 30, p. 197); but the plan for which he pleaded would concentrate major developments in two or three technical lleges rather than the twelve or fifteen suggested Dr. Venables. These, however, would provide ll-time and sandwich courses for selected students an advanced level, organized on a residential basis, which the students could participate fully in the mmunal life of the college, much as Dr. Venables d urged. These developments would be accomnied by a further increase in the number of students king first degrees in science and technology at the iversities, so as to reduce a deficiency in the supply scientists and technologists, which by 1955 is kely to exceed considerably that forecast in the arlow Report.

This policy, so far as can at present be judged, ay be nearer to that which the Chancellor of the xchequer contemplates than the more diffused rogramme suggested by Dr. Venables or Mr. Jones. r. Perkins was dealing more particularly with dustry's requirements for recruits capable in due urse of filling its more senior posts. Stress was ccordingly laid upon residence, a broad curriculum ased on science and strong seminar activities as the ost likely means of developing the qualities required. he need will not be met by measures which merely rovide increased opportunities for those studying nder the handicap of evening classes or long daily urneys to and from home.

The first need is to provide for the expansion of igher technological education in a way which will upply industry with technologists of the calibre and otentialities it requires ; but that expansion must ot be at the expense of the technicians which it equires in even greater numbers. For the chemical dustry, Mr. Perkins said that the number of such en and women with lesser scientific or technical ualifications and experience required is probably bout fifty per cent greater. To provide such men nd women and also less highly qualified technicians (which for other industries may well outumber technologists by five to one) is the primary esponsibility of the technical colleges and the funcion which has to be most closely related to local eeds. One difficulty in the development of higher echnological education at the Manchester College of Technology is likely to be the College's responsibility or providing the local education authority's national ertificate courses, a responsibility that cannot be ivested until subsidiary colleges are built. The way n which the expansion of technological education is inked with that of technical education could not be etter illustrated.

The corollary of the proposals announced by Mr. Butler is in fact a clear statement of the policy which he Minister of Education proposes to adopt in echnical education. Of that Miss Horsbrugh gave o sign when she was addressing the annual conerence of the Association of Education Committees at Scarborough on June 25. Her claim that at the nd of April £12 million had been spent on building technical colleges since the end of the War, another £18 million on those still under construction and that xpenditure of a further £4·5 million was projected does not amount to a policy, any more than her easonable plea for more co-operation between local authorities or her promise to issue regulations which would minimize the causes of friction in financial arrangements.

It is not only, however, in respect of financial arrangements that a lead from the Minister could help to remove friction and foster co-operation. A clear statement of policy and of the resources to be made available for the development of technical education is essential in order to secure the co-operation of industry, and it might also facilitate the establishment of effective relationships between the colleges of technology and the university departments of technology and the technical colleges. As Miss Horsbrugh rightly pointed out, it is not sound or economically possible for the technical colleges to serve all the needs of an area, and the exact means by which needs, and especially the advanced needs, are best satisfied will vary from area to area. But until some overall picture of the Government's policy and plans can be seen, it will be impossible to remove by reasoned argument and discussion the disappointments, sometimes rooted in local jealousies or history, which the wisest selection is liable to engender, and to secure co-operation and goodwill. The goodwill and understanding of the local authorities are essential, moreover, if conditions of service in the technical colleges are to be such as to attract staff of a calibre to undertake usefully either consulting work or research, and to win and hold parity of status with the institutions for technological education.

BRITISH BIRDS

The Birds of the British Isles

By Dr. David Armitage Bannerman and illustrated by George E. Lodge. Vol. 1: Corvidae, Sturnidae, Oriolidae, Fringillidae. Pp. xviii+356+41 plates. Vol. 2: Alaudidae, Certhiidae, Paridae, Vireonidae, Muscicapidae, Motacillidae, Sittidae, Laniidae, Bombycillidae, Regulidae. Pp. viii+302+41 plates. (Edinburgh and London: Oliver and Boyd, Ltd., 1953.) 45s. net each vol.

THIS is a work on British birds in the grand manner, the like of which one had scarcely expected to see again; one gathers that it has been made possible by the artist's creation of a trust fund to subsidize the reproduction of his plates. The work is sumptuously produced, beautifully illustrated, and written in a leisured style with care and distinction. These two volumes are the first of three dealing with the passerine birds; and from this one can estimate that six or seven volumes in all, of which the rest are to be issued over a period of years, will be required for the complete work.

The author and the artist—Dr. David Bannerman and Mr. George E. Lodge—are both past vice-presidents of the British Ornithologists' Union and are already very well known for their work. Shortly after these volumes appeared, one regretted to hear of the death of Mr. Lodge, although at a great age; but he had completed his series of paintings for this work some years ago, and one is happy to know that it will be illustrated throughout with plates in colour by the foremost ornithological artist of our time and country. These not only serve the purpose of accurate and useful illustration, but they are also pleasing as pictures in high degree.

Dr. Bannerman's professional studies, during forty years at the British Museum (Natural History), have been concerned mainly with the birds of West Africa, on which he is the recognized authority. The present work he describes as the child of his leisure hours, and they have indeed been well spent—in wide reading, in the expert examination of specimens, and notably in the field, all of which forms of study have clearly contributed to the success of the final result. Moreover, he has been at pains to provide a very readable text to match the beauty of the plates, in contrast to the highly compressed summaries with which the writers of most modern works of reference have to be content; in this he has deliberately followed the model of the great ornithologists of a more gracious age, from whose writings he also effectively quotes.

The arrangement is of the usual systematic kind: for each species information is given on identification (with differentiation of races where relevant), distribution at home and abroad, migration, habits and breeding. This is, of course, a well-worked field; but, in addition to bringing information up to date, or amplifying it from hitherto unpublished sources, the author has critically re-examined earlier statements and made his own assessments. (Special acknowledgment is made of the numerous notes supplied personally to Dr. Bannerman by another ornithologist, Dr. H. M. S. Blair.) A special feature is the wealth of information about British migratory species in their other habitats abroad and, where possible, actually on passage: this is a valuable contribution, largely based on Dr. Bannerman's personal observations during the extensive travels that he has for many years undertaken for the express purpose.

There are naturally points on which other experts may differ from the author, some questions of classification and nomenclature being among them. In his preface, Dr. Bannerman indulges some personal views about lines of ornithological study with which he is not in full sympathy; fortunately, however, neither the bionomics of bird populations nor interpretations of bird behaviour are essential to the particular purpose which Dr. Bannerman is in the process of fulfilling so well.

LANDSBOROUGH THOMSON

RESPIRATION IN PLANTS

Plant Respiration

By Dr. W. O. James. Pp. ix+282. (Oxford: At the Clarendon Press; London: Oxford University Press, 1953.) 30s. net.

THAT plants, like animals, absorb oxygen and give out carbon dioxide has been known for well over a century; but the significance of this as a feature of an oxidation of carbohydrate or other material by which energy is released only came to be realized later. To emphasize this as the essential characteristic of respiration, Barnes in 1905 suggested the term energesis; and although this term was not accepted by the generality of botanists, almost all plant physiologists have now for many years regarded respiration in plants as including all those processes in which a substrate is broken dov with release of energy. Thus processes not involvi an oxidation, notably the breaking down of sug to carbon dioxide and ethyl alcohol, are includ in respiration and are distinguished from norr respiration as 'anaerobic' respiration. During th past ten years or so there has been a tendency limit the application of the term respiration to tho processes in which sugar or some other substrate broken down by oxidation and to use the ter fermentation to denote those processes previous known as anaerobic respiration. It is, howeve quite impossible to give any detailed account plant respiration without also dealing with th degradation of sugar in absence of oxygen; and the opening pages of this treatise on plant respiratic Dr. W. O. James gives reasoned and cogent arg ments for using the term 'plant respiration' to incluc all those processes in which complex substanc undergo changes that in the aggregate lead to diminution of free energy.

Dr. James's account of plant respiration is ver comprehensive, and the various aspects of the subje are dealt with in detail. The arrangement of th material, if to some degree unusual, is satisfactor and, indeed, successful. The earlier chapters on th rate of respiration, which includes temperatu effects, respiratory drifts and the respiratory quotien deal with information which for the most part ha been well established for many years. The followin chapter on respirable materials includes a discussion o the important topic of the phosphorylation of carb hydrates. The remaining five chapters of the bool comprising somewhat more than half of the whole tex which are headed glycolysis, oxygen effects, oxida tion mechanisms, oxidation stages in respiration an connexions with other processes, deal with what i often described as the mechanism of respiration. I is with the aspects of respiration considered in thes chapters that our knowledge of the subject ha developed most during the past twenty years, development which has been brought about in n small measure by Dr. James's own researche Whereas some twenty years ago so little was know of the course of the breakdown of the respirator substrate in plants that it was little more than matter for conjecture, we now have a complet scheme for the course of degradation of carbohydrat to carbon dioxide and water which, if not proved, i at least credible and in harmony with experimentall discovered facts. These chapters, in particular, wi be read with interest by all wishing to acquir detailed information of recent work on the mechanism of respiration.

It seems clear that respiration supplies the energy for certain syntheses in plant cells and for the intak of salts into cells against concentration gradients The problems of the way in which the energy provided by respiration is utilized in these processe are still unsolved, as a perusal of Dr. James's last chapter shows. But many plant cells do not appea to be concerned in such processes or, indeed, in any activity requiring a supply of energy, and yet they respire. What then is the general significance o respiration? This question is dealt with in the concluding paragraphs of Dr. James's book; but he decides that there is at present no valid evidence either in support of, or against, the idea that respiration is essential for protoplasmic maintenance. With this conclusion the present reviewer is in complete agreement, and, indeed, he is far from convinced at respiration is necessary for cells to remain alive, distinct from actively living.

Dr. James is to be congratulated on producing a asterly and scholarly monograph on plant respira- on in which the researches of more than a century e critically considered and ably presented. This ork, by a recognized authority on his subject, forms valuable addition to the literature of plant ysiology.

W. STILES

TREATISE OF PALÆONTOLOGY

raité de Paléontologie

ublié sous la direction de Prof. Jean Piveteau. ome 3 : Les formes ultimes d'Invertébrés ; morph- ogie et évolution ; Onychophores. Par C. echaseaux. Arthropodes, Proarthropodes. Par C. echaseaux et G. Waterlot. Trilobites. Par P. upé. Crustacés. Par C. Dechaseaux, N. Grekoff, . Roger, H. et G. Termier. Myriapodes, Insectes. ar D. Laurentiaux. Mérostomes, Arachnides. Par . Waterlot. Échinodermes, Hétérostélés, Cystidés. ar L. Cuénot. Blastoïdes. Par F.-M. Bergounioux. drioastéroïdes. Par J. Piveteau. Crinoïdes, Stel- roides, Ophiocystoïdes. Par G. Ubaghs. Echinides. ar H. et G. Termier. Holothurides. Par M. eflandre-Rigaud. Stomocordés, Ptérobranches et raptolites. Par G. Waterlot. Machaeridiens, onulaires, Hyolithes, Tentaculites. Par H. et G. ermier. Pp. viii + 1063 + 17 plates. (Paris : Masson t Cie., 1953.) Broché 9,600 francs. Cartonné toile 0,320 francs.

VOLUME 3 of the "Traité de Paléontologie" includes all the Invertebrata not dealt with in he first two volumes. Of editorial practices already riticized[1], authors and dates of the various taxonomic nits are still too seldom given, and the type, or any pecies of the genera mentioned, is too often omitted. ome pre-Linnæan names of Echinoid genera are also ncluded. The scale of magnification of the figures usually indicated, however, and the high standard f printing and illustration is well maintained.

The Onychophora, scarcely known fossil, are reated in a brief and lucid essay which indicates the mportance of this group to theories of annelid–rthropod relationship. An important chapter on he basic characters and phylogeny of the Arthropoda s useful as an introduction to this vast phylum. Of he chapters on the various classes, that on the rilobitomorpha meets the requirements of a text-ook, but the Trilobita are handled in a speculative ashion and numerous new family-group units are roposed. The author's enthusiasm and ability have evertheless produced a well-documented account ith excellent illustrations. The Crustacea are well, f conservatively, dealt with ; but more space might ave been allotted to the Ostracoda in view of their conomic importance, and no chapter on the Cirripedia an be adequate that ignores the work of the late T. H. Withers, especially his three catalogues pub-ished by the British Museum (Natural History). Of he remaining chapters on Arthropoda, that on the Insecta, though permitting some taxonomic novelties, ar surpasses anything previously available.

The first two chapters on Echinoderms are the last f many profound contributions by the late L. Cuénot nd deserve the respect due to all his work. The ections on the Crinoidea and Stelleroidea are beautifully fitted to the scale of the "Traité", though the new ordinal and family-group names in the former should not have been proposed here. The chapter on the Echinoidea is scarcely worthy of the rest of the "Traité" or of the tradition of French work in this group. The morphology is inadequately illustrated, and the drawings in the systematic section are clumsy and too often taken from poorly preserved material. The concluding six chapters call for no special comment, though that on the Graptolites seems rather severely compressed.

Each of the first three volumes of the work includes more speculative matter than would a British work of the same kind, and they are not primarily useful as systematic reference books in all groups. They should not be placed in the hands of students without caution. The durability of their value, therefore, rests on a somewhat uncertain basis ; but the standard of morphological and ontogenetic information is high, and it is these introductory sections of each chapter that are likely to prove of most use. Many of the systematic sections are excellent ; but the average level is lowered by a few chapters which weaken the authority of the whole.

WILLIAM HERSCHEL : HIS WORK AND PERSONALITY

William Herschel

Explorer of the Heavens. By J. B. Sidgwick. Pp. 228 + 4 plates. (London : Faber and Faber, Ltd., 1953.) 12*s.* 6*d.* net.

THROUGHOUT the history of astronomy, there are one or two names which stand out in sharp relief when one begins to consider the observational side of the science. Hipparchus, Tycho Brahe and Sir William Herschel are three which immediately come to mind. Each made substantial contributions, and each provided fine sets of observations which were of vital importance to those who followed. But while it is virtually for their observations alone that we remember Hipparchus and Tycho Brahe, William Herschel is noted not only for his outstanding observations but also for the great theoretical use he made of them ; Herschel was, in fact, a great theoretical astronomer as well as the observer *par excellence*.

An able and sympathetic account of this surprising genius is given by Mr. J. B. Sidgwick in this book, in which he concerns himself especially with Herschel the man. He begins, appropriately, with the Herschel family in Hanover, and follows them through their various vicissitudes which finally resulted in William and his elder brother Jacob settling in England. Mr. Sidgwick has a great feeling for his subject ; indeed, we soon find the formal "Herschel" being replaced by the more familiar "William", although a return to "Herschel" occurs when the narrative becomes concerned with his theoretical work. The book usefully brings out the success which attended Herschel's work as a professional musician and gives an admirable picture of the keen amateur astronomer who, in his diary, reported with such obvious relish that ". . . I gave up much time to astronomy and also attended many scholars. Some of them made me give them astronomical instead of musical lessons". Mr. Sidgwick also gives graphical descriptions of Herschel's labours as a telescope maker and shows how his careful application to this work enabled him to produce instruments of a quality far surpassing anything then available; so good, in fact, that the magnifying powers he was able to use were for a time doubted by his contemporaries.

But it is in William Herschel's prowess and assiduity as an observer that his greatest claim to fame lies; and while it may be felt that Mr. Sidgwick gives more place to biographical details than to Herschel's astronomical work, nevertheless we do obtain a real sense of the perpetual observing which Herschel carried out as well as of the devoted assistance rendered by his sister Caroline. As to Herschel's pioneering endeavours in the theoretical field, in which he drew on his own unique fund of observational material, it is here that the book is not quite so satisfactory, as is to be expected, perhaps, in one written to have so wide an appeal as is clearly Mr. Sidgwick's aim. All in all, however, this volume, written with style and imagination, gives a good portrait of one of astronomy's greatest figures. It is free from any gross errors and, with its short but useful bibliography, is to be recommended.

C. A. RONAN

1950 INTERNATIONAL CONGRESS OF ELECTRON MICROSCOPY

Comptes Rendus du Premier Congrès International de Microscopie Électronique

Paris, 14–22 Septembre 1950. Mémoire hors série No. 1. Publié par la Société Française de Microscopie Théorique et Appliquée avec le concours du Centre National de la Recherche Scientifique. Pp. viii + 768. (Paris: Éditions de la Revue d'Optique Théorique et Instrumentale, 1953.) 8000 francs.

THE First International Congress of Electron Microscopy, held in Paris in 1950, attracted such a great number of participants that the report of its proceedings constitutes in itself a survey of the whole subject of electron microscopy as it stood at that time. In a short review it is only possible to indicate its scope. Electron optical theory claims thirty-one papers, but the design and construction of the microscope itself only eight papers; there are twelve on electron diffraction. Metallurgical applications, in eighteen papers, include work on metal physics as well as on more immediately practical problems of both ferrous and non-ferrous metallurgy. Twenty contributions on chemical applications range from pigments and polymers to photographic emulsions and clays. Biological applications not unnaturally attracted most attention, with forty-four papers which dealt with specimen preparation techniques (fixation, drying, sectioning, replicas), on one hand, and on the other with the use of the electron microscope in almost every type of biological and medical problem (viruses, bacteria, cancer, nerve, muscle, blood cells, teeth).

In two respects the Congress report is more informative than the meeting itself: first, it was physically impossible to attend all the sessions, and now every paper is available in print; and secondly, a large group of papers from Japan (twenty-four) which were read in title only are now printed in full. Two complaints may be made against the repor it appears almost three years after the meetin although the manuscripts should have been su mitted before the meeting, and the price is high. Th explanation in both cases probably goes back to th desire to include every contribution in full. In such rapidly advancing subject as electron microscop speed is possibly more important than comprehe siveness in publication.

It should also be mentioned that the Paris Congre was not the first in electron microscopy either *facto* or *de jure*: the first meeting of the Internation Commission for Electron Microscopy to be he under the auspices of the International Council Scientific Unions was held this year in London, an prior to the Paris meeting at least two conferenc of an international character had taken place, Cambridge (1948) and in Delft (1949).

V. E. COSSLETT

USE OF DIMENSIONS IN PHYSICS

Dimensional Methods and Their Applications

By Dr. C. M. Focken. Pp. viii + 224. (London Edward Arnold and Co., 1953.) 30s. net.

LIKE most of the basic principles of science, th subject of dimensions has grown up rathe untidily; it is presented differently and with differen conventions in almost every department. Th appearance of this book, with its suggestions fo standardization and its careful consideration of man of the difficulties involved, is therefore very welcom If it reads in places somewhat like a tract, this i only because the author wishes to present every sid of each problem and yet to make his own fir recommendation about which side to accept.

The subject is covered very well, with ampl references and quotations from some of the mor important papers. The sections on the dimension of thermal and electrical and magnetic quantitie will be found by most physicists to be extremel helpful.

In such a thorough treatment, it seems strang that the possibility of vector notation has not bee considered. This could be very useful; for example the dimensions of energy and of the moment of force are both (ML^2T^{-2}); but physically they ar quite dissimilar, the former being a scalar and th latter a vector. If a distinction could be made, i would be possible to make use of the result that al terms of an equation should be either scalar o vector, as well as dimensionally similar.

One point with which physicists will be inclined t disagree is the author's rejection of the physical basi of the principle that the argument of a transcendenta function (for example, e^x) should be dimensionless This basis seems so reasonable that the reviewer, a any rate, will continue to make use of it when h has need.

The book is well bound; but the printing is rathe displeasing. It appears to be reproduced fron electric typewriting; but the spacing of the word and even of the letters is not up to goo printing standards, and the right-hand edge of th type is often rather ragged. It is to be hoped tha this method of printing books will not be copie until it is a great deal better.

H. LIPSON

he Kalahari Sands of the Lunda (N.E. Angola), their Earlier Redistribution and the Sangoan Culture

Companhia de Diamantes de Angola: Museu do Dundo. Subsídios para a História, Arqueologia e Etnografia dos Poros da Lunda. Publicacoes Culturas No. 20. By J. Janmart. Pp. 65. (Lisboa: Companhia de Diamantes de Angola.) n.p.

SENHOR J. JANMART, chief of the prospecting service of the Companhia de Diamantes de Angola, has spent many years in studying the Kalahari Sands and their immediate derivatives. The Sands themselves fall into a threefold chronological series: Lower Kalahari (Kamina formation); Middle Kalahari (silcrete); and Upper Kalahari Kalahari Sands). All three deposits are pre-Pleistocene in age. Following on the deposition of the Upper Kalahari Sands denudation and redeposition have taken place, and a series of beds of redistributed sands has been determined. The volume under eview deals with the first two of these post-Upper Kalahari beds and their correlation with archæological discoveries.

The Upper Kalahari Sands and the earliest of the redistributed sand layers so far have yielded no human artefacts. If the Upper Kalahari Sands are assigned to a late Pliocene date, the succeeding layer may perhaps be considered as early Pleistocene, since the succeeding layer (redistributed sands (II)) contains Sangoan industries. Actually two typical Acheulean coups de poing have been found in a deposit which seems to date immediately anterior to the deposition of the redistributed sands (II), and this is what one would expect since the Sangoan culture is post-Acheulean in date and belongs to the Middle Stone Age complex both in East and South Africa.

This volume under review is an interesting contribution to knowledge and is well illustrated both in the way of half-tones and maps, sections and reproductions of stone implements. Those of us who read Portuguese with some difficulty are grateful to the author for having so considerately written the volume in English.

M. C. Burkitt

Australian and New Zealand Botany

By Prof. J. McLuckie and Dr. H. S. McKee. Pp. xx+758. (Sydney: Associated General Publications, 1954.) £Aust.4 4*s*.

ONE of the problems of teaching elementary botany in the Antipodes is that the text-books are European. The enthusiastic teacher may illustrate his lectures by the use of Australian plants, and he will be obliged to use some local types in the laboratory; but the student will still turn to standard British texts, and will read about fertilization in *Fucus* although he has seen it in *Hormosira*, and about the male cones on *Pinus* although he has dissected them on *Macrozamia*. There has long been need of a text-book up to first-year university standard based on plant life as the Australian student sees it, not as the professor from England remembers it. Drs. McLuckie and McKee have now supplied this need admirably. Their book amply covers a conventional first-year course. It is well illustrated with large numbers of original drawings. There are a full and up-to-date discussion of physiology, and a lucid section on fungi (where most of the types are providentially similar for the English and Australian student); a summary, all too brief, on the Australian and New Zealand flora, containing material which has not been assembled before in accessible form; and finally a brief history of botany in Australia and New Zealand. The book is a credit to Australian publishing, which until recently could not have produced such a book as this. It will undoubtedly be the mainstay of generations of Australian and New Zealand students.

E. A.

Science in Everyday Life

By Ellsworth S. Obourn, Prof. Elwood D. Heiss, and Gaylord C. Montgomery. Pp. viii+612+16 plates. 30*s*. net. Teachers Guide for Science in Everyday Life. Pp. 21. 3*s*. net. (New York: D. Van Nostrand Company, Inc.; London: Macmillan and Co., Ltd., 1953.)

THE book is written for young adolescent boys and girls, and aims at developing an interest in science and an understanding of its applications in solving everyday problems. A very broad field is covered; indeed, the book has something of the character of an encyclopædia; but it is designed as a definite teaching course covering a single school year. The 'topic' method is followed as a means of stressing the unity of science, and emphasis is laid throughout on the underlying theme of energy.

With so wide a range of subject-matter the treatment is perforce very superficial, and from the point of view of general science teaching one feels that the authors have at times tried to build too much on what must necessarily be meagre foundations. For this reason the book would find only very limited application in the classroom in Great Britain, where the tendency is rather to narrow the field and so allow more detailed treatment. It would commend itself rather as a personal reference book for the bright thirteen-year-old child with a scientific bent. As such its appeal is enhanced by the numerous good illustrations and diagrams, also suggestions for experiments or observations drawn from common daily experience.

Maurice Ashby

Seventh Congress of the Universities of the Commonwealth, 1953—Report of Proceedings

Edited by Dr. J. F. Foster. Pp. xxxviii+296. (London: Association of Universities of the British Commonwealth, 1954.) 21*s*.

THIS admirably produced report of the proceedings of the Seventh Congress of the Universities of the Commonwealth, 1953, includes the text of the opening addresses at the five main sessions of the Congress and also those given at the two sessions on the special topic of the subject or subjects to-day best fitted to fulfil the part played previously in the university curriculum by the classics, as well as reports of the ensuing discussions. Although there is no index, the layout of the contents is such as to facilitate ready reference to the remarks made by any particular speaker or on any subject discussed. Besides the report of the executive council of the Association of Universities of the British Commonwealth for the period July 1948–June 1953, there are appended a report by the Committee for Commonwealth University Interchange on interchange visits between Commonwealth Universities and a note by the Principal of the University of London on the effect of superannuation schemes on mobility of academic staff within the Commonwealth. The Association is to be congratulated in placing on permanent record so much material of continuing interest in current discussions in a form as pleasant to handle as it is convenient of reference.

THE ROYAL SCOTTISH MUSEUM, EDINBURGH (1854–1954)

By DR. F. S. WALLIS
City Museum, Bristol

THE centenary of an organization provides a suitable opportunity to indulge in a historical survey and to indicate lines of progress for the future. Dr. D. A. Allan, the director, has developed both these themes in an admirable brochure published to commemorate the centenary of the Royal Scottish Museum in Edinburgh.

In common with the history of the majority of museums, the roots of the idea ante-date the actual foundation. In 1812 there was initiated in the University of Edinburgh a Natural History Museum, which though mainly formed for teaching purposes also served the general public to a limited extent. The collections were chiefly zoological; but a certain amount of the then inevitable ethnological material soon appeared.

The middle years of the nineteenth century witnessed a tremendous interest in industrial processes, and eventually, as a result of strong representations in Parliament, in 1854 a sum of £7,000 was voted for the purchase of a site and initial expenses in connexion with the establishment of an Industrial Museum for Scotland. The site, immediately to the west of the University of Edinburgh, consisted of an open space and two buildings. Dr. George Wilson was appointed the first director in April 1855 and later he received the appointment of professor of technology in the University of Edinburgh. This Industrial Museum of Scotland was really intended to be a museum of the industry of the world in special relation to Scotland. Also in 1855 the Edinburgh Town Council, patrons of the University, voted that the Natural History Museum in the Old College be handed over to the same body—the Department of Science and Art—controlling the new Museum. The foundation stone of the building, designed in Venetian Renaissance style, was laid by the Prince Consort in 1861. The first section was the eastern one, nearest the University, and subsequent additions extended westwards and southwards. On May 19, 1866, the first portion was opened formally by Prince Alfred, Duke of Edinburgh, while the most recent addition was opened in 1938. In 1864, to meet the dual functions demanded by two types of museums, the title was changed to the Edinburgh Museum of Science and Art. In view of the wide educational use made of museums in the present day, it is interesting to note that about this time courses of lectures for artisans were organised in natural history, geology, chemistry and natural philosophy at the modest fee of 1*s*. per course.

In the early days the work of the staff was impeded by almost continuous building operations, and the interest of the public was rather retarded by the discomforts of poor entrances and finally the construction of a street along the Museum frontage. Notwithstanding all this, some large attendance figures are recorded and the staff constructed some pioneer natural history groups, built technological models and prepared three catalogues on mineralogy, geology and British Foraminifera. The Museum also commenced to stage loan exhibitions, beginning with art, needlework and art fans, while one of Indian gifts made to H.R.H. the Prince of Wales brought the attendance in 1879 to 647,294. In 1904 the Museum celebrated its jubilee and its name was changed to the present one of the Royal Scottish Museum. Also in this year the building was refloored with oak, the roofs were reglazed—top lighting is a continual bugbear to administrators—and a new heating and ventilating system installed.

Up to this time the Royal Scottish Museum, in common with similar institutions, acquired its collections by gift, purchase or loan. The choice was thus limited by the likes or dislikes of private collectors. Such a state of affairs made it difficult to build up a systematic, comparative or chronological series, and in 1907 Mr. E. Ward was sent to Egypt to take part in archæological excavations and thus acquire material with adequate data. This policy of selective acquisition was soon extended to other Departments in the Museum. In 1910 a report was made concerning the state of local museums in Scotland. Thus was started that fatherly interest which has been such a feature of Dr. Allan's directorship. His influence on local museums to secure greater efficiency can scarcely be over-estimated. In 1930 "The Exhibit of the Month" was introduced, whereby some notable specimens or a new accession could be brought to the special notice of the public. Even at this period of its existence the need for a lecture theatre was stressed, for public lectures given fortnightly were attracting audiences of about two hundred. The priority of this requirement is still being emphasized by the Standing Commission on Museums and Art Galleries. But with the frequent extensions to the buildings and the consequent reallocation of galleries a certain amount of inevitable confusion had arisen. The evacuation of material necessitated by the Second World War gave the opportunity in 1946 for a re-arrangement on simpler lines. Natural history and geology now occupy the eastern block, art and ethnography the centre, and technology the western block. The administrative offices and laboratories are situated in the rear, while the reserve collections are housed in the basement and in one special block. The post-war reorganization also permitted of new schemes of redecoration, and for the first time a complete scheme of colours for walls, staircases, passages and case framings was drawn up with the aim of securing a harmonious background against which the exhibits would be accentuated. The Museum is now administered by the Scottish Education Department at a cost of about £75,000 per year.

The record of achievement concludes with short histories by the keepers of the separate Departments. Mr. Robert Kerr, keeper of the Department of Art and Ethnography, points out that though the original collections were associated with the early Industrial Museum, it was not until 1901 that the present departmental nomenclature was adopted and the acquisitions became more and more associated with the arts—not the graphic ones—and craftsmanship. They include metalwork, ceramics and glass, ivories, furniture and woodwork and textiles. The Main Hall nd large hall beyond provide a display of specimens illustrating European art, Oriental art, primitive art and the civilization of Ancient Egypt. On the first floor are the main comparative series of ceramics, arms, coins, glass and medals. The silver is notable for some excellent Scottish examples. The Textile Gallery shows a representative collection of lace, Persian and Oriental embroideries and early pieces from Egypt and Peru. Upstairs, on the second floor, are galleries illustrative of comparative ethnography, with some outstanding Japanese prehistoric material.

Dr. A. C. Stéphen stresses the association of the early natural history specimens with Prof. Robert Jameson, that outstanding personality who inspired so many Scots to collect in foreign lands. The exhibition galleries comprise fourteen rooms in the eastern half of the building and includes sections devoted to British and foreign birds, British mammals, extinct animals, beasts of prey, large ungulates, proboscideans, reptiles, fish and a recently arranged insect display. The Children's Gallery, with a fine diorama of the foreshore facing Bass Rock, is a striking feature. Mention must also be made of the Type Gallery and the Hall of Comparative Osteology, designed chiefly to meet the needs of students as distinct from members of the general public. The technical equipment of this Department is remarkably complete, and includes two studios for the skinning and mounting of animals, a large de-greasing plant and recently a freezing apparatus is being installed in the basement. The subject of botany is, of course, dealt with in the Royal Botanic Gardens.

Mr. A. R. Hutchieson, keeper, in describing the Department of Technology, naturally refers to the fact that it had its beginnings in the Industrial Museum of Scotland, and even some of its collections go back to the material acquired from world-wide sources following the Great Exhibition of 1851. These are augmented by industrial models and scientific apparatus derived from the Royal Scottish Society of Arts, the Royal Highland and Agricultural Society of Scotland and the University of Edinburgh. As early as 1866 a technological workshop was started in the Museum, and this in recent years has produced some amazingly accurate models, notably one of the Temple bascule bridge, Glasgow, complete with traffic controls, and equipped with a talking label, employing wire recording apparatus. In both World Wars the workshop became a small production unit for national purposes. The collections are housed in six galleries, devoted to power, shipping, mining and metallurgy, navigation and science. Adjacent to the Science Gallery is the Radiation Gallery, in which is a series of exhibits operable by the visitor and showing the properties of a variety of rays.

Dr. C. D. Waterson, assistant keeper in the Department of Geology, refers with natural pride to the historic nature of the collection under his care. They recall the great Wernerian–Huttonian controversy, the exploration of the North-West Passage, and the hobby of Hugh Miller, the stonemason. In common with the other Departments, the return of the material after evacuation for the War gave the opportunity for entirely new display methods in the four galleries at the east end of the top floor. The recent publication of a Catalogue of Fossil Fish recalls the name of Dr. R. H. Traquair, of international repute, who was at one time keeper of the Department of Natural History.

In a closing section, Dr. Allan rightly recalls that centuries are more than end-points, for they are starting-points for a new period of endeavour. With other museums now in the City of Edinburgh, the Royal Scottish Museum still has as its main function the collecting, conservation, display and interpretation of material in art, ethnography, natural history with geology, physical sciences and technology. World-wide exhibits are used where necessary, and Scottish ones where possible.

It only remains to state that the format of this brochure is very attractive. Illustrated with half-tone blocks and plans, it gives a visual impression of the buildings at various stages of their development, and a genealogical diagram portrays clearly the composition of the present staff and their inter-relationships.

It is written and edited in that individualistic, factual but stimulating style which we now associate with the pen of Dr. D. A. Allan, and is not only interesting as a record of achievement in Edinburgh but also recapitulates faithfully much of the history of the museum movement in Great Britain.

THE MUSEUMS ASSOCIATION

THE sixtieth annual conference of the Museums Association was held amidst the capital splendour and beauty of Edinburgh during July 19–23, under the presidency of Sir Leigh Ashton, director of the Victoria and Albert Museum, London.

The conference coincided with the centenary of the Royal Scottish Museum, and members were privileged to attend the ceremony on this historic occasion and share in the greetings offered by distinguished guests. The Minister of State, the Right Hon. the Earl of Home, presided, and felicitations were expressed by those representing the City, the University and museums at home and abroad. Dr. Douglas A. Allan, director, replied and paid a warm tribute to the Ministry of Works and other colleagues who had brought the Royal Scottish Museum to its present high standard of display.

This year no overall theme was selected for the conference; but the individual papers were of a high level, and the discussions were stimulating and of interest both to the professional members and institutional delegates. Sir Leigh Ashton, in his presidential address on "The Functions of Museums", stressed the importance of conservation and enumerated the other functions as assistance given to the scholar, the child and the general public. He paid tribute to the Carnegie United Kingdom Trustees for their welcome help to the museum movement and the influence of their grants for improved presentation, and stressed the importance of imagination in dealing with the educational side of museums.

Mr. Ritchie Calder, in a paper on "Museums: our Wasting Heritage", felt that an artificial culture was replacing real values. He appealed to the museum profession to help in the preservation of our heritage and felt that they could study with advantage much of the publicity methods of the commercial world.

Dr. D. E. Owen (Leeds), speaking on "Making Friends for the Museum", considered that the needs of the museum were different from those of the art gallery. The former required workers both for the acquisition and identification of material, while the latter were in need of patrons to lend, give or buy works of art. A museum of archæology probably required both types. He considered that much help could be given to folk museums by systematic circularization of those in close touch with the countryside.

For the first time in the history of the Association and as an experiment a session was given to sectional meetings. In that devoted to archæology, ethnography and folk-life, Dr. D. B. Harden was chairman, and Mr. R. J. C. Atkinson gave a paper on "A National Index of Archæological Collections". Mr. Atkinson sought the co-operation of museums in the compilation of illustrated indexes of British archæological objects: (1) Inventaria Archæologica of associated groups chiefly of the 2nd millennium B.C.—an international project of which some Belgian and German cards are published; (2) British Association card index of bronze implements, formerly in the British Museum, now at Oxford, in abeyance since 1939; (3) Corpus of Bronze Age pottery, being organized by the Council for British Archæology; and (4) School of Scottish Studies, Edinburgh, neolithic and bronze age indexes. Mr. F. G. G. Carr (National Maritime Museum) and Miss Elspeth M. Gallic (Old Glasgow Museum) then dealt with the difficult problem of the purposeful display of personalia and historical relics. Both speakers stressed the need for proving the authenticity of personalia and historical relics and, if possible, for exhibiting them as part of a well-defined and general pattern. An endeavour must be made to re-create the person to the visitor.

In the section dealing with art and applied art, the president took the chair, and the first discussion was opened by Prof. A. F. Blunt, of the Courtauld Institute of Art, whose subject was "The Teaching of Art History, and the Museum Profession". He described the training in the history of European art provided at the Courtauld Institute. The Institute could not, he stressed, give instruction in the administrative and technical aspects of museum work—this came only with experience and specialized training; but it did provide education of a high standard of great value to entrants to the museum profession.

The other speaker was Miss Helen Gluck, who discussed "The Dilemma of the Painter and Conservator in the Synthetic Age". She showed how, since the commercial introduction of packaged paints, the quality of artist's materials had deteriorated. The situation had become worse since the introduction by the colourmen of synthetic materials. If the paintings of to-day were to survive, the most thorough investigation was required, and a centre, which would make it its business to see that standards were maintained, should be established. Miss Gluck's paper was the subject of lively discussion and the meeting agreed to recommend to the Ministry of Education, as the body responsible for most of the schools of art, that this matter be given serious attention.

The third section, under the chairmanship of Dr. W. E. Swinton, discussed two difficult but important fields for museum treatment. Mr. D. Chilton (Science Museum) defined the essentials of display for meteorology, which is becoming increasingly of public interest, recommending the exhibition of the standard instruments, in use, if possible, and a selection of cloud photographs. Dr. John Burton (medical director of the Central Council for Health Education) stressed the ways in which the local museum could play its part in the hygiene campaign and discussed the kinds of travelling exhibitions which were and could be prepared, and the part that the local medical officer of health could, and probably would, play in co-operation with the museum.

Dr. F. J. North, chairman of the Education Committee, opened a discussion on training problems in the museum profession. After referring to the difficulties of the task and its consequent challenge he said that it should be possible to induce at least one university to establish a department of museology or better still, to create conditions in which the Association could have its own training institution. Subsequent speakers stressed that such a training should be in the nature of a postgraduate diploma course. The training needs of museum curators fall into two categories. First, instruction in some museum subject generally received in a university or equivalent institution, and secondly, the application of that knowledge to the needs of a museum. As matters are at present, training in the latter part can only be given in museums and several trainee-assistant schemes are in operation. Dr. North naturally summarized the diploma scheme of the Museums Association for curators and the more recently instituted technical certificate. Opportunity was taken at the end of the discussion to express the gratitude of the Association for his great services during his eight years chairmanship of the Education Committee and for his pioneer work with regard to the establishment of the diploma and technical certificate.

The hospitality of Edinburgh was extended to members by receptions at the Assembly Rooms, the Royal Scottish Museum and the Scottish United Services Museum, and the Association was honoured by the presence of the Lord Provost and other distinguished citizens at its annual dinner. Tours to Loch Lomond and the Loch Sloy scheme, Haddington and East Lothian and the Border Abbeys closed a stimulating week.

At the annual meeting of the Association, Sir Leigh Ashton was re-elected president, and Mr. E. C. Chubb, director of the Durban Museum and Art Gallery during 1910–51, was elected an honorary fellow. It was decided to hold the next conference at Birmingham during July 4–8, 1955.

THE UPPER ATMOSPHERE

As part of its summer meeting in the University of Edinburgh during July 15–17, the Royal Meteorological Society held a symposium on "The Upper Atmosphere". Dr. O. G. Sutton, president of the Society and director of the Meteorological Office, presided.

The first speaker at the symposium was Sir Edward Appleton, principal of the University, who began by emphasizing the remarkable complexity of the structure of the upper atmosphere and proceeded to give a survey of the present state of our knowledge of the subject, indicating the regions that are the seats of the various phenomena which were to be discussed by subsequent speakers in the symposium. He likened the upper atmosphere to a vast laboratory in which the sun daily actuates a series of experiments at low pressures, in conditions and on a scale which we cannot hope to reproduce experimentally. Solar ultra-violet radiation creates, at different levels, the ozonosphere and the ionosphere by dissociating molecules and by ionizing both atoms and molecules. Further, the gravitational attraction of the sun and moon causes marked atmospheric tides at high evels, and the influence of the earth's magnetic field comes into action as soon as any charged atmospheric particle begins to move. Meteors, sporadic and in showers, produce streaks of ionization which can be observed by eye if clouds are absent and always—even in Manchester—by radio. It may be that fine meteoric dust forms a permanent part of the onosphere.

Sir Edward then discussed some ionospheric problems which he and his research assistants in Edinburgh, Mrs. Pritchard and A. J. Lyon, have recently examined. "If the nature of your occupation prevents you from doing any experiments, it need not prevent you from thinking—thinking about other people's measurements." In the field of geophysics, many people are engaged in making measurements, but he sometimes wondered whether enough people are thinking about what these measurements mean, when they are compared with one another. He and his assistants have been examining measurements of ionization densities in the layers of the ionosphere from a world point of view by using the observations of ionospheric stations operating in different parts of the world.

Examining first the world morphology of the *F*2 layer, they investigated the variation of *fF*2 at noon at the equinoxes with both geographical and geomagnetic latitude and have found the closer fit with the latter. The curve shows a trough in the region of the equator, where *fF*2 is a minimum. When curves are drawn for other times of the day, it is found that in the late evening hours the trough becomes a crest. No such effect appears in similar curves drawn for the *E* and *F*1 layers. This difference between the *F*2 layer and the lower *E* and *F*1 layers is not thought to indicate that the *F*2 layer is caused by electrified corpuscles. They think that ultra-violet radiation, certainly the cause of the *E* and *F*1 layers, is also responsible for the *F*2 layer and that the effect is due to geomagnetic distortion. The movements associated with the diurnal oscillation, tidal or thermal in origin, which these observations disclose, would be subject to strong control by the geomagnetic field at the low densities obtaining at the *F*2 level. But, though theories have been proposed by Martyn, Maeda and Weiss, there is as yet no satisfactory theoretical explanation. The investigation of the *F*2 layer by Sir Edward and his co-workers has further revealed that, during an ionospheric storm, the value of noon *fF*2 is reduced in high latitudes and increased at the equator.

While their examination of the world morphology of the *E* and *F*1 layers has shown no strikingly abnormal effects, even here there are small departures from simple theory. It was well worth while investigating such discrepancies, for there is always the possibility that the investigation may yield a method of measuring the magnitude of the factor which itself causes the discrepancy. In illustration, Sir Edward then considered some features of the *E* layer, and from the continuity equation showed that, in an ionized medium:

$$N = \sqrt{\frac{q_0 \cos\chi}{\alpha}},$$

where N is the ion (or electron) concentration, χ the zenith distance of the sun and α the coefficient of recombination. If q_0 and α are constant, then N is uniquely determined by $\cos\chi$. A curve showing the annual variation of N_E for constant χ may be drawn using experimental data, since χ is the same at noon in winter and in the early morning or late evening in summer. They have found, in fact, that N_E for constant χ has a minimum in June, so that either q_0 or α, or both, varies; conditions are not the same in summer and winter at the same height.

Finally, Sir Edward discussed the methods they are using in their attempt to determine accurate values of the recombination coefficient at low pressures at all times of the day throughout the year and showed how the coefficient may be determined from observation of the time-lag between the maximum of the ionizing process (at noon) and the ionization maximum; values of the order of 10^{-8} and 10^{-9} have been obtained. They have taken the opportunity, afforded by the recent eclipse, of making such measurements at a minimum of solar influence; Mr. Lyon has successfully made radio observations on the ionosphere at Slough, and they are at present engaged on working out the results.

By studying the reflexion of radio waves from the trail of ionized air produced by a meteor, the atmosphere at heights between about 85 and 105 km. may be sampled, simply and at low cost, several hundred times per hour throughout the day. Dr. Ian C. Browne summarized the results obtained by many workers using this method at Jodrell Bank, University of Manchester, since 1946. Measurements of air density and of scale height (about 3×10^{-9} gm. per c.c. and 8·5 km. respectively at 95 km.) may be obtained from observations of the intensities and heights of appearance of meteor echoes, and the atmospheric diffusion coefficient may be calculated from the time of duration of the echoes. In addition, movements of meteor trails of the order of one metre may be detected by using a special technique, so permitting the measurement of wind speed at the height of the trail, for 'meteor winds', in contrast to those obtained by ionospheric methods, are true mass movements of the air. Superimposed on a prevailing wind of about 10 m./sec., there is a semidiurnal component which may have an amplitude of 30 m./sec.; the phase and amplitude of this semidiurnal component show seasonal changes. The winds increase with height, the value of the shear being about 2×10^{-3} per sec., that is, roughly the same as in the troposphere; but there is no change in wind direction with height and no detectable vertical component. Dr. O. G. Sutton asked if Dr. Browne could suggest a mechanism which would account for the maintenance at such great heights of such a regular shear. Dr. Browne was of the opinion that the explanation lies in the temperature distribution at these levels. Dr. T. W. Wormell doubted if the motion of an ionized meteor trail is identical in magnitude and direction with the general air-motion at the same level; he questioned if we could neglect completely the effect of magnetic forces on the moving ions and electrons.

Dr. H. P. Palmer summarized the work at Jodrell Bank on the fluctuations of the power received from the intense sources of radio emission in Cassiopeia and Cygnus. The facts that the fluctuations occur mainly during the night and that the degree of fluctuation varies from night to night, showing a close correlation with the occurrence of 'spread *F*' ionospheric echoes, indicate that the cause is a terrestrial agency, which is thought to be a diffracting screen of irregularities above the maximum of ionization in the *F* region. Small time-differences, which are detectable when records from receivers 2–3 km. apart are compared, are interpreted as evidence of drift motions of the diffracting screen. Drift speeds of 50–300 m./sec. in an east–west direction have recently been determined from approximately vertical observations from three stations. During the months December–April, when these stars transit near midnight, the drift is found to be easterly until 01 hr., U.T., then to reverse sharply and to remain westerly thereafter. When the stars are observed at lower culminations, the line of sight traverses the *F* region in the auroral zone, and fluctuations are then observed at all times, even on magnetically quiet days. Drifts now observed are of greater magnitude and more variable direction, predominantly towards the east during the period 19–21 hr., and towards the north-east or north-west during 21–06 hr.; but it may be that the apparent north–south components arise from vertical motions.

During an investigation into methods of representing the wind field at the 100-mb. pressure-level, it was found that winds observed at this level from British upper-air stations show diurnal and semidiurnal variations. D. H. Johnson, of the Napier Shaw Laboratory, Meteorological Office, Dunstable, gave an account of an analysis he has made of these solar tides in the lower stratosphere. He pointed out that observations at the 100-mb. level are particularly suitable for this study since the lower stratosphere is relatively free from effects that might mask the tides; synoptic variations of wind, for example, are small. Using observations made by radar and radio direction-finding techniques, he computed the deviations of the annual mean south- and west-wind components at three-hourly intervals from the respective overall annual mean wind components and found expressions for the annual mean oscillation of each component by harmonic analysis. He found that the stratospheric oscillation is approximately in phase with the surface wind oscillation derived theoretically by Bartels from Simpson's expression for the semidiurnal variation of surface pressure, a result in accordance with tidal theory. The amplitudes of the south and west wind-component oscillations at the 100-mb. level are 0·67 and 0·51 knots, respectively. The corresponding values derived by Bartels for the surface wind-component oscillations are 0·87 and 0·85 knots, respectively [see also p. 363].

D. H. McIntosh, superintendent of Eskdalemuir Observatory, discussed the possibility of determining winds at ionospheric levels from geomagnetic observations. He outlined the development of theoretical work on the problem of the interpretation of geomagnetic observations since Balfour Stewart suggested in 1882 that the upper atmosphere is highly conducting and that its daily horizontal tidal movement across the vertical component of the earth's field induces currents, the magnetic field of which is observed at the ground as the magnetic daily variation. Schuster, and later Chapman, have developed the theory of the magnetic solar daily variation and of the corresponding lunar effect. While many problems remain unresolved, the theory in its fundamentals has received striking confirmation in several ways, initially by the experimental discovery of the ionosphere and most recently by the discovery by a rocket ascent of a discontinuity of the geomagnetic field at about 100 km., revealing the presence there of a current sheet. So, the dynamo theory of the daily magnetic variation implies that any mass movement of air at ionospheric levels must register in the magnetic records. Wulf has recently examined the problem of determining ionospheric winds in this way, but success has been limited. Vestine, on rather debatable assumptions, has derived wind systems compatible with the annual variation of magnetic disturbance and with the features shown by a particular magnetic storm. Mr. McIntosh wa confident that, with the prospect of obtaining direc measurements of ionospheric winds by means o the newly developed radar-sonde, important progres with this problem is likely in the near future.

A paper by Dr. A. H. Jarrett, of the Universit of St. Andrews, on the possibilities of multilayer coatings for auroral research was read by J. Paton University of Edinburgh, Dr. Jarrett having been detained after his eclipse observations in Sweden longer than anticipated. Examination of the spectrum of auroræ provides a method of estimating temperature at auroral levels; but, because of the low dispersion of auroral spectrographs and of the long exposures necessary with an extended source like the aurora, measurements are difficult and results uncertain. The use of multilayer coatings in place of the usual silver films in the interferometer considerably reduces absorption and so the times of exposure With exposures as short as twenty minutes, Dr. Jarrett has recorded Fabry–Perot fringes from auroræ using the 5577 A. line, by placing the interferometer in front of the *f*/2 Summar 5-cm. focal length camera lens. This preliminary investigation indicates the great possibilities of the use of multilayer coatings in auroral spectroscopy. The United States National Committee for the International Geophysical Year has generously proposed to lend to the British Committee the latest type of auroral spectrograph, working at *f*/0·8 with a dispersion of 25 A./mm. This instrument will be installed at St. Andrews Observatory and will make possible the first British measurements of temperature from auroral spectra. Dr. Jarrett hopes to equip the instrument with a photoelectric scanning arrangement for direct recording.

Brilliant displays of the rare noctilucent clouds have recently been seen from central Scotland, and their height, position and speed have been determined from parallactic photographs. Mr. Paton discussed the importance of observations of these clouds in providing information concerning the physical state of the upper atmosphere at the height of about 80 km. at which they invariably occur. Besides yielding direct measurements of wind, they indicate the existence of a temperature minimum at 80 km. Wind speeds of the order of 50 m./sec. have been measured; Störmer has recorded speeds of more than 100 m./sec., and Jesse of about 300 m./sec. On every occasion when the clouds have been observed from Scotland, this movement has been from the east-north-east. But, since they are made visible by the sunlight scattered by the material of which they are composed, they are observed only on nights when the sun remains close below the horizon—that is, during the summer months in middle latitudes. Presumably they may be present at other times and in other latitudes, but they will not remain sunlit long enough to be observed. Their nature is still in doubt, though their tendency to appear at times of comet and meteor occurrences strongly supports the belief that they consist of meteoric dust. E. G. Bowen has recently pointed out that they appear either on or very near the dates of the daylight meteor streams discovered at Jodrell Bank, but Scottish observations show no such tendency. On one occasion, a portion of the clouds was observed to hange colour from vivid blue to white, suggesting growth of the cloud particles by condensation. When pportunity offers, the new spectrograph at St. Andrews will be employed to investigate such hanges in the spectrum. Finally, slides were shown llustrating a remarkably sudden change from their haracteristically stable structure to quite chaotic hapes that occurred in the early morning of July 25, 1950. Noctilucent clouds have been observed on wenty-two nights since 1939; but this was the only ccasion when turbulence was seen. It may be significant that it was also the only occasion when aurora ccurred simultaneously with the noctilucent clouds.

OBITUARIES

Prof. J. T. Hewitt, O.B.E., F.R.S.

Prof. J. T. Hewitt, while crossing the road near his home at Hurst, Berkshire, on July 9, was knocked down and killed by a motor-car. Although he was eighty-five years of age, he was still active, and his death came as a shock to all who knew him. He was born at Windsor in 1868. After an unconventional schooling, he went to the Hartley Institute (now the University of Southampton) and at sixteen was a student at the Normal School of Science (later the Royal College of Science). At eighteen he was a scholar of St. John's College, Cambridge. He took the Normal School associateship in 1887, and three years later had a first in both parts of the Natural Sciences Tripos and a first in the London Honours B.Sc. Before 1893 was out, he had worked in Heidelberg and in Berlin and had acquired the Ph.D. (Heidelberg) and the D.Sc. (London). He was appointed professor at the People's Palace Technical Schools at Easter 1894, at the age of twenty-five. In the next twenty years, during which the Schools had emerged as a school of the University of London under the title of East London College (now Queen Mary College), he had as students or research students many men who later rose to important academic, governmental or industrial posts. To make a selection is always invidious, but the following names might be mentioned to show the range of interests involved: H. A. Phillips, A. E. Pitt, T. S. Moore, A. E. Dunstan, J. J. Fox, J. Kenner, G. M. Bennett, J. C. Drummond, A. D. Mitchell, T. F. Winmill and W. G. Hiscock.

Hewitt, F. G. Pope and Clarence Smith shared the lecturing at East London; Hewitt gave the intermediate inorganic lectures, which were first class and very well illustrated by experiments, and all the general and honours lectures on inorganic and on physical chemistry. He also attempted to teach his students some mathematics. What was so attractive about Hewitt's lectures was his unconcealed interest in any and every branch of chemistry: in dealing with sodium thiosulphate he could not keep out Bernthsen's methylene blue synthesis, nor Willgerodt and Mascarelli when he was talking about iodine. To him, metallurgical processes, the phase rule, and the determination of accurate atomic weights were all intellectually diverting.

When Hewitt was elected into the Royal Society in 1910, he had an international reputation as an authority on the relation between colour and constitution. He had original views on fluorescence, on the connexion between depth of colour and degree of conjugation, on the constitution of phenthiazine and safranine dyes and on other subjects. Any student in his department who showed ability and enthusiasm was encouraged by Hewitt to get through the routine analytical course as quickly as possible and start some research.

Hewitt wrote an excellent practical book, "Organic Chemical Manipulations", which was unfortunately allowed to get out of print. He invented a process for the quick maturing of whisky and was consulted by the French wine trade. He played an important part in the famous aspirin law case which was lost by the Bayer group.

During the First World War, Hewitt first worked out processes for manufacturing acetic anhydride and for converting benzene–xylene mixtures into toluene. In 1915 he was commissioned as major and went to the Dardanelles, where he was concerned with such diverse matters as water analysis and cylinders of chlorine. Early in 1916 he returned to England and was seconded to the Department of Explosives Supply. He controlled a small factory at Chiswick, with Clarence Smith as a colleague. They dealt first with explosives and later with materials for chemical warfare. Hewitt was a great admirer of his 'chief', Lord Moulton.

Hewitt resigned from his chair at the end of the First World War and in 1919 joined with T. D. Morson, C. S. Roy, Clarence Smith, J. L. Baker and Miss Hewitt (his much beloved sister) to manufacture fine chemicals (quinine ethyl carbonate, quinoline, methylquinolines, benzthiazole, phenylhydrazine, phenylmethylpyrazolone, etc.). This concern gradually decayed for one reason or another, and the Hewitts left it during 1940. Miss Hewitt died in 1943 and thereafter Hewitt lived alone in his cottage at Hurst. He often went to London, to the Chemical Society and to meetings of the University Board of Studies, of which he was an original member (1901). He was one of the first Fellows of Queen Mary College.

Hewitt was a good chemist, a very human personality and (there is no other word) a gentleman. He enjoyed his life and his memories. It was always a pleasure to see him enter a room full of people he knew: that characteristic, half-courtly salutation—the irresistible charm of a man who lived and worked with zest.

E. E. Turner

Prof. H. Frankfort

Henri Frankfort's most outstanding achievement was to have appreciated and by practical example to have taught others to appreciate the value of archæological evidence as a source of human history. His first work—the two volumes of "Studies in the Early Pottery of the Near East"—was not only an original and pioneer comparison of the then available archæological material from predynastic Egypt, prehistoric Mesopotamia and pre-Hellenic Greece, which despite the unpredictable results of many subsequent excavations still provides the accepted guiding lines for the interpretation of Egyptian prehistory. But his "Studies" also eloquently demonstrated how a detailed objective analysis of ceramic techniques, decorative motives and art styles might disclose a history of very much the same sort as that extracted by philologists from orthodox written sources. Frankfort had been trained in the rigorously literary disciplines of the Classics and Egyptology as taught in Holland during the 'twenties. But coming as a postgraduate to University College, London, he fell under the spell of Petrie and imbibed something of his flair for the humanist value of material objects made by man. This combination found original expression in the "Studies" and developed ever more fruitfully in his maturer works: for these remained works of scholarship and interpretation.

Of course, Frankfort was no armchair archæologist—he could never have been a great interpreter had he been that. He gained field experience and added to human knowledge first in directing the Egypt Exploration Society's excavations at Tell el-Amarna and then as field director of the Iraq Expedition of the Oriental Institute of the University of Chicago. The latter post gave not only opportunities of studying the monuments in their proper setting but also of organizing a scientific expedition on a lavish scale. The scientific value of the results obtained at Tell Asmer and Khafaje are essentially the fruits of Frankfort's success as its organizer. For though the expedition did uncover some spectacular objects—hoards of early Sumerian statues, for example—it was the (in Mesopotamia) unprecedented thoroughness and accuracy of the planning, recording and conserving of all finds that have invested the latter with unique historical significance. The publication, still far from complete, had been planned by Frankfort, and his own personal contributions—two volumes devoted to the Sumerian statuary—disclose his sensibility as an art critic and vigour in interpretation.

Still, it is in more comprehensive syntheses, written while he was professor in Chicago and later director of the Warburg Institute in the University of London, that Frankfort's genius found fullest expression. In "Kingship and the Gods", and perhaps still more in the introduction and conclusion (written in collaboration with his first wife) to "An Essay on Speculative Thought in the Ancient Near East", entitled in Great Britain "Before Philosophy" and in the United States. "The Intellectual Adventure of Ancient Man", the reader can see how successfully and naturally an archæologist can assume the role of philosopher and sociologist. V. G. Childe

Dr. Henri Mineur

With the untimely death of Henri Mineur, which occurred after a short illness in Paris on May 7, France has lost one of her most distinguished astronomers, and the Paris Observatory one of the best-known members of its staff.

Henri Mineur was born at Lille in 1899. Entering the army at the age of eighteen, he served for a few months with the Engineers and was demobilized with the rank of second lieutenant. Completing his interrupted education at the École Polytechnique, he graduated in 1921 and took his doctorate in mathematical sciences in 1924. At this stage he decided to make his career in astronomy and accepted a post as assistant astronomer at the Paris Observatory in 1925. Within eleven years of work at the Observatory, he had made such a name for himself that he was appointed, at the age of thirty-seven, as the first director of the newly established Institut d'Astrophysique. Work at the Institute had not got into full swing when, at the outbreak of the Second World War, it was virtually suspended, and he became director of a mathematical laboratory devoted to the solution of defence problems. Enlisting in the Armed Forces in 1940, he was appointed professor at the school of military engineering at Versailles shortly before the fall of France. Demobilized in August 1940, he joined the resistance movement and was dismissed from his official posts by the Vichy Government in 1941. Three years later he was reinstated by the new French Government and served for a short while as captain in an anti-tank unit. Again demobilized in 1946, he turned his energies once more to astronomy, and by the date of his death had re-established the Institut d'Astrophysique as a national postgraduate centre for theoretical and observational attacks on current problems on the frontiers of astrophysics.

Mineur's personal researches covered a wide field in celestial mechanics, pure mathematics, relativity theory and statistics as well as in astronomy. He will perhaps be best remembered for his work on differential galactic rotation, carried out independently of Oort's, but leading by somewhat different methods to substantially the same conclusions, namely, that the Galaxy is rotating about a centre some 8,000 parsecs distant towards galactic longitude 325°, at a rate giving one complete turn in 250 million years in the solar neighbourhood. To his credit are also a number of allied investigations into the equilibrium of open galactic clusters, the time-scale of the universe, and absorption of light in interstellar space. His early training as an observer in the Paris Observatory, and, later, his everyday contact with practising astronomers working in the Institut d'Astrophysique under his general direction, combined to confer on his theoretical work a practical insight which lent increased authority to his results.

M. Mineur was awarded the Damoiseau Prize of the Paris Academy of Sciences in 1944 and the Montyon Prize in 1950. He was created Chevalier of the Légion d'Honneur in 1949. A. Hunter

Dr. Loyd A. Jones

Dr. Loyd A. Jones, who died unexpectedly on May 15 at his home in Rochester, New York, a fortnight after his retirement, was well known for his scientific work in photography. He was born in Nebraska in 1884 and, after graduating in the University of Nebraska, was for two years assistant in the Physics Department of that University, assistant physicist at the U.S. National Bureau of Standards for another two years and then joined the Research Laboratories, Eastman Kodak Company, when they were formed in 1912. He soon became chief physicist and head of the Physics Division.

From then onwards Jones's interests were almost exclusively his work on photography and on scientific committees, and his home and garden. He graduated as an electrical engineer, and something of the qualities of an engineer are to be found in much of his published work. This amounts to about eighty papers. His early work was mainly concerned with the measurement of the properties of photographic materials, the provision of instruments for doing so, and related subjects. The major interest was in sensitometry—the measurement of speed and contrast—and tone-reproduction. The culmination of this work was the paper of 1939, "The Evaluation of Negative Film Speeds in Terms of Print Quality", wherein the criterion of correct exposure of the negative was whether the negative gave as good a print as could be obtained from that negative material whatever the exposure. The quality of the prints was estimated by purely visual judgment, without reference to any physical measurements. The process sounds, and indeed was, laborious; but something of the kind is inevitable, and in Loyd A. Jones's hands it led to a physical measurement which correlated well with the observed speed. This way of measuring speed was adopted by the American Standards Association and the British Standards Institution. The same characteristic approach is to be found in his later papers, on graininess and granularity, and on sharpness, wherein the main effort is directed to the discovery of a purely physical measurement which correlates well with some visual estimate.

Loyd A. Jones served on many scientific bodies, notably on the Colorimetry Committee of the Optical Society of America and the sectional committee on photography of the American Standards Association, for many years. Besides the recognition which he received from scientific and photographic societies in the United States, the Royal Photographic Society of Great Britain awarded him its Progress Medal, the Hurter and Driffield Medal and an honorary fellowship. He leaves a wife and many friends to regret his death so soon after retirement. E. R. Davies

---

Mr. Hugh Griffiths

The chemical engineering profession has lost a doughty fighter in Hugh Griffiths, who died on June 26, 1954. He was born at Middlesbrough on July 28, 1891, and a very strong influence on his career was his contact there with A. F. van der Heyden, who laid the foundation of his love for mathematics. He took his A.R.C.Sc. in chemistry and was for the most part of his life in consulting practice. His command of the German language and his contacts on the Continent proved most valuable in this connexion.

In 1945 he was elected president of the Institution of Chemical Engineers. As a biography is contained in the *Transactions* for that year, it is now opportune to try to assess his outstanding contribution to the profession. This was undoubtedly his advocacy of the use of the 'Home Paper' as a part qualification for associate membership. He came into the chemical engineering profession as a young man with the practical heritage of the Victorian period behind him. First and foremost with him was the essential engineering background—the need for a practical estimate of the magnitude of the problem and the sizes involved. It was his mathematical and scientific training which then enabled him to apply fundamental conceptions to rule-of-thumb methods, and to develop processes in a manner not dreamt of by his forbears.

His philosophy in supporting the use of the 'Home Paper' for examination purposes was the realization that, if a student is faced with a problem such as, for example, the design of a plant required for the manufacture of 10 tons a day of mono-nitrotoluene, it brings out all that is latent within him and automatically poses to him all the problems which a chemical engineer has to face to be successful. His fierce advocacy of the use of this method of training did sometimes bring him into conflict with his colleagues, as he was always afraid that modifications might result in a lowering of his high standards.

It was in keeping with Griffiths's love of his profession and its heritage that his last public appearance was at Mr. Norman Swindin's lecture in Manchester on the life of that grand old man and founder of chemical engineering, George E. Davis. It was then only too apparent to his colleagues that his life was on the ebb tide. In him they have lost a good friend, and the profession has lost a notable servant.

M. B. Donald

NEWS and VIEWS

Agricultural Physiology at Cambridge: Dr. John Hammond, F.R.S.

Dr. John Hammond, who on September 30 retires from his post as reader in agricultural physiology in the University of Cambridge and his honorary directorship of the Agricultural Research Council Unit of Animal Reproduction, has brought an immense amount of prestige to British agricultural science. While his contribution to fundamental research is widely appreciated, it will be as the prophet—in the proper sense of the word—of the physiology of reproduction that his name will be honoured. Son of a Norfolk farmer and nephew of a veterinary surgeon, he absorbed as a student the teaching of the late Dr. F. H. A. Marshall on the pure physiology of reproduction. The significance of his life's work is that, at a time when animal production was under the influence of pedigree breeders and the auction mart, on one hand, and the pathological outlook of the veterinary profession on the other, he brought to its development a more positive scientific approach. The essence of his teaching was the extent to which production could be increased by studying the normal physiology of farm animals and not merely by removing the adverse effects of disease and abnormal physiology. Further, and this may yet be his greatest monument, Dr. Hammond has enthused a large and influential band of disciples, not only within the British Commonwealth but also throughout the world, to initiate research themselves and apply the newer knowledge to the farming industry. Among a wide range of subjects on which he has worked must be mentioned the reproduction and milk production of the cow, which provided the basis of the artificial insemination movement in Britain, and his study of the effect of nutrition and environment on the growth and conformation of sheep and pigs. If the study of animal husbandry ever becomes a profession independent of either agriculture or veterinary science, it will be largely due to the pioneer work and inspiration of John Hammond.

Registrar of Trade Marks in India: Dr. S. Venkateswaran

Dr. S. Venkateswaran, deputy registrar of trade marks, India, has been appointed as registrar of trade marks in succession to K. S. Shavaksha, who has recently retired. Dr. Venkateswaran, who is a D.Sc. of the University of Madras and a law graduate of the University of Calcutta, was assistant chemist at the Agricultural Research Institute, Pusa, and at the Government Test House, Alipore, during 1922–30, and has worked under Sir C. V. Raman, publishing several research papers on light scattering and Raman effect. He was elected a Fellow of the Indian Academy of Sciences in 1934. Dr. Venkateswaran joined the Indian Patent Office in 1930 as an examiner of patents and was successively special officer for trade marks (1940), assistant registrar (1940–44) and deputy registrar (1944 to date). He has been prominently associated with the enactment of the trade mark legislation in India, and his most important book, "The Law of Trade and Merchandise Marks" (1937), besides being a legal text-book, presents a complete case for trade mark legislation in India. The new Patents Bill is now before the Indian Parliament, and there is a proposal to combine the Patent Office and the Trade Marks Office again, as was the case before their separation in 1943 owing to certain administrative reasons. Although it is now more than fifteen years since trade mark legislation was enacted in India, India has not yet joined the International Convention for Industrial Property and there is no reciprocal arrangement for trade marks between India and other members of the British Commonwealth. It is understood that the Government of India is now actively considering the question of taking early steps to join the International Convention.

Charles P. Daly Medal of the American Geographical Society: Dr. J. K. Wright

DR. JOHN KIRTLAND WRIGHT, geographer–historian, has been awarded the Charles P. Daly Medal of the American Geographical Society for his outstanding contributions to the field of geography through his administrative services, writing and research. Dr. Wright joined the staff of the American Geographical Society in 1920 as librarian, and served in that capacity until 1938, when he became director; in 1949 he resigned his post as director, and since then has devoted his time to research and writing. He was president of the Association of American Geographers in 1946, and during 1949–52 was chairman of the Commission (of the International Geographical Union) on the International Map of the World. The Daly Medal was established in 1902 in accordance with the will of Judge Charles P. Daly, eminent New York jurist and president of the American Geographical Society during 1864–99, and is awarded from time to time (thirty-seven times during the past fifty-one years) for "valuable or distinguished services or labors".

British Abstracts of Medical Sciences

As far back as 1915 the Physiological Society decided that an abstracting service for physiology was essential. It would be no over-statement to-day to say that such a service is absolutely vital for further progress. So voluminous has the literature become that no medical scientist can keep abreast of the publications in his field. With this in mind, a Committee representing the Anatomical, Biochemical, Endocrinological, Nutrition, Pharmacological and Physiological Societies decided that the cessation of *British Abstracts AIII* was unfortunate and that every effort should be made to continue this valuable abstracting service. As a token of goodwill and to ensure that a new journal would be launched, a sum of approximately £3,000 was subscribed by some of the above Societies. This enabled a start to be made, and the January 1954 issue of *British Abstracts of Medical Sciences* was published on January 20. Of the twelve monthly issues, seven have already appeared. The December issue will be an author and subject index, the work for which is already well in hand.

The *ad hoc* Committee of the above Societies decided that for success and security of the enterprise some form of legal entity was essential. This has been done, and the organization responsible for the continuance of *British Abstracts of Medical Sciences* is Biological and Medical Abstracts, Ltd., with registered offices at the Lister Institute. The Council of Management is made up of four representatives of the Physiological Society, two of the Biochemical Society and one each of the Anatomical, Endocrinological, Nutrition and Pharmacological Societies. The editorial office is also at the Lister Institute, where a full-time staff are engaged in the day-to-day running of the journal. In addition, there are twelve honorary specialist editors, chosen by the supporting societies, who supervise abstracting in their respective fields. Indicative abstracts of all significant papers in anatomy, biochemistry, endocrinology, experimental biology, experimental medicine, microbiology, odontology, pathology, pharmacology and physiology are prepared from more than six hundred journals published throughout the world by a large group of helpful abstractors. Every endeavour is made to publish these abstracts within six months of the appearance of the journal. Realizing that abstracts are of little value unless they (and the necessary indexes) are promptly produced, the Council hopes to reduce the time of publication still further. The composition and printing of abstracts is costly, so the price of £10 per annum, including postage, is made possible by the devoted labours of men whose aim is the advancement of their science.

Protection against Betatron and Synchrotron Radiations

THE recommendations made by the National Committee on Radiation Protection, which are published in the United States as National Bureau of Standards Handbooks, serve as guides for protection against general hazards of radiation sources. The development in recent years of high-energy electron accelerators, some of which are now being built commercially, and their widespread use in hospitals and elsewhere make it necessary to provide the operators of these accelerators with a handbook warning them of the potential radiation hazards both to themselves, to patients in hospital and to the public, and of the appropriate precautions that should accordingly be taken. Handbook 55, "Protection against Betatron–Synchrotron Radiations up to 100 Million Electron Volts" (pp. 52. Washington, D.C.: Superintendent of Documents, 1954; 25 cents), prepared by Subcommittee 5 of the National Committee on Radiation Protection, deals with high-energy electron accelerators of the betatron and synchrotron types. The hazards resulting from the various radiations produced by the sources are considered, together with those due to certain associated effects, such as noise, electricity and ozone production. Since the experimental data relating to protection requirements for these sources are far from complete, and thus measurement techniques and systems of units are not well established, the handbook includes an initial section in which definitions of the various technical terms used are clearly stated and listed, and nine appendixes in which detailed discussions are given of proposed units and measurement procedures. The following are dealt with in particular: the choice of the units for radiation intensity (watt/cm.^{2}) and for dose (erg/gm.), thus avoiding the use of the roentgen; the choice of a radiation-intensity secondary standard; a 5-cm. thick 'Lucite' cover for the sensitive element of a survey instrument; and the recommendation for high-energy installations of the standard personnel-monitoring procedures at present in use for radiations of less than 2 MeV.

United States Unclassified Material on Atomic Energy

The United States Atomic Energy Commission has named the Stanford Research Institute, California, as one of three national industrial information depositories of unclassified information concerning developments in the field of atomic energy, the other two depositories being the Atomic Industrial Forum of New York and the John Crerar Library of Chicago. The Stanford Research Institute will serve particularly the western States and Hawaii and Alaska, by maintaining the collection and providing library, reference, photocopy and literature-search services to public interests. It has recently received an initial complement of materials consisting of seven hundred reports of industrial interest selected from 9,500 'basic science' reports filed with the Atomic Energy Commission, as well as a set of reproductions of drawings for a 'swimming pool' reactor, all the back issues of *Nuclear Science Abstracts* and sets of bibliographies of selected reports of value to industry. Mr. William A. Casler has been appointed to take charge of the depository. In December 1952 the Institute opened a Radiation Engineering Laboratory for industrial research with radioactive materials, the source of cobalt-60 provided to the Laboratory by the Atomic Energy Commission being the largest released for such use at the time. The previous year the Institute published results of a study sponsored by the Commission on "Industrial Uses of Radioactive Fission Products".

Financial Estimates for the Department of Scientific and Industrial Research

In reply to further questions in the House of Commons on July 27, the Parliamentary Secretary to the Ministry of Works, Mr. J. R. Bevins, stated that the published estimate of £6·25 million for the Department of Scientific and Industrial Research for the present financial year represented an increase of £578,000 over last year (not £71,440 as stated in *Nature*, August 7, p. 251), of which £230,000 was part of the projected expansion by £900,000 over five years. The gross expenditure had increased from £5·8 million in 1952 to £7 million in the present year. The non-industrial staff, 3,108 on July 1, 1954, compared with 2,500 in 1949, would be increased to 3,900 in 1959, when the general level of activity would be 95 per cent of that projected in the expansion plans of 1947–48. At present the cost of the research on sulphate-reducing bacteria, on which twelve people were engaged at the Chemical Research Laboratory, was about £13,000 a year, and that of the work on corrosion of buried pipes, on which six people were engaged, about £6,000 a year. Studies of marine bacteriology, smoke curing, hygiene of fish handling and freezing at the Torry Research Station were at present held up on account of insufficient staff and inadequate buildings. On July 30 Mr. Bevins also stated that during the period April 1946–July 1954 the Department had made grants totalling £1,621,700 to the universities for the construction of high-energy particle-accelerating machines for nuclear physics research, and that grants of £747,200 had so far been made for running costs during the period August 1952–July 1957.

Survey of Scientific Journals in the United States

The report of a survey of the operations and finances of scientific journals in the United States has been published in a recent issue of *Science* (119, 357; 1954). The survey, by R. Tumbleson and Helen L. Brownson, is based on the 110 replies received to 205 questionnaires distributed by the National Science Foundation to a selected list of periodicals, with circulations ranging from five hundred to sixty thousand or more, seeking information regarding circulation, volume of original research papers published, papers awaiting publication, sources of revenue and expense items. No data are included for periodicals of the American Medical Association or the American Chemical Society; but about 71 per cent of the replies related to the journals of scientific societies, and in this group 58 per cent of subscribers were members; for periodicals with a circulation of four thousand or less, this figure was 50 per cent; for more than four thousand, 68 per cent. This group of periodicals published on the average nine hundred pages of original research material, or about 70 per cent of all papers submitted; many of the others were rejected because they were submitted to the wrong periodical. Seventy of these periodicals had a delay for accepted articles of less than six months; twenty-five, a delay of six months to a year, and five of a year or more, the average being 5·3 months for those publishing five hundred pages or less a year and 1·9 months for those publishing more than two thousand pages; for periodicals publishing articles averaging four pages or less, the delay was 5·6 months compared with 2·1 months for those in which the average article was twenty pages or more. Subscriptions and society contribution in lieu of subscription represented 67·2 per cent of the income for periodicals with a circulation of less than a thousand, 69·8 per cent for those with a circulation of 1,000–7,999, and 45·2 per cent for those with more than 8,000; advertising revenue was 0·7 per cent, 14·2 per cent and 51·5 per cent, respectively. Most editors disliked the idea of a direct subsidy from any sources, including the Federal Government, and many believed that additional income should be obtained from society membership or advertising. Attention was directed to difficulties, expense and delay caused by bad writing and presentation.

Lancaster Royal Grammar School: *The New Biologian*

The third issue of *The New Biologian*, the journal of the Natural History Society of Lancaster Royal Grammar School, has recently been published (June 1954). In the report of the Society's activities, by P. Brindley, it is recorded that a three-day exhibition was held in the biology laboratories, and several lectures given and films exhibited. P. F. Williams and P. E. Walker describe the bird-life of a hundred-acre field, where they concentrated mainly on the two heronries. G. J. Beckett gives an illustrated account of fern-collecting in northern England: it is unfortunate that in the caption of one illustration the word 'spleenwort' is spelt in three different ways. It is a pity that in this article, and indeed in all the other articles, the generic and specific names are printed in the same Roman type as the rest of the text. Other articles recording some excellent field-work include hover-flies by R. Underwood, the birds of Arkholme by A. N. Gardner, the molluscs of Port Erin (I.O.M.) by P. Brindley, and British mountain scenery by F. D. Stell. Other articles include the meteorological summary for June 1953–May 1954 by J. I. Sharp, a description of making prints of leaves, etc., on photographic paper by A. M. Till, trout by G. Smith, collecting bees, wasps, etc., by T. H. Pennington, some observations of *Amoeba* by P. F. Williams, and a short description of giant tadpoles by G. H. Briggs.

Corrosion Technology

Starting in March this year, *Corrosion Technology* was published as a supplement to *Chemical and Process Engineering*, and from June it has appeared as a separate monthly journal, published by Leonard Hill, Ltd., of London (1, No. 4; June 1954. 40s. a year, or 100s. for 3 years). There are now, therefore, two monthly journals devoted to the subject of corrosion, the other being *Corrosion Prevention and Control* (see *Nature*, May 8, p. 853). *Corrosion Technology* carries three columns to a page, 12 in. by 9 in. The journal includes many useful items of news concerning developments in methods of preventing corrosion, in addition to the technical articles by various authorities. These include one on "Corrosion in relation to Welding", by Dr. U. R. Evans, of Cambridge; others deal with the corrosion resistance of welded stainless steel, paint versus corrosion, cathodic protection, corrosion research at the Chemical Research Laboratory, Teddington, rubber linings to protect plant in a new bromine factory, prevention of corrosion by water in oil refineries, non-metallic materials of construction for handling radioactive wastes, radioactive testing of rust preventives, corrosion of aluminium cable sheathing, cutting fluids and corrosion, and corrosion and tablet machinery. The variety of the topics reflects the wide range of the subject of corrosion. The journal is well produced, and it serves a useful purpose in providing corrosion workers, as well as engineers and others concerned with protection against corrosion, with up-to-date news and reviews of recent developments in the subject.

Periodicals in South Asia on the Physical and Biological Sciences

With the assistance of the United Nations Educational, Scientific and Cultural Organization, the Indian Library Association has now published Vol. 1, covering the physical and biological sciences, of a "Union Catalogue of Learned Periodical Publications in South Asia" (pp. 390. Delhi: Indian Library Association; London: George Blunt and Sons. Rs. 25, 9 dollars or 60s.; 1953). It is essentially the work of the Department of Library Science of the University of Delhi, and its publication represents the partial fulfilment of an aspiration of Dr. S. R. Ranganathan, the principal editor, twenty-five years ago; all the collaborators are past or present students of his. The Catalogue covers 175 libraries in India and 74 in Indonesia, Malaya, Burma and Ceylon. It consists of a Systematic Catalogue, arranged according to the Colon Classification, and indicating the status or subject of specialization of the library, as well as the holdings, and of an alphabetical index, in which title words of periodicals are given in heavy type. There is also a schedule of sub-classes of the Colon Classification covered and a key to library numbers. The Catalogue should prove of great assistance to research workers in South Asia.

Society for General Microbiology

The Society for General Microbiology has recently undergone some reorganization and has established a central office at the Institute of Biology, Tavistock House South, Tavistock Square, London, W.C.1, to which inquiries regarding applications for membership and payment of subscriptions should in future be directed. Other matters should be communicated to the appropriate officer of the Society, and inquiries about the *Journal of General Microbiology* to the Cambridge University Press. At the last annual general meeting a new set of rules of the Society was passed, which now govern its activities. The nineteenth general meeting is to be held in the University of Reading during September 14–16 and is to include a discussion meeting on the "Principles of Microbial Classification". New officers of the Society are as follows: *General Secretary*, Prof. K. E. Cooper (Department of Preventive Medicine, University of Bristol); and *New Members of Committee*, Dr. B. W. Lacey, Miss June Lascelles and Dr. P. Tate. The remaining officers are: *President*, Mr. H. J. Bunker; *Treasurer*, Prof. R. Lovell; *Editors of the Journal*, Prof. B. C. J. G. Knight and Mr. A. F. B. Standfast; and *Meetings Secretary*, Dr. E. F. Gale (Department of Biochemistry, University of Cambridge).

Biology of the Trout

Regular observations have been made by the Scottish Home Office Brown Trout Research Laboratory, near Pitlochry in Perthshire, on freshwater biology in that area. Under the title of "Spawning Migration, Reproduction and Young Stages of Loch Trout (*Salmo trutta* L.)", Mr. T. A. Stuart has now recorded the results of research on the behaviour, reproduction and development of trout in their natural spawning grounds in three lochs, Lochan an Daim, Dunalastair Reservoir and Loch Moraig (Freshwater and Salmon Fisheries Research, No. 5. Pp. 40. Edinburgh: H.M.S.O., 1953; 7s. 6d. net). While the gonads appear to ripen at approximately the same time each year, the dates of spawning are influenced by the temperature. Prior to the spawning migration, a shoaling habit is formed and the trout congregate at the entrance to the streams chosen for spawning. Shoaling was only in evidence when the temperature of the loch water dropped to about 9° C. The main spawning run took place when the temperature of the streams dropped for the first time to 6–7° C. and was lower than that of the loch. In his observations on the trout's behaviour in forming the redd, Mr. Stuart has made the notable discovery that, apart from selection of gravel of suitable size, appreciation of the current conditions plays a most important part. He has shown that towards the tail-ends of pools, where the gravel slopes upwards, there is a point at which the current flows downwards through the gravel and keeps it free of silt. The trout are evidently aware of this and, after testing movements, come to rest there, probably aided by the slight suction from below. At such points the redds are made. Further interesting observations are recorded on the reactions of the alevins to light, the ventilation of redds by the movement of their pectoral fins, and the re-entering of the gravel by the post-larvæ. This paper constitutes the most objective account of the early life of the trout yet available.

Nigerian Vegetation

IN a short memoir, under the above title, R. W. J. Keay has presented an outline account of the main vegetational types of the very considerable and varied Nigerian territory. His aim is to interest and instruct agriculturists, foresters, naturalists, educationists and others in the botany and geography of Nigeria, no general account of the vegetation of this region having hitherto been available. In this extensive region the vegetation ranges from wet rain forest to very dry thorn savannah, few single African countries presenting such a range of vegetational types. The author rightly reminds his readers that only a relatively narrow coastal belt is covered with rich rain forest, the greater part of the hinterland consisting of savannah. The latter is clothed in tall grasses during the rainy season but becomes bare and open during the dry season, when the grass is burnt. The thorn savannah occupies only a small area in the extreme north, with the Sahara desert over the frontier still farther to the north. The forest regions are described under the headings of mangrove forest and coastal vegetation, freshwater swamp communities, and the lowland rain forest zone; the savannah regions are discussed under four different zones; and an account is given of the montane vegetation with special reference to the very interesting floristic region of Cameroon Mountain (13,350 ft.). The results of various ecological studies have been worked into this, the second edition of this work. Some useful and interesting vegetation profile diagrams and a comprehensive, if as yet provisional, map of the principal vegetation zones are appended to the text. The memoir is published by the Government Printer, Lagos, Nigeria, and can also be obtained from the Crown Agents, 4 Millbank, London, S.W.1.

Pathogens of the Sugar Maple

A FURTHER paper in the extended series of studies in forest pathology in Canada is contributed by V. J. Nordin on the causes of decay in the sugar maple (*Acer saccharum*) in Ontario (*Canad. J. Bot.*, 32, 221; 1954). Decay results in appreciable losses in volume of sound wood. Seventy-four per cent of 606 sample trees had some measure of decay. Twenty-eight fungi were found to be associated with decay in living trees. The most important of these are *Armillaria mellea* (Vahl ex. Fr.) Quél., *Polyporus glomeratus* Peck, *Ustulina vulgaris* Tul., *Fomes connatus* (Weinm.) Gill., *Hydnum septentrionale* Fr., *Corticium vellereum* Ell. and Crag., *Pholiota spectabilis* Fr., and *Fomes igniarius* (L. ex. Fr.) Gill. Several species previously unreported in the literature were found to be associated with decay in sugar maple in Ontario. *Armillaria mellea* is the most serious butt-decay fungus and *P. glomeratus* is the most important trunk-rotting species. Frost cracks are the most important site of entry for fungi. Various discolorations occur in sugar maple. The average extent of decay in living trees is estimated according to the occurrence of sporophores of *F. connatus*, *F. igniarius*, *H. septentrionale* and *U. vulgaris*. The incidence and volume of decay increased progressively with age and diameter. One hundred and nine species of Basidiomycetes are tabulated as occurring on living and dead sugar maple in Ontario. This paper is illustrated by a large number of plates.

Aboriginal Rock-paintings in Australia

UNTIL quite recently there had been little evidence of aboriginal occupation in New South Wales. Investigations by W. H. Kinsela in the area immediately south of Sydney and extending throughout the Illawarra coast and tablelands have shown that, besides the well-known kitchen-middens, there are several groups of rock-paintings (*Aust. Mus. Mag.*, 11, No. 4). In the Avon River valley, for example, one group of paintings contained many figures drawn in black, the dominant one being a woman with exaggerated breasts. Some others, including a wombat, were in red. Among the charcoal pictures is the realistic side-view of a human, in silhouette, with a genuine attempt to put natural shape into body and limbs. The paintings throughout the whole of this 'new' area of the South Coast tablelands are typical of the species, style and technique seen elsewhere in eastern New South Wales. There is, however, a marked absence of the mass-patterns of stencilled-hand paintings which are seen so frequently in Hawkesbury Sandstone areas north from the South Coast. The majority of the paintings visited are fairly faint, and difficult to reproduce by photography.

Colonial Development Corporation: Report for 1953

THE annual report and accounts of the Colonial Development Corporation for the year ended December 31, 1953 (pp. 50. London: H.M.S.O., 1954; 2s. net), records the initiation of five new projects, the abandonment of seven projects and the termination of the East African ramie investigation, the Kenya fish farms and the Vitingini lead investigation, leaving fifty continuing projects and investigations. Capital sanctioned increased from £39,400,000 in 1952 to £43,512,000 in 1953, mainly for productive projects, of which agriculture, animal products, forestry and minerals now account for 54 per cent, or 56 per cent of the £25,349,000 employed, and several agricultural/forestry projects now in early phases of development will eventually need large expenditures to bring them to completion. A further substantial reduction in head-office administration costs was effected during the year, the United Kingdom staff being reduced from 248 to 183 and regional offices staff from 114 to 106, but further reduction is unlikely at the present scale of operations. For most projects the local labour is fairly efficient, though in some areas it is low, due mainly to poor physique, malnutrition, debilitating diseases and lack of education. In agricultural research a panel of agricultural scientists established in London in March 1953, with Sir Charles Darwin as chairman, has been of great help, and the Corporation's experiences and problems are made known to those who allocate Colonial Development and Welfare funds for agricultural research, affording an indication of priorities in this field.

National Museum of Wales: Report for 1952–53

THE forty-sixth annual report of the National Museum of Wales, Cardiff, covering the year 1952–53 (pp. 63; from the Museum, Cardiff; 1953), is the first to appear in the new format. The smaller size is more interesting and handier and is to be commended as a type of production to be copied. It is stated that unfortunately there is no possibility of a licence being obtained for the extension to the west wing of the Museum, though, on the other hand, it is possible that one may be issued for a smaller building to serve as a beginning of a museum block at the Welsh Folk Museum, St. Fagans. This would permit the removal to St. Fagans of folk-life material and lead to a reorganization of the first-floor galleries at Cardiff. The freeing of the circular gallery for temporary exhibitions would be a welcome action. Work in the geological gallery has been devoted towards improving the appearance but not the essential range and purpose of the exhibits. At the Welsh Folk Museum the chief activity has been again the re-erection of buildings. The Montgomeryshire house is now thatched and wattled, and the stone house from Gower is nearing completion. An upland farmhouse from Dyffryn Claerwen, Radnorshire, has been accepted and will provide the Museum with its first complete unit of stable, cowhouse and dwelling.

National Research Council of Canada: Awards for 1954–55

The National Research Council of Canada has granted 236 scholarships for 1954–55, totalling in value 283,200 dollars. These scholarships include 75 bursaries worth 800 dollars each, 103 studentships worth 1,100 dollars each and 21 fellowships worth 1,400 dollars each, all of which are to be held in Canada. Special scholarships awarded for study abroad include twenty awards worth 1,900 dollars each, which will be held in the following countries: ten in the United States, eight in the United Kingdom, one in France and one in Sweden. Seventeen overseas postdoctorate fellowships worth 2,500 dollars each have been granted for work in the following countries: twelve in the United Kingdom, two in Sweden, one in Denmark, one in France and one in the Netherlands.

Colonial Service: Recent Appointments

The following appointments have been made in the Colonial Service: D. W. Malcolm (principal assistant secretary, Tanganyika), secretary for agriculture and natural resources, Tanganyika; A. F. Mackenzie (deputy director of agriculture, Sierra Leone), director of agriculture, British Guiana; F. E. Hughes (deputy chief conservator of forests, Gold Coast), chief conservator of forests, Gold Coast; I. G. John (assistant director, Malayan Meteorological Service), director Malayan Meteorological Service; N. S. Sandeman (assistant game warden, Uganda), game ranger, Kenya; A. J. Vincent, assistant conservator of forests, Federation of Malaya; A. Crosbie, veterinary officer, Northern Rhodesia; Miss E. R. Blydenstein, meteorologist, East Africa High Commission; J. O. Goss, agricultural officer, Nigeria; B. G. Hoare, agricultural officer, Gold Coast; A. R. Longhurst, scientific officer, West African Fisheries Research Institute, Sierra Leone; W. G. Owen, geographer, Hydrological Survey Department, Uganda; J. F. Truswell, geologist, Nigeria.

Announcements

The Atomic Energy Authority announces that Mr. W. R. J. Cook, chief of the Royal Naval Scientific Service since 1950 (see *Nature*, 166, 135; 1950), has been released from his present post to take up that of deputy director of the Atomic Weapons Research Establishment, Aldermaston, the director of which is Sir William Penney.

The Lister Medal for 1954, which is given in recognition of distinguished contributions to surgical science, has been awarded to Mr. Victor Ewings Negus, consulting surgeon to the Ear, Nose and Throat Department of King's College Hospital, London, in recognition of his services to the advancement of knowledge in the surgery of the nose and throat by means of his researches into the comparative anatomy and physiology of the larynx and para-nasal sinuses. This is the eleventh occasion of the award, which is made by a committee representative of the Royal Society, the Royal College of Surgeons of England, the Royal College of Surgeons in Ireland, the University of Edinburgh and the University of Glasgow.

The College of Physicians of Philadelphia has awarded the Alvarenga Prize for 1954 to Dr. DeWitt Stetten, jun., associate director in charge of research, National Institute of Arthritis and Metabolic Diseases, National Institutes of Health, Bethesda, Maryland, for his outstanding contributions to knowledge of metabolic diseases. The Alvarenga Prize was established by the will of Pedro Francisco DaCosta Alvarenga, of Lisbon, an associate fellow of the College, to be awarded annually on the anniversary of his death on July 14, 1883.

The Faraday Society will be holding a general discussion on "Coagulation and Flocculation" in the Department of Chemistry, University of Sheffield, during September 15–17, under the chairmanship of Prof. R. G. W. Norrish, president of the Society. The twenty-nine papers to be presented will be divided into three groups, with introductory addresses for each group by the following: classical coagulation, Prof. J. T. G. Overbeek (Utrecht); coacervation, Dr. A. S. C. Lawrence (Sheffield); and biological systems, Dr. J. R. Marrack (Cambridge). Advance proofs of all the papers will be available about the end of this month. Applications for accommodation (to be made not later than September 6) and all other inquiries should be sent to the Secretary of the Faraday Society, 6 Gray's Inn Square, Gray's Inn, London, W.C.1.

The Oil and Colour Chemists' Association will be holding a symposium on "Rheology and Settlement of Pigmented Systems" on September 23 in the Chemistry Theatre of University College, Gower Street, London, W.C.1. In the morning Prof. Stacey G. Ward will give a lecture on properties of well-defined suspensions of solids in liquids, and Mr. J. Pryce-Jones on the rheological state of a suspension as a criterion for the study of the flow and settlement of paints. The afternoon session will be devoted to a discussion on these two papers. The symposium will be open to non-members on application to the general secretary of the Association, R. H. Hamblin, Memorial Hall, Farringdon Street, London, E.C.4, from whom further information can be obtained.

The ninth Annual Calorimetry Conference in the United States will be held in the General Electric Research Laboratory, The Knolls, Schenectady, New York, during September 17–18, under the chairmanship of Dr. E. J. Prosen (National Bureau of Standards, Washington, D.C.). The conference is open to all, without registration fees. Further information can be obtained from Dr. Warren DeSorbo, General Electric Company, Metallurgy Research Department, Research Laboratory, P.O. Box 1088, Schenectady, New York.

INSTITUTION OF ELECTRONICS EXHIBITION IN MANCHESTER

THE ninth Annual Exhibition of Electronic Devices, organized by the North-West Branch of the Institution of Electronics, was held in the Manchester College of Technology during July 14–20. The Exhibition was as large and efficiently organized as any of its predecessors, and was as deservedly popular. It included, in addition to exhibits in the commercial and research sections, a programme of general and specialized lectures, and a number of illustrative film shows. For an affair of this size—some forty exhibitors were represented—a detailed review cannot be given; the writer must restrict his attention to a few of the features which he found most interesting.

The commercial section was impressive chiefly for its evidence of steady progress in the development of known techniques. Applications of television were prominent, and there were on view no fewer than three industrial closed-circuit television channels (by Pye, Philips Electrical, and J. Langham Thompson). Low-inertia integrating motors were shown by Electro Methods, Ltd.; these motors have practically straight voltage-speed characteristics, and are used for time integration of minute voltages. The Saunders–Roe exhibit included some interesting and, incidentally, very handsome strain gauges. These are made of metal foil etched into suitable strain-sensitive patterns, and mounted on an epoxy resin lacquer backing. They are more robust than conventional wire gauges, and permit a higher input current without compromising stability. Part of the large Mullard exhibit consisted of a formidable array of ultrasonic devices. Among them was an ultrasonic drill press, designed for the drilling or machining, by the action of an abrasive slurry between the vibrating tool and the work, of such intractable materials as glass. Equipment for the ultrasonic cleaning of fragile or inaccessible objects, and an ultrasonic soldering-iron capable of dealing with aluminium, were also demonstrated.

Prominent in the research section were the stands of the British Rayon Research Association. Among the recently developed instruments on display was an ingeniously simple autocorrelogram computer, used for the separation of periodic from random irregularities in yarns. The same exhibit included a demonstration of equipment used in flash photolysis. In this technique an intensely bright flash of short duration is used for irradiating a specimen, and after a selected interval of 20 μsec. or more, a second, less bright, but shorter, flash is used to record the absorption spectrum of the specimen. In this way the presence and decay of short-lived products of irradiation can be studied.

The Institute of Cancer Research exhibited ultrasonic echo-locating equipment, used for the examination of brain structure. When the equipment is in use, a quartz transducer in acoustic contact with the head emits a narrow, pulsed beam of ultrasound. Any echoes incident on the transducer are transmitted as pulses through amplifier and display circuits, and appear on an oscillograph screen. The position of the pulse on the screen gives a measure of the distance of the source of the echo from the transducer. At present, observations are being compared with what is known of the 'normal' brain, with the view of the possible identification of abnormal structures. In view of the drastic effects of ultrasonic vibrations, as demonstrated in the Mullard exhibit, it should be mentioned that the power output of the transducer is only 30 μW. Since the vibrations suffer considerable attenuation on entering and leaving the skull, it is clear that high sensitivity is required of the amplifiers.

A portable twelve-channel toposcope, designed as an aid to the increasingly important subject of electroencephalography, was exhibited by the Burden Neurological Institute. The complete study of the simultaneous electrical activity associated with a number of points on the head, for a significant period, is bound to be almost prohibitively time-consuming. The purpose of the toposcope is to restrict severely the type of information to be studied, and to present it in a rational manner. The equipment can be set for a desired frequency, or alternatively it can be made to set itself servo-mechanically for the predominant signal frequency of any selected channel, and in this condition it is sensitive only to that frequency or its harmonics. The display panel consists of a number of cathode-ray tubes, and each of these indicates for one of the channels (that is, for one of the selected points on the head) which, if any, of the harmonics of the driving signal is present, and what its relative phase is. A larger version of the equipment has been in use at the Burden Institute for the past two years, and has proved to be of particular value in research on the functional anatomy of the brain.

The Exhibition as a whole has proved to be of the highest interest to very many visitors, and due credit must be paid to the exhibitors and organizers alike.

BRITISH CAST IRON RESEARCH ASSOCIATION

OPEN DAY

THE British Cast Iron Research Association, Birmingham, held an open day on July 7 for representatives of member-firms, some three hundred of whom attended, being welcomed by the president, Sir Frederick Scopes. The next day some hundred and fifty attended from other research associations, government laboratories, trade associations, technical institutions, universities, technical colleges and schools.

The extensions last reported (*Nature*, 170, 153; 1952) have been fully brought into use, except for the new melting shop, which has yet to be equipped, but which in the meantime is being used for work on foundry atmospheres. The Association has been negotiating with the Department of Scientific and Industrial Research with respect to arrangements for its new grant period, during which it is hoped a further stage of expansion will be reached.

A feature which attracted considerable interest was a display of art castings in moulded iron, involving very advanced skills in pattern-making and moulding. The importance of maintaining these skills is indicated by the adoption in recent years of such medieval methods as the lost wax process for producing jet engine parts which have to be cast to very accurate tolerances, and to their final dimensions, since they are frequently too hard to machine.

The experimental work on view included the study of the mechanism of blister formation on porcelain-enamelled cast iron, the gas originating the blister defect being removed during heating in a stream of argon and measured by an infra-red gas analyser. The application of strain gauge techniques to measure stresses set up in actual castings in service was illustrated. An important section related to work on white and chilled cast irons as used in the roll-making industry and referred to the effect of various conditions, composition and temperature, affecting the depth of chill.

Considerable advance was shown in the section on moulding and core sands tested at the elevated temperatures to which they are subjected in practice by induction heating, and the mechanism of the formation of defects due to sand failure was shown by a working model. A train for the production and casting of shell moulds of resin-bonded silica sand, about 5 mm. thick, was demonstrated, together with a newly devised arrangement for testing the material itself. Other work on moulding sands related to their effect on the shrinkage characteristics of the cast metal and on surface finish. The pore size of sand aggregates has been shown to affect heat transfer, mould permeability, gas flow during pouring and metal penetration.

The vacuum fusion method has been developed to yield quantitative information on the gases present in cast iron, especially oxygen and nitrogen, and the vacuum heating principle is used for the determination of hydrogen. Gamma-radiography was demonstrated for determining unsoundness in castings. The use of cathodic protection for cast iron pipe lines in aggressive soils and for propellers in sea-water was shown. In the analytical block a variety of demonstrations was in progress on chemical methods of examination and on spectrographic analysis, the latter including foundry slags.

Although no formal programme on the problem of brittle fracture has existed, since this problem mainly concerns the steels, a useful result has emerged from parallel studies of two aspects of the properties of ferritic nodular iron castings—properties at low temperatures and properties under impact. It appears that the ferritic nodular irons are better suited to resist the phenomenon of brittle fracture than many steels. Transition temperatures for ordinary ferritic nodular iron may be as low as −50° C., and with specially chosen raw materials this could be reduced to −100° C.

The work of the Foundry Atmospheres Team has made considerable progress. The control of dust on practically every type of rotating wheel used for cleaning and grinding castings, many of which are common to a wide range of other industries, has been established, and some devices are in commercial production. A systematic study of the behaviour of dust-laden air streams at the knock-out, where castings are normally separated from their sand envelopes, has been begun. A satisfactory design of wet spark arrester for cupola furnaces has been evolved and will assist in dealing with external atmospheric pollution.

J. G. PEARCE

BRITISH COLONIAL TERRITORIES

REPORT FOR 1953–54

If the proposals of the White Paper entitled "Re-organization of the Colonial Service" (Colonial No. 306. London: H.M.S.O., 1954; *4d.* net) are implemented, the recently published report on "The Colonial Territories 1953–54"* may be the last survey to appear under that title. It is proposed to constitute from October 1, 1954, an Oversea Civil Service which will include all those officers now in the Colonial Service who have been selected for their present posts by the Secretary of State for the Colonies whether or not the territory in which they are serving attains self-government. Should the territory attain self-government, their conditions of service and pension rights will be safeguarded by formal agreement between the Government in the United Kingdom and the Government of the territory. When the new Service is in being, any offer of appointment will include a clear statement whether it carries membership of the Oversea Civil Service or whether the officer's contractual relationship will be solely with the territorial Government. Officers in either category will be expected to regard themselves as being in all respects responsible to the territorial governments under which they are serving.

The new form of Service is intended to safeguard the interests of existing officers as well as to overcome political difficulties or prejudices which are more fully indicated in the review of constitutional and administrative developments in "The Colonial Territories 1953–54" report than in introductory paragraphs of the White Paper. It is also intended to encourage qualified men and women to continue to come forward in a spirit of confidence, enthusiasm and partnership and to assist the social, economic and political progress of the overseas governments and peoples. The present decisions are not intended to exclude the constitution of a Commonwealth service or an overseas service directly employed by the British Government, but the Government has not yet reached any conclusions on the complicated administrative and constitutional, as well as financial, problems involved in such proposals.

Apart from providing a very convenient conspectus of the political, economic and financial, and social developments in the Colonial territories for prospective candidates for appointments in the Colonial Service, whether scientific or not, "The Colonial Territories 1953–54" is also of interest to the man of science as providing the background against which progress in Colonial research, for developments in education, in health and welfare, and in communications and industry in these territories are appropriately considered. In particular, the surveys of constitutional and of economic and financial developments should facilitate both responsible criticism of particular developments and a general understanding of the extent to which economic and social developments, as well as the application of the results of the research at present in progress, depend on education.

In all branches of education the expansion of facilities continued during 1953–54, and special stress is laid on the increased provision for training teachers, alike in Malaya, Singapore, and Hong Kong, in the larger West African territories (where in view of the rapid expansion in primary education determined efforts are being made to maintain standards of efficiency), in Kenya and in Tanganyika. In Uganda, where the output of trained teachers is to be increased to about 1,150 by 1956, the British Government has allocated £8 million from the African Development Fund over the period 1953–60 to implement the recommendations of the de Bunsen Committee as well as £2 million for the development of technical education. In Northern Rhodesia, the establishment of a unified African teaching service was finally approved, and £1,250,000 was allocated from Colonial Development and Welfare Funds for the establishment of Rhodesia University College, the foundation stone of which was laid at Salisbury by the Queen Mother on July 13, 1953. During the academic year 1953–54 there were 3,639 full-time students at the three universities and four university colleges, and steps were taken during the year to strengthen the intimate relations between the Colonial institutions and other universities, particularly through a Colonial Development and Welfare grant to facilitate secondment of staff to the Colonial universities and colleges, and the extension of the Commonwealth Interchange Scheme to cover visits to and from Colonial institutions. Educational exchange was also assisted under the Fulbright Agreement, nineteen men and women from the Colonial territories receiving travel grants under this scheme for study or research in the United States, and thirteen American lecturers, research scholars or students being selected for attachment to Colonial universities. Of nearly eight thousand Colonial students in the United Kingdom and the Irish Republic at the end of 1953, 1,965 were scholarship holders, and the report again pays tribute to the work of the British Council in finding accommodation for these students. In higher technical education, the Nigerian College of Arts, Science and Technology had its first major entry of students. A Commission was appointed to make recommendations for the development of Fourah Bay College in relation to the educational requirements of Sierra Leone at all levels, and Major-General C. Bullard took up his post as first principal of the Royal Technical College of East Africa, Nairobi.

---

* Colonial Office. The Colonial Territories 1953–54. (Cmd. 9169.) Pp. xii+196. (London: H.M. Stationery Office, 1954.) 6s. net.

No widespread epidemic occurred during 1953, and available figures point to an almost universal fall in mortality-rates and a general rise in the expectation of life. Human trypanosomiasis is now fairly well under control in Africa but only as a result of constant vigilance and the maintenance of active control measures. In Fiji, where filariasis is very prevalent, an attempt was made at control by mass administration of 'Hetrazan' in conjunction with a campaign against the mosquito vector. Yaws is fast disappearing from closely settled areas, and the scientific application of insecticides eliminated relapsing fever from the Somaliland Protectorate. Tuberculosis, however, remains a grave problem, and while treatment with modern drugs and antibiotics has proved very effective, present facilities for diagnosis, treatment and control are inadequate. Spectacular progress has been made in the control of malaria and leprosy; but much research is still needed to elucidate the provocative factors in the epidemiology of kala azar, of which three thousand cases were reported in Kenya up to the end of 1953.

The review states that the flow of recruits to the Colonial Medical Departments is insufficient, and although an increasing number of doctors of local origin are becoming available for service in their own territories, recruits from the United Kingdom are urgently needed, particularly for Nigeria and the Pacific. On December 31, there were 230 scholarship holders and 595 other students from Colonial territories in the medical schools of the United Kingdom and the Irish Republic as well as 97 students of dentistry, most of whom were expected to return to work in their own countries, while considerable numbers of doctors are also being trained in the Universities of Malaya and Hong Kong and the University Colleges of the West Indies and Ibadan. Training schemes for medical auxiliaries remain an urgent priority, and although the number of Colonial student nurses in training in the United Kingdom continues to increase rapidly, recruitment of nursing sisters from the United Kingdom and Commonwealth countries was difficult and new appointments did not keep pace with resignations. The scheme for the provision of a panel of medical visitors to the African territories has proved a success, and it is hoped that the scheme will be continued and a similar scheme introduced in other areas.

Expenditure on development and welfare schemes and on research was again approximately £14 million. In addition, a loan of £2,390,000 for the development of the East African parts of Mombasa and Tanga was made from sterling Counterpart funds by the United States Government. Fifty-nine research schemes, estimated to cost £741,000, were approved during the year, thirty-one new appointments were made on Colonial Research Service terms and seven research studentships were awarded. The progress in research, which is summarized in the chapter on "Research and Surveys", is to be covered more fully in the subsequent report "Colonial Research 1953–54", and it will suffice here to note that the West African Government has agreed to set up a Permanent Standing Advisory Committee for Agricultural Research, and that the establishment of a Regional Research Centre in the West Indies is receiving attention. Most of the Colonial governments have now agreed to the establishment of a Colonial Road Research Station, though only a few to the establishment of research funds in the Colonial territories. Arrangements are now being made to establish a Colonial Road Research Section at the Road Research Laboratory, Harmondsworth, and also the proposed Advisory Committee. The West African Regional Standing Advisory Committee for Medical Research has been converted into a Council for Medical Research, and administrative measures are in hand for a similar organization in East Africa. The establishment of a new entomological research station in Benin Province of Nigeria will permit an intensive study for the first time of those species of tsetse which occur in the high forest belt. At the West Africa Rice Research Station in Sierra Leone good progress was made with investigations on the development of mangrove swamps for rice-growing. In Nigeria the sealing-off policy in combating swollen-shoot disease of cacao did not prove completely effective, and further research on the behaviour of the virus is being carried out at a sub-station of the West African Cacao Research Institute opened at Ibadan. Successful research on the use of copper sprays has led to a large-scale campaign in Nigeria for the control of black-pod disease of cacao. Arrangements are being made to open a sub-station of the West African Institute for Oil Palm Research in Sierra Leone; but although the Institute continued its work on the establishment, nutrition, breeding and diseases of oil palms, lack of staff made its Plant Physiology Division inactive. Thirty-one new appointments were made to the Colonial Research Service and seven research studentships were awarded to train candidates for research appointments.

Recruitment of field staff for geodetic and topographic surveys kept just ahead of transfers and resignations; but thirty-two new appointments to the cartographic staff were offset by thirty-seven resignations dismissals or call-up to national service. Nevertheless, very satisfactory progress was made with geodetic surveys. The overseas scientific staff of the Colonial Geological Surveys increased from 190 to 197 during 1953, and although there were still some twenty vacant posts, satisfactory progress continued in all branches, including geological mapping, the investigation of mineral resources, and in the geological aspects of engineering and water-supply projects.

Besides the expenditure from Colonial Development and Welfare Funds, the United Kingdom contributed approximately £20,200,000 from the Vote for Colonial Services during 1953–54, and the present report sounds a warning note in respect of finance. While public expenditure has continued to rise, as well as the total of Colonial government general and development reserves in London, financial prospects in many territories are not encouraging. Revenues in Nigeria and the Gold Coast continued to rise sharply as a result of the steady increase in cocoa prices, but in Malaya revenue was 20 per cent lower than in 1952. Tanganyika's revenue fell by more than 10 per cent, mainly as a result of the fall in sisal prices, while those of North Borneo and Sarawak also fell. Generally, the picture has been one of a flattening-out of the curve of revenue increases.

While capital goods have been easier to obtain, though not cheaper, and capital expenditure and development are at present limited rather by shortages of administrative and technical staff, it is clear from this report that developments in future may no longer be able to count on an almost automatic increase in revenue. More governments are likely to be faced with deficiencies in the near future if the present trends of revenue and expenditure continue, and the report emphasizes that the increase in government commitments and costs since 1939, particularly in the maintenance of the expanded social services, makes any decline in revenue a cause of alarm.

HYDRAULICS RESEARCH STATION

REPORT FOR 1953

THE report for 1953 of the Hydraulics Research Board* describes work done during the year at the Hydraulics Research Station, Wallingford, and also in the field. It covers a range of activities, including investigations, mainly by models, into the design of harbours, jetties and other coastal works, beach surveys, special investigations arising from the east coast floods of January 31–February 1, 1953, and a preliminary study, based on charts and maps, of drainage and reclamation works in the Wash.

Two parties from the Research Station visited a number of places on the east coast of England from Margate to Scarborough during the four days February 3–6, their main objects being to examine the damage to sea defences and beaches and to take photographs, before repair works were started or the return to normal conditions had obliterated the effects of the storm on the beaches. Experiments carried out on a pilot model of the Thames Estuary, at the request of the Waverley Committee, showed that if the freshwater flow had been at its maximum value of 20,000 cusec. at Teddington Weir, instead of the low value of 2,600 cusec. actually existing at the time, the high-water level in London would have been increased by 9 in., a result in good agreement with previous estimates.

An example of work carried out for other countries of the British Commonwealth is that done on two models of Lyttleton Harbour, New Zealand. The object of the investigation is to assess the merits of various proposed designs of harbour extensions from the point of view of protection from waves, susceptibility to ranging and the amount of dredging required. The tests carried out so far have been designed to reproduce the existing conditions. On the larger model, that of the inner harbour, the distribution of wave heights throughout the harbour has been plotted for several wave periods, and the response at a given point as the period of the waves is varied has also been examined experimentally. Another overseas project was the design of a weir block to prevent waves passing up the discharge channel for cooling water at the thermal power station recently constructed at Dekhelia in Cyprus.

The facilities for research on models will be increased when the first stage of the main hall of the Station, which will have a floor area of 300 ft. by 200 ft., has been completed; work on this was proceeding during 1953, and it is hoped that it will be ready for use early in 1955. One of the models to be housed in it will be a large model of the Severn Estuary, on which the effects of the proposed Severn Barrage can be examined. In the meantime, preliminary experiments are being made on a pilot model, which is largely a replica of that built by Prof. A. H. Gibson.

An investigation of a somewhat different kind has been started on land reclamation and drainage in the Wash, at the request of the Ministry of Agriculture and Fisheries. While training works, constructed at various times during the past hundred and fifty years to improve the outfalls of the four principal rivers, have had the desired subsidiary effect of increasing the area available for reclamation, they have been less successful in achieving their primary object, because of deterioration of the estuaries to seaward of them. By treating the Wash as a whole, it is hoped to be able to design extensions to the training works which will improve the outfalls and also result in an additional fifty thousand acres of saltings becoming available for reclamation.

While most of the work described was undertaken in connexion with specific engineering projects, an item of more fundamental research was that carried out in the wave tank on the effect of a vertical wall on a beach in front of it. After the beach had become stable under the action of waves and tides, the wall was inserted in a position between the high-water mark and the highest point reached by the swash.

---

* Department of Scientific and Industrial Research. Report of the Hydraulics Research Board with the Report of the Director of Hydraulics Research for the Year 1953. Pp. vi+58+8 plates+4 maps. (London: H.M.S.O., 1954.) 7s. 6d. net.

When the wave and tidal action was continued, the level of the sand against the wall fell until, after thirty-three tides, it was approximately at low-water level.

During coastal surveys in the Southwold and Christchurch areas, observations were made with drift indicators which showed that swell, accompanied by gentle or offshore winds, set up a drift which was shoreward near the bed and seaward at the surface. With steep waves accompanied by onshore winds, however, it appears that these directions are reversed. Among the new instruments developed is a miniature current meter for measuring the flow in models at velocities down to 0·25 in./sec.; this consists of a small plastic propeller the revolutions of which are timed electronically, making use of the change in conductance produced by the passage of each blade of the propeller between two electrodes.

K. F. BOWDEN

DRYING OF BIOLOGICAL CULTURES

JUDGED by replies to a questionnaire sent out in 1948, only twenty-five of ninety-five laboratories in the United Kingdom then used some form of drying technique for the maintenance of their stock cultures. Since that time the method has been applied much more extensively, and last September the British Commonwealth Collections of Micro-organisms arranged a discussion of the principles and methods of applying freeze-drying to culture maintenance to which home and visiting scientists were asked to contribute. The proceedings of the meeting have now been published*. In the event the discussion centred more on methods than on principles, about which we seem to be woefully ignorant.

Many methods are available for drying cultures on a small scale; but the only one readily applicable to the production of a large number of ampoules are those developed by R. I. N. Greaves from his experience of drying blood products. The designer's view is that the biologist is unnecessarily exacting, and to meet his requirements apparatus has become unduly expensive. Plant has to be designed to satisfy the biologist on three major points: the temperature of drying, the speed of drying and the rate of freezing; each of these is profoundly affected by small changes in technique, such as by increasing slightly the volume of material in each ampoule. The biologists are not prepared to accept the engineer's view that further developments lie with the bacteriologist; the best possible machine for the job has not yet been produced.

Of biological factors affecting survival of micro-organisms after drying, P. J. Fisher's work shows that the culture age is important, old cultures surviving better than young: it was suggested that autolytic breakdown products, such as deoxyribonucleoprotein, might have a protective action. The suspending fluid affects survival in at least two ways: during freezing, crystallization of salts may be injurious; but the main killing effect of the freeze-drying process takes place when the water is first taken off under vacuum. The ultimate survival-rate is improved by the addition of 7·5 per cent glucose to the suspending fluid, and, as survival also seems to depend on the residual moisture content of the dried product, it has been argued that glucose automatically controls the residual moisture. Unfortunately, moisture determination is technically difficult, but apparatus recently developed may so simplify the procedure that it will become part of the drying routine. With apparatus of this type it has been shown that, when solutions containing glucose are dried, moisture removal continues for three months. After sealing, there is an increase in vapour pressure in the ampoule which can be shown by a high-frequency discharge tester producing a glow inside the ampoule and not in the glass wall, and it is possible that there is a redistribution of moisture from the slow-releasing glucose to the protein which had been rapidly desiccated. In vessels closed with rubber stoppers there may be a re-hydration from diffusion of moisture through the rubber.

Freeze-drying may have some effect on the metabolism of surviving cells, and strains used for the production of antibiotics have been found to lose the ability to produce the dehydrogenase enzyme notatin. However, the experience of most of those taking part in the discussion was that, for bacteria and fungi, freeze-drying is the best method of keeping in stable form the metabolic activities which determine the biochemical reactions, antigenic patterns and the virulence of pathogens.

THE FUTURE FOR TECHNOLOGICAL STUDIES

IN his Messel Memorial Lecture to the Society of Chemical Industry at Liverpool on July 14 (*Chem. and Indust.*, 940; July 31, 1954), Lord Cherwell suggested that recognition by the large chemical firms in Great Britain of the fact that fundamental research is essential to progress is the main reason why the British chemical industry has been able to develop so rapidly and to overcome its handicaps. No other industry in the country has shown so much foresight and understanding of the vital importance of fundamental investigation which at first sight might seem to have no relation with practical applications. First among the industry's handicaps is the lack of facilities in Britain for higher technological education. In spite of their efficiency and merit, the existing university departments of chemical engineering cannot meet all our requirements. In industrial atomic power the efficiency of the chemical recovery determines whether or not the plant is an economic proposition, and many more like Sir Christopher Hinton and his team are needed to tackle such novel and difficult problems. It is not possible in Britain, said Lord Cherwell, for a young man to study at university institutions the first principles of technology and the disciplines on which it is based before deciding which particular technology to follow, and it is wrong to confine teaching of the highest branches of technology to ordinary universities. Lord Cherwell argued again for a technological university—with some three thousand students and fifty or more professors—such as no existing university could accommodate without distorting its balance of studies.

The main obstacle to such a proposal, he urged, is intellectual snobbery regarding technology which still pervades Britain, although it takes just as much brains to become a first-class technologist as to become a first-class lawyer, and probably more. Since this battle which he has fought for the past twenty years has been unsuccessful, Lord Cherwell found the reason for his being awarded the Messel Memorial Medal in his early work on physical chemistry, dating from that with Prof. W. Nernst in Berlin more than forty years ago. Nernst was then mainly concerned with the heat theorem known as the third law of thermodynamics, and Lord Cherwell showed briefly how a suggestion by Einstein regarding the derivation of Planck's formula led to the discovery that action could only be transferred in units of a minute but finite size. The processes for synthesizing ammonia or petroleum depend, in fact, on the reinstatement in a space–time description of the conjugated dynamical co-ordinate.

The world is now entering an epoch of nuclear chemistry, continued Lord Cherwell, about which our knowledge is as rudimentary as that of chemistry itself a hundred and fifty years ago. No one can say whether the building up or the breaking down of nuclei will play the predominant part in generations to come. Even in classical chemistry there are problems of which we have only scratched the surface, such as the extraction of the uranium and the plutonium after irradiation from the rods full of lethal fission products and the disposal of these intensely active products. Whether we can utilize the energy potentially available has yet to be seen, and meanwhile man for the first time has it in his power to destroy all life on this planet. The question is whether he will be able to avoid some such form of universal suicide, and it is a sad reflexion on our political achievements and mental processes that, despite the universal wish for peace, man has not been able so to arrange his affairs as to avoid war and the continuing threat of war.

STANDARDS AND LEVELS OF LIVING

A COMMITTEE of United Nations experts has concluded that most of the short-cut methods for comparing levels of living in different countries are unsuitable and sometimes misleading. For example, both national income *per capita* and real wages have serious defects as indexes of levels of living*.

To present useful comparison the committee recommends a pluralistic approach by analysis of various 'components' of living which are amenable to quantitative treatment and reflect internationally accepted values or aims. The twelve components listed by the experts are: health, including demographic conditions; food and nutrition; education, including literacy and skills; conditions of work; employment situation; aggregate consumption and savings; transportation; housing, including household facilities; clothing; recreation and entertainment; social security; and human freedoms.

In addition, the report includes a series of more specific statistical indicators that should be used as a guide in measuring the various components; these indicators are chosen with the view of availability of information. In view of deficiencies of data in many countries, however, the report gives a minimum list of 'priority indicators'; it indicates how they may be obtained and adds another set of indicators to illustrate lines of further improvement.

Members of the committee recognized that an international analysis of levels of living, in terms of the components and indicators they proposed, would nevertheless fall short of giving a complete and balanced picture of the total situation. They stressed the importance of the use of descriptive materials and background information, particularly in the form of social and cultural analyses. A more direct and comprehensive assessment may be attainable by 'family living surveys' carried out by the use of sampling methods and designed to ensure international comparability.

The committee was appointed by the Secretary-General of the United Nations, jointly with the International Labour Organization and the United Nations Educational, Scientific and Cultural Organization. Members came from six different countries and represented various disciplines of social sciences and statistics. They were Prof. Raymond Firth, professor of anthropology in the London School of Economics and Political Science; Prof. Philip M. Hauser, professor of sociology in the University of Chicago; Mr. Erland v. Hofsten, chief of the Statistical Section, Social Welfare Board of Sweden; Father Louis Joseph Lebret, editor of *Economie et Humanisme*, France; Mr. O. Alexander Moraes, acting secretary-general of the Inter-American Statistical Institute of the Organization of American States; and Mr. V. K. R. V. Rao, director of the Delhi School of Economics, University of Delhi.

MANAGEMENT COSTS

THE costs of managing industrial firms have traditionally been regarded as an incidental class of expenditure. These costs have been rising rapidly and, to-day, administrative costs have become a major expense in the operation of industrial firms. By 1948, for example, of every hundred production workers in British industrial firms, twenty were administrative employees; in 1907 the number was only eight.

Information collected by Seymour Melman shows that, in Great Britain at least, there has been no correlation between increases in administrative overheads and the growth of productivity. (*Manchester Guardian* "Survey of Industry, Trade and Finance", 1954). In the United States, on the other hand, output per worker man-hour rose by 232 per cent from 1899 to 1947 while the administrative overhead ratio increased by over 40 per cent. In Great Britain the output per worker man-hour increased by 73 per cent from 1907 to 1948 while the ratio of administrative overheads grew by 133 per cent. It has been assumed that the growth in the cost of managing necessarily yields some economy in production; there is no evidence of any relationship of this kind.

Various reasons have been put forward to explain the growth of administrative costs in view of increasing mechanization and systematization. Melman suggests that increasing costs are due to the development of new managerial functions. Industrial management has chosen solutions to its problems which also involve the extension of formal managerial controls over ever-widening areas. The extension of managerial controls is the common feature of the growth of new functions in industrial management, including sales, accounting, cost accounting, personnel and industrial relations, as well as the addition of staff specialists trained in economics, psychology and similar disciplines. This growth in administrative staffs represents more than the trend of a business cost. It is also a social cost owing to its bearing on the effective productivity of industrial man-hours. The growth of administrative overhead will be stopped or reversed only when its development becomes the source of pressing problems to one or more of the important groups closely concerned with industrial production: that is, management, labour or government. Only then will there be a search for alternative ways of industrial decision-making which would simplify and reduce the costs of managing.

EXPERIMENTS ON THE CAUSE OF DORSIVENTRALITY IN LEAVES

In a recent article, R. and M. Snow[1] reported experiments bearing on the cause of dorsiventrality in leaves, the results of which differed from those which I had obtained[2]. If, in my experiments, the position at which a leaf primordium was about to arise at the shoot apex of potato was isolated from the remainder of the apical meristem by a single vertical incision, the leaf which arose on the isolated panel of tissue was radially symmetrical[2], and I concluded that dorsiventrality of the leaves is induced by the activity of the apical meristem of the shoot.

It is this conclusion that the Snows question. They have repeated this experiment using potato shoots, and in only one instance, when the apex suffered from loss of turgidity after the incision was made, did the isolated leaf develop as a radial structure; in all other shoots the leaf formed was dorsiventral. However, they state that in *Epilobium hirsutum*, but not in other species, radially symmetrical leaves arose when the central part of P_1, the youngest leaf primordium, or the presumptive position of I_1, the next leaf to arise, was confined at its sides by two vertical incisions which left them continuous with the stem apex towards the centre. (In potato shoots dorsiventral leaves emerge between such pairs of incisions.) R. and M. Snow[1] suggest that a radial leaf may develop, in *Epilobium* at least, from an area which is in some way weakened, or is insufficiently large to give rise to a dorsiventral leaf. If this conclusion is valid then intrinsic factors, in the leaf primordium itself, would be operative in determining the symmetry of the leaf.

The following experiments, performed on potato apices, are relevant in that they permit a distinction between the two hypotheses of intrinsic and extrinsic determination of leaf dorsiventrality. If the centre of the apical meristem is punctured with a fine needle new leaves continue to emerge on the apical flanks. In some shoots up to eight new leaves have emerged in normal phyllotactic sequence while the puncture remained at the summit of the meristem. In every case the new leaves so formed were dorsiventral, and of normal size. In other experiments, a newly emergent P_1 primordium, or the presumptive position of I_1, together with a small adaxially situated panel of meristematic tissue not used in leaf formation, was isolated by a vertical incision from the centre of the apical meristem[3]. The isolated P_1 and I_1 primordia developed as dorsiventral leaves.

The position of the isolating incision in relation to the presumptive position of the leaf is critical. When the incision is close to the presumptive position of the leaf, the leaf is radially symmetrical[2]; when farther away, as in the experiments just described, the leaf is dorsiventral. Thus, if dorsiventrality is induced in the leaf primordium by the shoot apical meristem, the induction can be carried out by small areas of the meristem, approximately one-sixth of the meristem being sufficient[3]. This may explain the variation between results obtained by R. and M. Snow and myself. It seems probable that the incision by which they isolated the I_1 presumptive position was not close to the I_1 position, but was sufficiently far from it to include on the isolated panel some small portion of the apical meristem of the shoot, for they state[1] that in their experiments "radial leaves developed from small unoccupied areas of tissue that were left over somewhere between the isolated I_1 leaves and the stem". From the experiments described above it would be expected that I_1 would be dorsiventral when so isolated.

That the hypothesis of apical control of leaf dorsiventrality is reasonable is shown in the following series of experiments. When the I_1 presumptive position in potato is isolated from the remainder of the apical meristem, I_1 develops as a centric organ[2]. On the isolated panel, and lying on the cathodic (P_1) side of the I_1 presumptive position, is a small group of cells which were part of the apical meristem. These cells undergo differentiation and do not produce a new shoot meristem when so isolated, apparently being unable to compete successfully with the larger bulk of the terminal part of the meristem[3,4]. If, however, the emergent leaf primordia P_1 and P_2, and the terminal part of the apical meristem of the shoot are excised, leaving only the isolated I_1 panel, then the meristematic cells on the panel lateral to the I_1 presumptive position regenerate a new shoot meristem, and when I_1 emerges it does so as a dorsiventral leaf, orientated towards this new meristem, and deflected by approximately 90° from its expected orientation in an intact apex. If the excision of P_1, P_2, and the terminal part of the shoot meristem is delayed for 24–48 hours, by which time I_1 is just beginning to emerge as a centric organ, and the meristematic tissues lateral to it have begun to differentiate, no shoot meristem is regenerated on the panel, and I_1 develops as an enlarged centric organ encroaching over most of the panel surface. These enlarged centric I_1 primordia have a well-developed and extensive solenostelic vascular cylinder, and may be taller than dorsiventral leaves of the same age. They do not, therefore, appear to be the result of nutritional depletion in the leaf-forming area. It thus seems that factors extrinsic to the leaf primordium are effective in determining leaf dorsiventrality and, for dorsiventrality to occur, the leaf-forming area must be in direct continuity distally with cells of the apical meristem.

This explanation does not in its present form account for the emergence of radial leaves between two lateral incisions in *Epilobium*; however, the apical control of leaf dorsiventrality in the fern *Dryopteris aristata* has been experimentally demonstrated by Wardlaw[5] and more recently by Cutter[6], who has shown that even young emergent leaves in this species may be caused to develop as radially symmetrical buds bearing leaf primordia when they are isolated by an incision from the apical meristem. Centric organs in potato have always been determinate in growth; nevertheless the radial symmetry of such isolated organs in members of two widely different taxonomic groups suggests an essential homology of underlying processes, involving participation of the apical meristem, in the determination of leaf dorsiventrality.

These experiments were carried out in the Department of Cryptogamic Botany, University of Manchester, and I am indebted to Prof. C. W. Wardlaw for his guidance and encouragement.

[3] Sussex, I. M., *Nature*, 170, 755 (1952).

[4] Sussex, I. M., *Nature*, 171, 224 (1953).

[5] Wardlaw, C. W., *Growth* (supplement), 9, 93 (1949). Cutter, E. G., *Nature*, 173, 440 (1954).

Since Dr. Sussex now considers that his views are supported by experiments in which the summit of the apex or growing-point was destroyed and dorsiventral leaves continued to be found on the apical cone below, it appears that he now thinks that the dorsiventrality of the leaves is induced in potato shoots not by the summit of the apex, but by apical tissue between the summit and the zone where leaves are determined. He seeks to explain the dorsiventral I_1 and I_2 leaves which we obtained when we isolated the presumptive areas of these leaves by supposing that our cuts were too close to the summit of the apex, so that they included some apical tissue on the isolated piece above the presumptive leaf area.

But in isolating I_1 in potato shoots we regularly placed our cuts *farther* from the summit of the apex, and closer to the I_1 than did Dr. Sussex according to his description. For he has stated[1] that his cuts extended from an edge of P_2 to an edge of P_1, as also his diagram indicates, whereas our cuts extended from the same edge of P_2, or from only just within it, to a certain point on the periphery of the apex well short of the edge of P_1. We isolated I_2 in a similar manner. So pieces such as Dr. Sussex isolated would be rather larger than ours, and would also be not entirely at the correct angular position, in our potato apices at least. For the radii through the centres of such pieces would be considerably cathodic from the normal centre of I_1—considerably closer, that is, to P_1. This is clear from the fact that P_1 and I_1 are successive leaves, and successive leaves, as we find, do not make contact in potatoes. Moreover, five of the dorsiventral leaves which developed from our isolated pieces had no axillary bud on the isolated piece, and two others had only a very small axillary bud on it, if any. This makes it unlikely that the cuts isolating these pieces were even as close to the growing point as the upper boundary of the isolated presumptive area; and it is even less likely that these cuts included on the isolated piece any tissue still closer to the summit of the apex, as Dr. Sussex suggests. (It should be explained that when the presumptive area of a leaf is isolated, its axillary bud develops either on the isolated piece or not at all: it does not develop on the axis[2].)

Also, even if in some of the other isolations a little surplus apical tissue may possibly have been included with the isolated I_1 or I_2, it seems unlikely that such tissue could induce dorsiventrality in these leaves by any physiological process. For any surplus isolated apical tissue which does not develop into an organ becomes disorganized and ceases growing. Only in a very few of the isolated pieces did we find tiny radial leaves which had apparently been formed from surplus apical tissue, and these were rather to one side of the dorsiventral isolated leaf and its axillary bud, not directly above them.

However, Dr. Sussex also states that among his own isolations of I_1 those in which the cuts were closer to the summit of the apex, so that the isolated pieces were larger, gave dorsiventral leaves instead of radials. But it should at least be considered whether the explanation of this difference is perhaps not that the larger isolated pieces included more apical tissue than the presumptive area of the leaf isolated, but that the smaller isolated pieces included less than that area, especially since, as pointed out, they appear to have been not quite correctly centred upon the angular position of I_1. For the farther the cut from the summit of the apex, the less will be the lateral extent of the piece isolated; and we have already pointed out[3] that in *Epilobium hirsutum* a lateral restriction of I_1 or of P_1 can make it develop into a radial leaf.

It is now becoming clear that isolated I_1 or I_2 presumptive areas develop very differently in different species of flowering plants. For in *Lupinus albus* we found that they developed only into dorsiventral leaves with leaflets[4]. Yet many of these leaves were very small, and most of them had no axillary bud (see, for example, ref. 4, Fig. 11). It is therefore probable that the isolated pieces from which they developed were smaller than the presumptive areas of the leaves isolated, and these pieces can scarcely have carried any surplus apical tissue.

In *Epilobium hirsutum* we find that isolated I_1 areas develop usually into radial leaves, though we have sometimes found dorsiventral leaves to develop from what were in effect isolated I_1 areas[5]. Potato shoots seem at present to be intermediate, since in them the I_1 areas which Dr. Sussex isolates develop into radial leaves, provided that the pieces isolated are not too large, while the I_1 and I_2 areas which we isolate develop into dorsiventral leaves, even when the pieces isolated are rather small.

We do not think that this discrepancy will be explained until both sets of results are illustrated with exact drawings, showing the positions of the cuts, and are also fully reported with details of the cultural conditions, the size of P_1 at the time of operation, and the variety of potato. Ours was King Edward. Nor do we think that the new experiments now reported by Dr. Sussex can profitably be discussed until they are similarly reported in detail. Only one point concerning them will be made here. The very large radial I_1's which he mentions were presumably large because their growth was freed from inhibition from the apex and from P_1 and P_2, which had all been removed, and not because they arose from specially large bases. So they do not really seem relevant.

We are continuing our experiments, and the situation seems complex. It may be necessary to onsider whether there is an apical influence orienting aves that would have been dorsiventral even withut it, as distinct from an apical induction of orsiventrality.

METAPHOSPHATE IN MYCOBACTERIAL METABOLISM

By FRANK WINDER and JOAN M. DENNENY
Laboratories of the Medical Research Council of Ireland, Dublin

DURING work on the effect on the metabolism of *Mycobacterium smegmatis* of some anti-tuberculosis compounds synthesized in these laboratories, attention became directed towards the phosphorus-containing constituents of this and other Mycobacteria.

In our experiments, quantities of *M. smegmatis* (of dry weight about 40 mgm.) were extracted with 10 ml. chilled acetone for several hours, twice with ice-cold 5 per cent trichloracetic acid for a total of 8 hr., twice with 5 ml. ethanol at 19° C., and refluxed with 5 ml. of 3 : 1 ethanol–ether. On extraction of the residues with 10 ml. trichloracetic acid at 90° C. for 15 min., most of the remaining phosphorus went into solution, leaving a residual amount assumed to be phospho-protein. The results of one such series of extractions are given in Table 1.

Table 1. PHOSPHATE CONTENT OF EXTRACTS OF *M. smegmatis*

Three-day old culture on Proskauer and Beck medium. 8·68 per cent nitrogen and 2·04 per cent phosphorus on dry weight basis

Method of extraction	Acetone	Cold trichlor-acetic acid	Ethanol, ethanol–ether	Hot trichlor-acetic acid	Residue
% of total phosphorus	0·6%	17·7%	3·9%	75 0% (nucleic acid phosphorus, 36 9%)	2·8%

Ultra-violet absorption studies on the hot trichloracetic acid extract showed that less than half the phosphorus in it was present as nucleic acid. The excess phosphorus could be extracted from the cells by milder agents than hot trichloracetic acid (see below), and studies were made on these extracts to determine the nature of this component. It could largely be precipitated by barium at pH 2·5, and was entirely hydrolysed to inorganic orthophosphate in 7 min. by N hydrochloric acid. This strongly suggested inorganic metaphosphate[1], which was confirmed by the fact that the extracts gave a metachromatic reaction with toluidine blue[1], and by paper chromatography[3]. The chromatographic results suggested that the inorganic metaphosphate originally had a high degree of polymerization. It is not known in what manner it is held in the cells; but from the difficulty experienced in extracting it separately from pentosenucleic acid it would appear that it is bound in a similar manner.

Three extraction methods were used in an attempt to extract the nucleic acids and the inorganic metaphosphate separately: (1) repeated extraction with trichloracetic acid at 19° C. for 12 or 24 hr. periods; (2) extraction with saturated urea at 37° C. for 24 hr.[3], followed by repeated extractions with 10 per cent sodium chloride at 19° C. for 12-hr. periods; (3) extraction for 12-hr. periods with $M/100$ bicarbonate buffer (pH 9) at 19° C. Each of these methods was, however, found to extract both pentosenucleic acid and inorganic metaphosphate, though at different rates. The first method was the most satisfactory, most of the pentosenucleic acid coming out in the first extract, while the inorganic metaphosphate was extracted much more slowly, and the deoxypentosenucleic acid was extracted only by hot trichloracetic acid. Table 2 illustrates this.

Table 2. EXTRACTION OF PENTOSENUCLEIC AND DEOXYPENTOSENUCLEIC ACIDS AND INORGANIC METAPHOSPHATE FROM *M. smegmatis* CELL RESIDUES (INITIALLY CONTAINING 3 00 mgm. NITROGEN) AFTER EXTRACTION WITH ACETONE, COLD TRICHLORACETIC ACID, ETHANOL AND ETHANOL–ETHER

Method of extraction	First extraction: trichlor-acetic acid at 19° C. for 24 hr.	Second extraction: trichlor-acetic acid at 19° C. for 24 hr.	Third extraction: trichlor-acetic acid at 19° C. for 24 hr.	Fourth extraction: trichlor-acetic acid at 90° C. for 15 min.
Metaphosphate phosphorus	92·1 μgm.	97 7 μgm.	66 1 μgm.	96 0 μgm.
Pentose-nucleic acid phosphorus	121·1 μgm.	49 8 μgm.	13 8 μgm.	None
Deoxypentose nucleic acid phosphorus	None	None	Trace	32 0 μgm.

Considerable amounts of pentose-containing substances (presumably polysaccharides[4]), and smaller amounts of substances estimating as deoxyribose by the Dische reaction, were present in the extracts, especially in the hot trichloracetic acid extract. Consequently, in differentiating pentosenucleic and deoxypentosenucleic acids, use had to be made of the difference in their absorption curves after heating in trichloracetic acid[5]. Afterwards, the use of the above trichloracetic acid extraction at 19° C. and then 90° C. provided a satisfactory method for the separation, and thus for the estimation, of the two nucleic acids in *M. smegmatis*. Since it was not practicable to separate either of the nucleic acids from inorganic metaphosphate, in studies with phosphorus-32 it was necessary to calculate their specific activities indirectly, having determined the content of deoxypentosenucleic acid (or pentosenucleic acid) and inorganic metaphosphate in an extract, and having determined the specific activity of the latter, isolated as the barium salt by precipitation at pH 2·5. The Schmidt–Thannhauser method did not give reliable results with this organism.

Similar results were obtained for the phosphorus components of *M. tuberculosis* RIRa (Table 3).

The presence of metaphosphate has been recorded in a number of lower organisms, for example, yeasts[6], corynebacteria[7,8], moulds[10] and algae[9], and its association with the metachromatic granules in these organisms has been pointed out. The subject has been reviewed recently[10]. After the work described in the present communication had been done, a paper by Ruska *et al.*[11] came to our attention in which the

Table 3. PHOSPHATE CONTENT OF FRACTIONS OF *M. tuberculosis* BIRa

14-day old culture on Lowenstein medium

Fraction	Soluble in cold trichlor-acetic acid	Lipide	Pentose nucleic acid	Deoxy-pentose nucleic acid	Inorganic meta-phosphate	'Phospho-protein'
% of total phos-phorus	27·0%	6·0%	29·8%	6·0%	27·0%	5·3%

presence of metaphosphate in *M. avium* was demonstrated, and its association with the polar granules in this organism shown.

The content of metaphosphate in *M. smegmatis* increases with the age of the culture, and the metachromatic granules correspondingly increase in frequency and size (Table 4). It has been found possible to cause the inorganic metaphosphate content to increase to a much higher level than was found normally. When lightly ground material from a 3- or 4-day old culture in Proskauer and Beck medium[12] was aerated at 37° C. in the same medium without the nitrogen source (asparagine), over a period of several hours only a very slight increase in the inorganic metaphosphate content of the cells occurred. If, however, 2·5 per cent tetrahydrofurfuryl alcohol was added, the inorganic metaphosphate per cell was doubled in 3 hr. and was increased threefold in 5 hr. The granules grew to an inordinate size. Studies using phosphorus-32 showed that increased formation of inorganic metaphosphate took place and consequently that the effect was not due to decreased utilization.

Table 4. VARIATION OF COMPOSITION OF *M. smegmatis* WITH AGE

Age of culture	2 days	3 days	4 days	6 days
mgm. nitrogen/ mgm. phosphorus	5·52	5·13	4·60	3·41

No other striking changes in cell composition or behaviour were observed. Respiration was scarcely affected by tetrahydrofurfuryl alcohol under these conditions, although in the absence of other substrates it caused an increased respiration-rate. Similar, but much smaller, effects on metaphosphate content have been obtained with both 2 per cent ethanol and 2 per cent tetrahydrofuran.

When the cells were aerated at 37° C. in the full Proskauer and Beck medium for five hours, the dry weight, total nitrogen, respiration, acid-soluble phosphorus, and pentosenucleic and deoxypentosenucleic acids increased, as expected. (The deoxypentosenucleic acid increased more slowly than the pentosenucleic acid at first—an increase in the latter was apparent after 1 hr., in the former only after 3 hr.; after five hours, the pentosenucleic acid had increased by a factor of 1·73, deoxypentosenucleic acid by a factor of 1·34; but by this time the rate of increase of the latter exceeded that of the former.) There was a slight falling off in the inorganic metaphosphate content which indicated a distinct drop in the amount per cell. The granules became smaller and partly hidden in a cytoplasm which now stained deeply with neutral red. When the experiment was carried out under the same conditions, but with the addition of 2·5 per cent tetrahydrofurfuryl alcohol, dry weight, nitrogen, respiration and pentosenucleic acid all increased at about the same rate as before, but acid-soluble phosphorus and deoxypentosenucleic acid increased more slowly. The inorganic metaphosphate showed a striking increase, almost as great as that in the absence of nitrogen. There was a corresponding increase in the size of the granules. Thus the novel situation was obtained in which actively growing cells, which normally allow their inorganic metaphosphate to drop, were instead increasing it far beyond the level normally attained in old cultures.

No stimulation of formation of inorganic metaphosphate in yeast was caused by tetrahydrofurfuryl alcohol.

The function of inorganic metaphosphate in the organisms in which it occurs is by no means clear. It is obviously a reservoir of phosphate, and has been shown to be partly used up during growth, and more completely in phosphate-starvation, and to be rapidly replaced when phosphate was provided[1,9]. The view was held[9,10] that the high inorganic metaphosphate content of 'resting' cells was due to the fact that it was not being used for synthetic purposes, as it was in growing cells. We have found this pattern to be followed up to a point in *M. smegmatis*, but the finding that in the presence of tetrahydrofurfuryl alcohol cell growth can occur without any substantial reduction in a very rapid rate of inorganic metaphosphate accumulation would seem to show that, in this organism at least, the pattern is more intricate than that suggested above. Our results suggest that inorganic metaphosphate is not rapidly used up by growing cells.

It seems open to doubt that inorganic metaphosphate exists only as a reservoir of phosphate, since it is unlikely that cells would keep a supply of phosphate sufficient to last for a couple of generations. It has been suggested[9] that, as a form of 'high-energy' phosphate[14], inorganic metaphosphate forms an energy reservoir. The energy stored in this form, however, would seem only to be equal to that liberated by cell respiration in about a minute. Attempts made in this laboratory to show that inorganic metaphosphate could provide energy for synthesis have not so far been successful.

Thus this work still leaves without a definite answer certain important questions. What is the main function of inorganic metaphosphate in mycobacterial and other cells? Is its high energy content of importance? In addition, new questions are raised. How does tetrahydrofurfuryl alcohol stimulate the formation of inorganic metaphosphate to such an astonishing extent, and interfere with the normal cycle of change of the metaphosphate content with the age of cultures?

Details of this work will be published elsewhere.

In conclusion, we wish to thank Dr. V. C. Barry for encouragement and for stimulating and critical discussion; Prof. E. J. Conway, of University College, Dublin, for providing facilities for work with radioactive phosphorus; and Arthur Guinness Son and Co., Ltd., for generously providing financial assistance.

Oxygen and Hæm in Invertebrates

THE quantity of hæmoglobin in solution in the blood of *Daphnia* is inversely proportional to the dissolved oxygen content of the water in which the animals live[1,2]. In the course of a few days *Daphnia* can change in tint from almost colourless to red, or the reverse, by the synthesis or breakdown of hæmoglobin. This occurs, too, in other branchiopod Crustacea (for example, Estheria, Apus, *Artemia*). Since a gain of blood-hæmoglobin with fall of external oxygen pressure is known also in man at high altitudes and fishes in poorly aerated water, one may ask if it occurs in all animals with hæmoglobin.

One of the most familiar invertebrate animals with abundant hæmoglobin in solution in the blood is the larva of the midge *Chironomus*. It lives in a mucous tube embedded in mud at the bottom of ponds. Keeping larvæ with well-aerated and poorly aerated water above the mud was found to have no influence on their hæmoglobin content. This may have been because the larvæ control the oxygen content of the water in their tubes; they draw in water by undulatory body movements, which are intermittent, the intervals becoming longer when the water is well aerated[3]. An attempt was therefore made to keep the larvæ without mud, but it failed because larvæ kept thus die in a few days. Young larvæ, however, freshly hatched from the egg, can live without mud. Fed on *Chlorella*, they grew and made mucous tubes, but frequently left them to swim in the water. These young larvæ formed more hæmoglobin in poorly than in well-aerated water. The partially and fully grown larvæ of another midge, *Anatopynia varia* (Fabr.), which make no tubes, also had more hæmoglobin in poorly aerated water.

The most familiar mollusc with hæmoglobin in solution in its blood is the ramshorn pond snail, *Planorbis corneus* (L.). Keeping adults for a month in water of high or low oxygen content had no effect on the redness of the blood; but newly hatched young reared in poorly aerated water became, in less than a month, redder than those grown in well-aerated water. It was not, however, found possible to influence the hæmoglobin content in the blood of annelid worms by changes in external oxygen concentration.

In the vertebrates hæmoglobin is found in muscle cells as well as in the blood. In invertebrates hæmoglobin occurs not only in blood and muscle, but also in nerve, fat and tracheal cells, cœlomic corpuscles, ova, parenchyma of rhabdocœles and bodies of Protozoa[4]. In mammals it is uncertain whether there is an increase in muscle hæmoglobin at high altitudes[5], but muscular exercise has this effect[6], owing perhaps to local oxygen deficiency. It was found that hæmoglobin increases and decreases in concentration in muscles and nerve ganglia of cladoceran and conchostran Crustacea just as it does in the blood, in response to paucity or sufficiency of oxygen in the environment. There was, however, no such effect of oxygen on the hæmoglobin content of pharyngeal muscles in the pond-snail *Physa*, or of the parenchyma in the rhabdocœle worm *Phænocora*.

Thus, among the invertebrates, in some but not all instances, hæmoglobin of blood or tissue cells fluctuates in quantity inversely as the oxygen pressure in the environment. Finally, cytochrome, detectable with the microspectroscope in muscles of *Daphnia* and Conchostraca, increases and decreases in concentration, like the hæmoglobins of blood, muscle and nerve, as the oxygen in the water decreases or increases. In mammals, too, an increase in the quantity of cytochrome in muscle occurs in response to a low atmospheric pressure[7]. It is curious, however, that the increase of cytochrome in mammals and Crustacea in response to diminished oxygen is the reverse of what occurs in baker's yeast, where the synthesis of cytochromes *a*, *b* and *c* is stimulated by air and inhibited by its absence[8,9].

A full account of this work will be published in the *Proceedings of the Royal Society*.

Passage of Glucose and Glycerol across the Red Cell Membrane

DURING recent years, increasing evidence has accumulated indicating that the passage of glucose across the human red cell membrane and of glycerol across the human and rabbit membranes is not a process of simple diffusion. The results of Wilbrandt and Rosenberg[1], Lefevre[2] and Widdas[3] show that the kinetics are not those of a simple diffusion process, and the effect of enzyme inhibitors indicates that at least specific adsorption sites are involved. The work of Lefevre[4] showed the inhibiting action of —SH agents; for example, *p*-chloromercuribenzoates, iodine and mercuric ions on glucose and glycerol transfer, the work of Jacobs and Corson[5] showed the inhibition of glycerol transfer by copper, and Wilbrandt[6] showed that glucose penetration is inhibited by lachrymators whereas glycerol remains unaffected. The passage of both glycerol and glucose is inhibited by phloridzin[4].

Though at first sight it would appear that the process is an active transfer involving an enzymic reaction providing energy other than thermal agitation, this is not necessarily so; and the process is perhaps better regarded as facilitated diffusion[7]. In this case the process differs from simple diffusion in being restricted by both structural and steric factors, and energy may be required for maintenance of structural units. It has been pointed out[7] that the distinction between active transport and facilitated diffusion may be one of degree only.

The present investigation was an attempt to study more closely the relationship between enzyme inhibition and the inhibition of facilitated diffusion by using irreversible inhibitors of the latter and showing strict parallelism to enzyme inhibition. The irreversible inhibitor chosen was 2–4 dinitrofluorobenzene. This substance was developed as a reagent for protein end-groups by Sanger[8] and also as a cytochemical agent by

Table 1

Inhibitor or added substance	Type of red cell	Effect on glucose		Effect on glycerol		Effect on sodium and potassium ions

	Rabbit			Nil	Nil	

Danielli[9]. It can react with —SH groups, $—NH_2$ groups and tyrosine. So as to make the information more specific, a second inhibitor was used—the diazonium hydroxide of *p*-nitraniline. This substance combines irreversibly with histidine, tyrosine and tryptophan, but not with —SH groups.

The effect of these two compounds and related substances on the entry and exit of glucose and glycerol into human and rabbit cells is summarized in Table 1.

The results are a strong indication that —SH groups are involved in the entry and exit of glucose but not in the passage of glycerol. It also appears as though tyrosine, tryptophan and histidine are not involved in either case.

In a consideration of the enzyme to which the dinitrofluorobenzene was attached, two possibilities were immediately suggested, namely, the esterases cholinesterase and phosphatase. The possible role of cholinesterase was considered because of the importance of this enzyme in the permeability of cells to sodium and potassium[10]. Preliminary investigations on the effect of the inhibitor eserine on the penetration of glucose and glycerol indicate, however, that cholinesterase is not involved in these cases. The second enzyme, phosphatase, has been thought to be of importance in glucose transfer in the red cell because of the inhibiting action of phloridzin and because of the similarity to glucose transfer in the kidney and intestine, where phosphatase is often considered to be the enzyme involved. The facilitated diffusion of glycerol is also inhibited by phloridzin, but as dinitrofluorobenzene inhibits the passage of glucose and not that of glycerol, different mechanisms for the two substances are probable. Thus, further work on the importance of phosphatase is indicated.

My thanks are due to Prof. J. F. Danielli for his suggestions, and to the Nuffield Foundation for a scholarship.

Independence of Delayed Fertilization and Spontaneous Triploidy in Mouse Embryos

IN the early mouse embryo, spontaneous[1] o experimentally induced[2] triploidy is thought to aris by fertilization of an unreduced diploid egg by haploid normal sperm. The possibility has not bee wholly excluded that the extra set of chromosome is derived instead from the male[3]—for example double fertilization or diploid sperm—or after delaye fertilization[4]. In the rat and rabbit, Austin an Braden[5] showed that experimentally delayed fertilization causes polyspermy; in the rat, chromosom counts at the first cleavage division showed that som dispermic eggs were triploid. It was suggested[6] tha some of the spontaneously triploid mouse embryo might have arisen in this way, and not by doublin of the maternal chromosomes.

To investigate this possibility in the mouse œstrus and timed ovulation were induced by th method of Runner and Gates[7]. Three- to four-wee old hybrid mice were brought into œstrus by tw intraperitoneal injections, the first a priming injectio of 2 I.U. of pregnant mare's serum, and then 36 hr later an ovulating dose of 2 I.U. of chorionic gonadotrophin (kindly supplied by Organon Laboratorie Ltd.). With the time of ovulating injection referre to as zero hour, egg recoveries from a large series o mice showed that ovulation was initiated and in al probability completed between 11 and 13 hr. Th injected females were then exposed to males eithe at 9–12 hr. (little or no imposed delay in fertilization) or at 17–22 hr. (delayed fertilization). Coitus wa scored by examination for vaginal plugs at 1- o 2-hr. intervals. Females without a vaginal plug a 23 hr. were left overnight with males (further dela in fertilization). In each daily series, some mice were subjected to delayed fertilization, some to undelayed, and a few were sacrificed at 11 and 12 hr. without mating, to detect any day-to-day variation in hormonal stimulation and time of ovulation. Eggs were recovered from all mated females at 3½ days fro the estimated ovulation time. Fertilized egg (morulæ and blastocysts) were analysed chromosomally as Feulgen squash preparations.

Absence of triploid embryos in mature females. Normal matings of sexually mature females of the same strains as used before indicated the level of spontaneous triploidy in uninjected mice. Of the 152 analysable embryos from 59 females, 148 were diploid and none triploid.

Immature females—ovulation time. Autopsies showed that ovulation had not begun by 10 hr. after the ovulating injection (16 mice), nor by 11 hr. (18 mice). Of thirty-eight mice autopsied at 12 hr., hirty-three (87 per cent) had ovulated. Of the mice utopsied after 13, 14 and 18 hr. (twenty mice per roup), all but one had ovulated. There was no ignificant difference in the mean numbers of ova per female between these last three groups, nor did hey differ significantly from the mean number of ggs, fertilized and unfertilized, recovered at 3½ days n the main experiment. The mean number of ova ecovered from ovulated mice at 12 hr. was one-half he number recovered at each later time. These esults indicate strongly that ovulation is initiated oon after 11 hr., reaches a half-way mark at 12 hr., nd is completed by 13 hr. from the time of the ovulatory injection. These limits are more narrowly defined, but within the same time-range as previously reported with different material and half our priming injection[8].

Immature females—incidence of triploid embryos after undelayed fertilization. Among the thirty-eight immature females placed with males at 9–12 hr. after ovulatory injection, nineteen exhibited vaginal plugs between 10–13 hr. (mean 11⅓ hr.). This group representing an 'immature control' series without imposition of delayed fertilization. Of the analysable embryos recovered at 3½ days, 127 were diploid; three (2·4 per cent) were triploid—two from a 10-hr. plug, one from an 11½-hr. plug. The high yield of eggs (mean, forty-three per female) is characteristic of superovulation in these immature hybrid mice. The relatively low number of analysable eggs is accounted for by those uncleaved, lost during preparation or not analysable.

Immature females—incidence of triploid embryos after delayed fertilization. Of the females exposed to males 17–22 hr. after ovulatory injection, seventeen showed vaginal plugs at 18–24 hr. (mean 19 hr. 20 min.). If 1½–3 hr. is allowed for sperm transport, sperm ripening, and time for penetration of the ovum, and with ovulation at 11–13 hr., these seventeen mice show a delayed fertilization of at least 5½ hr. and at most 16 hr. Of the analysable embryos, sixty-four were diploid and two (3 per cent) triploid, the percentage being higher than in immature controls, but not significantly so. Of females showing no vaginal plugs by 23 hr., six of those left overnight with males exhibited plugs the next morning. There can be little doubt that fertilization was substantially delayed in this group. An obvious retarded development and reduced fertilization-rate in eggs after late insemination gave internal evidence that fertilization had really been delayed. Yet of the twenty-three analysable embryos, twenty-two were diploid and none triploid, the incidence of triploidy being this time below that in immature controls, though not significantly so.

In summary (see Table 1), this experiment indicates, first, a slight non-significant incidence of triploidy in embryos from superovulated immature hybrid mice. Secondly, delayed fertilization by 5½ hr. or more has not resulted in an increased incidence of triploid embryos. Little or none of the spontaneous triploidy[1,2] reported among mouse embryos seems to be explained by Austin and Braden's suggestion of delayed fertilization. Either, contrary to their interesting findings in the rat and rabbit, delayed fertilization in the mouse does not lead to polyspermy; or polyspermic eggs which may have occurred did not become transformed into triploids; or triploids of such origin cannot be scored at 3½ days. Further, in experimentally induced triploidy in the mouse[3], delayed fertilization may be ruled out as a major intermediary between the stimulus imposed and the observation of triploids at 3½ days.

Table 1. MICE EXAMINED AND EGGS RECOVERED IN ADULT CONTROLS AND IN INJECTED IMMATURE FEMALES WITH OR WITHOUT DELAYED FERTILIZATION

	Adult ♀♀ controls	Immature ♀♀ with undelayed fertilization (mean 11⅓ hr. from ovulatory injection until plug seen)	Immature ♀♀ with delayed fertilization (mean 19⅓ hr. from ovulatory injection until plug seen)	Immature ♀♀ with extreme delay in fertilization (>20<37 hr. from ovulatory injection until plug seen)
Females used	59	19	17	6
Females with eggs	55	19	17	6
Females with analysable embryos	45	17	15	3
Females with triploid embryos	0	2	2	0
Egg classification				
Uncleaved, lost and not analysable	377	678	715	294
Diploid	148	127	64	22
Triploid	0	3	2	0
Others (tetraploid, aneuploid and chromosomal mosaics)	1+3?	1+2?	1+2?	1

A Possible Endocrine Mechanism controlling Locust Pigmentation

IT has been suggested that the changes in the coloration of locusts associated with swarming may be partly controlled by an endocrine mechanism[1], although until recently no experimental work has been available to support this view[2].

It is interesting to note, therefore, that injection of blood obtained from fourth-instar crowded (phase *gregaria*) hoppers of *Schistocerca gregaria* (Forsk.) into isolated-reared (phase *solitaria*) hoppers induces an increased black pattern and yellow or yellow-green background pigmentation in the next instar, that is, a change towards a *gregaria*-type coloration. When *solitaria* hoppers are injected as controls with an equal volume of insect Ringer or Tyrode's solution, or with blood from other *solitaria* hoppers, they retain the normal green background pigmentation with small amounts of brown or black melanin pattern.

The injection of *gregaria* blood into *gregaria* hoppers also produces no response.

It has been found that the degree of response to blood injections is dependent on the age of the insect; thus, maximum change in both pattern and background is obtained when mid-fourth-instar hoppers are injected. The compound (or compounds) involved in the change is not inhibited by acid or alkali and resists heat, though not prolonged boiling; its properties are therefore similar to those of other known insect hormones[3]. Ether-extraction of the *gregaria* blood suggests that the compound is ether-soluble, since this fraction was found to be as active in inducing changes in *solitaria* coloration as the non-treated blood, while the ether-insoluble fraction had little effect.

The present work, while tending to supply evidence of a blood-borne factor controlling phase pigmentation, does not preclude the possibility of genetical and environmental factors combining to determine the final type of the coloration, but tends to elucidate the physiological mechanism by which such factors are co-ordinated within the insect. The variation in the degree of colour change, according to the age of the hopper, emphasizes the importance of the relationship between hormone and tissue response in the system as a whole.

I wish to thank Prof. J. F. Danielli of King's College, London, and Drs. B. P. Uvarov and T. H. C. Taylor of the Anti-Locust Research Centre, for advice and criticism of this work, which is being done with a grant from that Centre.

Apparent Induced Enzyme Formation due to Co-enzyme Deficiency

Previous studies by Happold and Hoyle[1] and Dolby, Hall and Happold[2] made it appear certain that the enzyme tryptophanase was induced in cultures of *Escherichia coli* only in response to the presence of tryptophan in the medium in which the cell was grown. It was not developed in a complete amino-acid medium which also contained glucose but, as was shown by Evans, Handley and Happold[3], the tryptophan content of the medium remained unchanged, so that it was presumed that the fermentation of the carbohydrate gave conditions of culture comparable to the total absence of tryptophan in the medium. These studies were made either with enzyme preparations or with washed cells incubated with the substrate in the presence of toluene, which procedure reduced tryptophanase activity only slightly but did render the cells non-viable.

In recent experiments, in order to study different relationships, we have carried out a great number of experiments with washed cells which were still viable and which had been grown with forced aeration at 37° C. for 16 hr. on a basal medium of sodium succinate, 20 gm.; ammonium sulphate, 1 gm.; potassium sulphate, 1 gm.; sodium sulphate, 0·5 gm.; potassium dihydrogen phosphate, 9 gm. pe 975 ml. distilled water, to which after sterilizatio and adjustment to *p*H 7·0, 25 ml. of a sterile solutio of magnesium sulphate ($MgSO_4.7H_2O$) (10 per cen w/v) was added.

When grown on this medium, harvested and incubated with tryptophan, certain strains of *Escherichia coli*, particularly those recently isolated, showe a lag of 15–40 min. before indole production occurred whereas others showed an immediate but weak tryptophanase activity which remained for som considerable time. Neither type of cell suspensio produced a high tryptophanase activity within th space of two and sometimes three hours. The us of amino-acid media which were free from tryptopha also resulted either in cells which showed initial la or which possessed tryptophanase activity *ab initio* such cells, however, either developed or possesse greater enzyme activity than did those cells which ha been grown on the previously described basal medium

In the present communication, we record result of experiments performed two years ago relating t this problem of lag since we feel they throw light upon current studies in related fields. Tryptophanas is an enzyme dependent upon pyridoxal phosphate; any deficiency in the synthesis of pyridoxine derivative by the cells might produce a lag in indole formation. Similarly, a competitive utilization of pyridoxal phosphate by the amino-acid decarboxylases, which are so highly active in *Escherichia coli* grown in the amino-acid medium containing glucose, could also result in a lag in indole formation when such cells were incubated with tryptophan. We had previously tried the effect of adding pyridoxal phosphate to cells grown in the presence of glucose, with negative results, but unfortunately had not associated these experiments with our findings[2] that the glucose-induced lag was markedly reduced by reducing the concentration of sodium ions and increasing that of potassium ions in our system. The recent findings of Happold and Struyvenberg[4] that ammonium ions are better as activators of the tryptophanase system than potassium ions, and the latter than rubidium ions, changes the picture. Lichstein, Gunsalus and Umbreit[5] have shown that *S. faecalis* grown in media supplying DL-alanine instead of vitamin B_6 did not carry out transaminations; Gale[6] that such cells did not decarboxylate tyrosine unless pyridoxal or pyridoxal phosphate was added; Holden, Feirman and Snell[7] that cells grown in the presence of D-alanine contained not more than 5 per cent of the amount of vitamin B_6 present in organisms grown in the absence of D-alanine. Separate additions of L-alanine and DL-alanine to a concentration of 10^{-3} *M*, of DL-phenylalanine to 5 × 10^{-4} *M* and of tryptophan to 3 × 10^{-4} *M*, were made to the basal medium in order to test the effect of each of these additions in the induction of the tryptophanase system.

The cells from such cultures have been separated from the culture medium, washed in *M*/75 phosphate buffer *p*H 7·8 and resuspended in a further portion of the buffer solution. The cellular mass of the suspensions was standardized by determining the dry weight of 1-ml. samples of all suspensions tested; they varied from 2·5 to 6 mgm. per ml. In order to test their ability to produce indole from tryptophan (tryptophanase activity) a number of replicates were always prepared which contained 1 ml. of cell suspensions and 2 ml. *M*/75 phosphate buffer *p*H 7·8 (with or without 3 μgm. pyridoxal phosphate) and which were incubated at 37° C. for 10 min., after

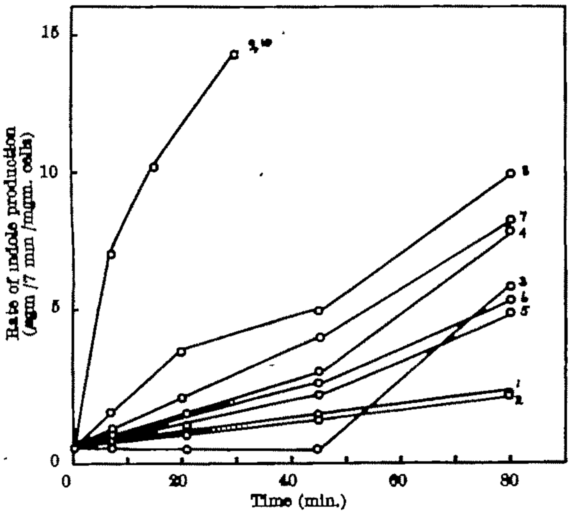

Fig. 1. Effect of the addition of certain amino-acids to a basal medium on the tryptophanase activity of cells of *E. coli* grown thereon.

Indole production per mgm. dry wt. of cells of *Escherichia coli*. 1, Cells from basal medium; 2, cells from basal medium + 3 μgm pyridoxal phosphate; 3, cells from basal medium + 10^{-3} *M* DL-alanine; 4, cells from basal medium + 10^{-3} *M* DL-alanine + 3 μgm. pyridoxal phosphate; 5, cells from basal medium + 10^{-3} *M* L-alanine; 6, cells from basal medium + 10^{-3} *M* L-alanine + 3 μgm. pyridoxal phosphate; 7, cells from basal medium + DL-phenylalanine; 8, cells from basal medium + DL-phenylalanine + 3 μgm. pyridoxal phosphate; 9, cells from basal medium + tryptophan; 10, cells from basal medium + tryptophan + 3 μgm. pyridoxal phosphate

which 2 μgm. l-tryptophan in 1 ml. buffer (also at 37° C.) was added. The indole produced was then measured at intervals from 7 min. to 180 min. after the onset of incubation. The results are presented in Fig. 1.

A Virus associated with Canine Encephalomyelitis

WE have recently isolated from the tissues of a dog dying of encephalomyelitis a transmissible agent which appears to differ in several significant respects from the known etiological agents of canine encephalitis.

The natural case was a four months old fox terrier which developed nervous symptoms and died one month after distemper prophylaxis by the virulent virus – hyperimmune serum technique. It was not examined clinically. Histopathological examination revealed an acute demyelinating encephalitis without evidence of formation of inclusion bodies.

The experimental disease is characterized clinically by a continuous high fever with the subsequent development of various symptoms referable to the central nervous system. Tremor, weakness, ataxia, disturbed reflexes and epileptiform seizures have been seen. The histopathological lesions are those of a demyelinating encephalomyelitis. In addition, in one case there was an interstitial pneumonia. In no case have inclusion bodies been found in the brain or elsewhere. The sera of experimentally infected puppies (including one which survived forty-nine days *post inoculationem*) have shown no development of complement-fixing antibodies when tested against canine distemper virus and contagious canine hepatitis virus.

The experimental disease has been set up by the inoculation of tissue suspensions treated with 500 units of penicillin and 100 micrograms of streptomycin per ml. administered in intrathecal and intraperitoneal routes. In no case has any evidence of cultivable bacteria been found. Attempts are being made to cultivate the agent in the chick embryo; the results to date are equivocal.

The findings reported herein are of interest as they tend to incriminate a virus or virus-like agent distinct from those known to be capable of causing canine encephalitis. Much work will be required before such a hypothesis can be adequately supported; meanwhile, it is believed that the subject of the etiology of canine encephalitis is of sufficient general interest to warrant publication of these preliminary observations.

Preservation of Bacteria

BACTERIA may be preserved by drying suspensions either from the frozen or from the liquid state. Of these two methods, the former, particularly in the form of centrifugal freeze drying[1], has been widely used because of its efficiency and convenience.

A method which differs from previous ones and which appears to be worth serious investigation is at present being studied. In outline, it consists of dehydrating the viscous product which results when a small volume of bacterial suspension is incorporated in a mass of previously freeze-dried material.

The results shown in the table were derived from some early experiments with this method.

Organism	Survival (per cent)			
	1	2	4	8 months
Sh. flexneri	93	100	83	82
Salm. stanley	91	82	85	70
Salm. typh.	87	87	91	80
Str. viridans	80	80	69	63

Glass ampoules of 8 ml. capacity were found to be convenient for quantitative studies. A mixture of 6 per cent peptone (Evans) and 1 per cent soluble starch (B.D.H., 'Analar') was sterilized by autoclaving and dispensed into the ampoules in 1·5 ml. quantities. After freezing the mixture at – 20° C. for at least 5 hr., it was dried *in vacuo* for c. 18 hr., the water vapour being condensed on a refrigerated coil at – 40° C. The solids were left in the form of compact cylindrical plugs c. 13 mm. in diameter and c. 10 mm. in depth. The ampoules were stored in air-tight jars.

The manifold on which the inoculated ampoules were dried was a simple brass model with side-arms of rubber tubing which could be opened or closed with steel spring clips. Before the ampoules were inoculated, the manifold with the arms closed was connected to a 'Speedivac' pump with a phosphorus pentoxide trap. By means of a small leak in the manifold, the pressure was adjusted to c. 10 mm. mercury.

The suspensions used for the inoculation of the plugs were prepared by diluting nutrient broth cultures of the organisms 1 : 250 with 5 per cent glucose. Cultures at or near the end of the logarithmic phase were used. By means of a capillary pipette tipped with paraffin wax to which a syringe was attached, a single drop (c. 0·02 ml.) of the suspension was discharged on to the surface of each plug. As soon as each ampoule had been inoculated it was connected to a manifold arm which was then opened. Usually, 12–18 ampoules were inoculated at a time. Approximately 5 min. after the last ampoule had been connected, the leak was closed and high vacuum (c. 0·01 mm.) was established. The ampoules were taken off one at a time, constricted, replaced on the manifold and finally sealed off *in vacuo* after 1 hr. The ampoules were stored at room temperature in the dark.

The immediate effect of the inoculation of the freeze-dried plug is a localized viscous solution of the solids. Wetting of the entire plug is prevented by subsequent rapid removal of water by the pump. The exposure of the plugs to the higher pressure (10 mm.) induces a mild foam which may rise 1–2 mm. above the surfaces of the plugs; at the lower pressure (0·01 mm.) dehydration of this viscous foam proceeds very rapidly.

Some preliminary experiments have shown that the method may be simplified where percentage estimates of survival are not required. Smaller plugs (0·25 ml.) in tubes of ¼ in. diameter have been 'stab' inoculated by means of a straight wire charged with bacterial suspension. With such modifications no visible foaming of the peptone has occurred under reduced pressure, and drying *in vacuo* has been achieved by exposure of the plugs to high vacuum as soon as they have been inoculated.

At present a number of factors are being investigated in relation to the method. Meanwhile, it is of interest that the survival-levels shown in these early experiments compare favourably with those obtained by previous drying methods.

I am indebted to the Medical Research Council for a personal research grant.

Egg-laying in Ctenophora

WHILE occupied with field-work on Siphonophora, I placed six small *Pleurobrachia* sp. measuring about 2·5 mm. in length in a watch-glass at 1100 hr. on April 29. An hour later I noticed that eggs were being extruded through the ectoderm over the gastrovascular canals. Since the fertilization membrane was present as the eggs were being extruded, it would appear that fertilization took place inside the meridional canals. By 1430 hr. the first and second cleavages of the majority of the eggs were taking place as in *Beroe*. By 1830 hr. the numerous micromeres were covering the macromeres by epiboly and many of the larvæ had reached the stage of gastrulation. Within twenty-four hours of extrusion the larval ctene-plates could be seen beating within the egg envelope. The same phenomenon was witnessed with another batch of *Pleurobrachia* on May 7, when less than half the eggs segmented.

A recent text-book states that ripe sex cells in Ctenophora are discharged through the mouth except in *Coeloplana* and *Ctenoplana*, in which the testes open on the aboral surface by ducts.

I am informed by Miss M. A. Harvey, who confirmed my observations of April 29, that she has observed eggs being extruded through the ectoderm in a similar way in *Beroe ovata* and *Lampea pancerina*; but in the former, development of the eggs did not take place, while the eggs of the latter were not kept.

Permeability to Water of the Lamprey Integument

THE relationship between the anadromous lamprey, *L. fluviatilis*, and the purely fresh-water form, *L. planeri*, has been the subject of much discussion, and doubt has sometimes been expressed as to whether they should be regarded as distinct species. As Weissenberg[1] showed, although there are profound differences in the biology of the two forms, there are no important morphological criteria (other than size) by which they may be differentiated. It is therefore of especial interest to find that significant physiological differences exist between these species in regard to the permeability to water of the integument.

The rate of osmotic uptake in fresh water has been determined by weighing at intervals animals in which the urino-genital papilla has been ligated. In the sexually mature animal, the possibility of water absorption in the gut can be excluded, since the fore-gut is no longer patent. Expressed as percentage increases of weight, the mean rate for *fluviatilis* was found to be 1·1 per cent per hr. in tap water at 13·5° C., compared with 5·1 per cent per hr. for *planeri* in tap water at 12° C. As measured by the thermoelectric method, the osmolar concentration of the blood of *fluviatilis* at the time of the experiments varied from 135 to 150 m*M* with a mean value for six animals of 143 m*M*; the corresponding mean value for a large number of determinations on *planeri* was 110 m*M*. The osmotic gradient in tap water is therefore rather greater for *fluviatilis*, and hence the difference in permeability between the two forms would appear to be even greater than is indicated by the rates of uptake of water.

The rate of flow of urine implied in these figures is, for *planeri* at least, far in excess of that recorded for any other aquatic vertebrate in fresh water, and even the reduced rate in *fluviatilis* is about twice that of the eel[2], the skin of which bears a resemblance to that of the lamprey.

These results are in general agreement with those obtained for the rate of loss by osmosis in hypertonic solutions. In Fig. 1, the mean percentage hourly

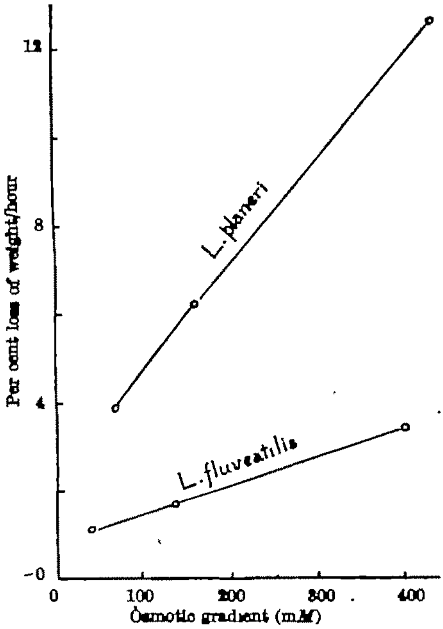

Fig. 1. Osmotic loss of water in sea water and sea water dilutions

losses of weight have been plotted against the approximate osmotic gradients in the various concentrations of sea water used. Interpolating from these curves, the osmotic losses for concentration gradients similar to those experienced in tap water (but in the reverse direction) are for *planeri* 4·6 per cent/hr. and for *fluveatilis* 1·7 per cent/hr.

Such differences between the two species are sufficient in themselves to explain the much greater tolerance shown by *fluveatilis* to direct transfer from fresh water to sea water. Whereas *planeri* survives only for a few hours in sea water diluted with two volumes of tap water and succumbs in an hour or so in pure sea water, *fluveatilis* will often survive indefinitely in equal parts of tap water and sea water and may live for several hours in pure sea water. But, although the lower water permeability of *fluveatilis* offers some immediate relief from the difficulties encountered in moving from fresh to salt water, it may well be that this characteristic would be of greater significance for an animal returning to fresh water from the sea. It seems reasonable to suppose that for *planeri* in fresh water the kidney is working close to the upper limits of its capacity, and that substantial increases in the concentration gradient could not be tolerated. It is perhaps for this reason that ammocoetes and adults in which the internal concentration has been raised by a period in hypertonic saline solutions sometimes die when returned to tap water. There are reasons for believing that the osmolar concentration of the blood of *fluveatilis* when it first leaves the sea on its spawning migration would be considerably higher than in the animals employed in these experiments, and a lower level of permeability to water may therefore be essential to their survival during this phase of the life-history.

The Wet-film Indian Ink Method for examining Micro-organisms

RECENT experience with the wet-film indian ink method, used by Duguid[1] for demonstrating bacterial capsules and slime, suggests that it can be used for examining the structure of a wide range of living micro-organisms. To be effective for this purpose, an ink should have very small, uniformly sized particles, should spread evenly and should not coagulate too readily. These requirements are met by 'Pelican' black drawing ink, though it does coagulate to some extent in acidic suspensions. Several other inks proved unsatisfactory, chiefly because of larger and more variable particle-size.

With small unicellular organisms it is generally best to mount in undiluted ink. A drop (about 0·01 ml.) is placed on a clean slide, and the organism, preferably from a young growth on a solid medium, is gently mixed into it with a loop. Where it proves difficult for any reason to obtain a satisfactory density or distribution of organisms, a suspension may be prepared in a small loopful of water prior to mixing with the ink. A No. 1 coverslip is placed on the suspension which is then further spread out by pressing slide and coverslip firmly between blotting paper. The optimum thickness of film varies with the size of organism and may be determined by trial; in general, portions of film medium to dark brown in colour are satisfactory for examination with 1/12 oil-immersion objectives.

Such preparations may be used for demonstrating not only bacterial capsules, as Duguid showed, but also bacterial spores. Stages in spore formation may be seen, for example, with *Bacillus megatherium* grown on potato agar at 27° C. for 18–24 hr. With this species it is possible to see other details of internal cell structure. The structure of yeast cells can be seen by mounting in indian ink, and rewarding preparations can be made of a species such as *Schizosaccharomyces octosporus*, grown on malt agar at 25° C. for seven days, to demonstrate stages of ascospore formation. One important advantage of this wet-film method is that artefacts are largely avoided; further, there is little evidence that the ink is toxic to organisms, since in dilute suspensions motile bacteria remain active for some time.

Preparations provide good subjects for photography: motion of cells induced by intense Brownian movement of the ink particles, which might interfere, can be limited by adjusting the thickness of the film so that cells are just held between slide and coverslip. Mounts can often be preserved for 24 hr. or more in a moist chamber at 5° C.

With fungi, it is usually desirable first to obtain mycelial growth over a glass coverslip or square of 'Cellophane' lying on an agar medium. Mycelium is best mounted in ink diluted 1 : 5 to 1 : 10 with water, one convenient method being to make an ordinary water mount and then to introduce a loopful of ink which can be dispersed with a minimum of disturbance to the material. Coverslips with mycelial growth may be mounted directly, only slight pressure being applied to slide and coverslip to spread the diluted ink suspension. Mycelial growth on 'Cellophane' can sometimes be transferred directly to a slide (by placing it face downwards, pressing gently, and then stripping the 'Cellophane' off); but where this is not possible, a small piece of 'Cellophane' is cut from the square and placed face upwards on the slide. In either instance the mount is made with diluted ink. By this means preparations can be made of a variety of fungal material, including that obtained directly from infected plants, results being particularly valuable when such material is delicate and subject to distortion by fixing, as, for example, with asci of *Eremascus*.

The Cuticle of Nematode Larvæ

The infective larval stage of many nematode parasites is ensheathed in the uncast cuticle of the second stage. The sheath is regarded as having some protective function in a larval stage which is more resistant to environmental fluctuations than the earlier stages. A method has been devised for separating the sheaths from larvæ, and it has been found that their protein complement is water-soluble. In this communication, the amino-acid composition of these proteins is discussed.

Mixtures of third-stage larvæ of *Oesophagostomum*, *Ostertagia*, *Chabertia*, *Haemonchus* and *Trichostrongylus* from sheep were examined. Pure samples of *Haemonchus contortus* larvæ were also used.

Exsheathment was obtained *in vitro* using solutions of sodium hypochlorite, as described by Lapage[1]. As soon as exsheathment occurred the larvæ were centrifuged, the supernatant removed and the cuticles separated from the active larvæ by differential centrifugation in saturated sodium chloride. The cuticles were then washed five or six times in distilled water and placed in sealed tubes at 105° C. for 12 hr. This caused the solution of the cuticles in distilled water, leaving a slight residue which microscopically was seen to be plant debris and which gave a negligible ninhydrin reaction after acid hydrolysis.

The cuticles in solution were hydrolysed in sealed tubes at 105° C. in 6*N* hydrochloric acid for 24 hr. The hydrolysate was examined by two-dimensional paper chromatography using 80 per cent ethanol and water-saturated phenol as solvents.

By comparison with a prepared map of known amino-acids, the presence of nine amino-acids was demonstrated in the hydrolysates of both mixed collections and pure samples of *Haemonchus contortus*. These amino-acids in approximate order of the amounts present were proline, hydroxyproline, aspartic acid, cysteic acid, glutamic acid, alanine, leucine, glycine and valine. This order was obtained on considering the size of the spot and the sensitivity of the different amino-acids to ninhydrin as estimated by Dent[2]. The first four were recognized by their position, colour and conformation. The presence of leucine and valine was verified using a marker procedure. Proline was detected by its colour in ninhydrin and isatin; hydroxyproline by its similar colour in ninhydrin and isatin and its specific red colour on the application of Ehrlich's reagent after isatin. Glycine was recognized by its colour, and though its position on the map could have been shared with arginine and serine, these two amino-acids were proved to be absent by other tests. Tests for cystine and tyrosine also gave negative results.

The presence and composition of water-soluble exoskeletal protein in the Invertebrata has been firmly established in the Insecta by several workers, most recently by Hackman[3]. The presence of somewhat similar water-soluble protein in the nematoda has also been demonstrated in the cuticle of *Ascaris* by Chitwood[4] and the amino-acid composition of an 'albumen' in the outer layer of fertilized *Ascaris* eggs has been demonstrated by Kreuzer[5]. It seems probable that water-soluble exoskeletal proteins may occur over a wide range of the invertebrate animals.

I am indebted to the Science and Industry Endowment Fund of the Commonwealth Scientific and Industrial Research Organization for a personal grant. Assistance provided by the Agricultural Research Council is also acknowledged.

Newly Fallen Snow and Air Temperature

The physical features of a layer of fallen snow at a given time are chiefly dependent on (1) meteorological conditions while the snow is falling, and (2) meteorological factors which occur later causing metamorphosis of the snow.

Some observations I have made in the Italian Western Alps have shown that the apparent density of newly fallen snow is variable and depends on air temperature during the fall. On account of the lack of systematic high-altitude observations in Italy showing low negative temperatures (centigrade), I have worked on the accurate data gathered at the Weissfluhjoch (2,540–2,660 m.), near Davos (Switzerland), already published[1]. Excluding the cases of new snow less than 10 cm. deep and snowfalls occurring with strong wind (causing *Schneetreiben*), as well as those with air temperature reaching or near 0° C., it was found that the apparent density of the newly fallen snow depends upon the mean air temperature during the fall (see Fig. 1). The mean values of the air temperature are somewhat approximate, as deduced from the maximum and minimum temperatures, as well as from observations at 7 hr. 30 min., 13 hr. 30 min. and 21 hr. 30 min., during the time of snowfall; however, they are referred to the

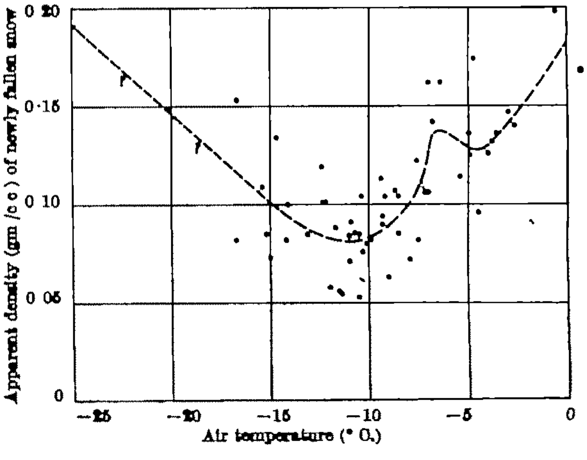

Fig. 1

separate values of the apparent density, because this was obtained from the top of the new snow and from the corresponding water content, both observed only at 7 hr. 30 min.

Although the cases considered are only 53 (+ 2 near 0° C.), Fig. 1 indicates that at Weissfluhjoch the maximum frequency of snowfall occurs with air temperature near − 11° C. For air temperatures less than − 17° C. snowfall seems very rare, and only one case was recorded with a temperature at nearly − 25° C. (on March 4, 1949).

As regards the apparent density of the newly fallen snow, Fig. 1 indicates that it reaches a minimum value near − 11° C. However, the behaviour between − 5° and − 7° C., where the scattering is great, is uncertain; but the extrapolated curve appears the most probable. It is to be noted that near − 4° C. the points reveal a minimal dispersion.

The results obtained are believed not to be restricted to the Weissfluhjoch, where the position of the observatory nearly at the top of the mountain assures that there is little difference from the free atmosphere at the same height during snowfall. Indeed, from laboratory investigations, W. Rau and other authors[2] demonstrated that the greatest frequency in the spectrum of the ice-forming-nuclei occurs between − 10° and − 12° C., while a secondary maximum lies near − 4° C. As the ice nucleation in the atmosphere is the same as in the laboratory[3], it is obvious that the greatest frequency of snow should occur near − 11° C. when the appropriate meteorological condition for precipitation exists in the atmosphere. (*Note added in proof*. Using the meteorological observations made in different observatories at the top of high mountains (cf. Bossolasco, *Geofisica pura e appl.*; in the press) the above results have been proved to be general.)

With reference to the corresponding minimum apparent density of the newly fallen snow, E. Wall and U. Nakaya have already pointed out that the form of ice-crystals also changes with temperature. Near − 11° C. the stellar form prevails, and this explains the minimum density of the snow at this air temperature.

Solar Tides in the Lower Stratosphere

WHILE methods of representing the 100-mb. wind field were under investigation, diurnal and semi-diurnal variations were detected in winds observed at the 100-mb. level from British upper air stations. These periodic variations of wind appear to be associated with the atmospheric solar tides. 100-mb. wind observations are particularly suitable for study in connexion with tidal oscillations, since, at least between latitudes 30° N. and 60° N., the synoptic variations of wind are considerably smaller at that level than in the upper troposphere. The lower stratosphere is also free from the smaller-scale effects which may mask tidal wind variations occurring in the lower troposphere.

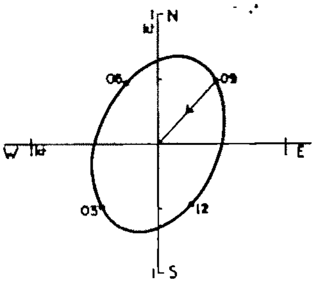

Fig. 1. Vector diagram giving the wind velocity due to the semi-diurnal oscillation. The wind velocity at any time is defined by the line joining the appropriate point on the ellipse to the origin

The deviations of the annual mean south and west 100-mb. wind components at 0300 G.M.T., 0900 G.M.T., 1500 G.M.T. and 2100 G.M.T. from the respective overall annual mean wind components were computed from two years wind observations made using *G.L.*III radar equipment. Similar deviations for 0600 G.M.T., 1200 G.M.T., 1800 G.M.T. and 2400 G.M.T. were obtained from unpublished 150-mb. observations supplied to me by H. W. L. Absalom. The latter refer to four years of wind observations made, for the most part, by radio direction-finding techniques. Harmonic analysis yielded the following expressions for the annual mean oscillation of each component:

$$100\,S = -54\cos(\theta + 32°\,14') + 67\cos(2\theta + 44°\,24');$$
$$100\,W = 51\cos(\theta + 84°\,24') + 51\cos(2\theta - 29°\,3');$$

where S and W are the south-wind and west-wind components in knots and θ ranges from 0 to 360° as time varies through 24 hr. from 0300 G.M.T. The third and fourth harmonics were not statistically significant.

The semi-diurnal oscillation is illustrated by Fig. 1, which is a vector diagram giving, for any time, the wind velocity due to the oscillation. The stratospheric oscillation is approximately in phase with the surface wind oscillation derived theoretically by Bartels[1] from Simpson's expression[2] for the semi-diurnal variation of surface pressure. Such a relationship is to be expected from tidal theory[3]. The amplitudes of the lower stratospheric wind component oscillations, 0·67 knot and 0·51 knot for the south- and west-wind components respectively, are of comparable magnitude to the amplitude of Bartels's derived surface-wind component oscillations in latitude 55° N., namely, 0·87 knot for the south component and 0·85 knot for the west component.

The diurnal oscillation is given by Fig. 2. The amplitudes of the diurnal and semi-diurnal oscillations are similar in the lower stratosphere. Fig. 3 gives the resultant wind velocity due to the combined diurnal and semi-diurnal oscillations.

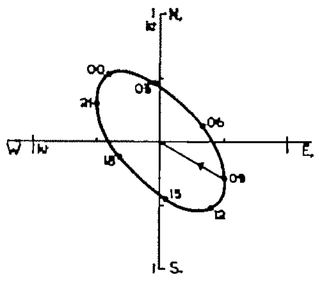

Fig. 2. Vector diagram giving the wind velocity due to the diurnal oscillation. The wind velocity at any time is defined by the line joining the appropriate point on the ellipse to the origin

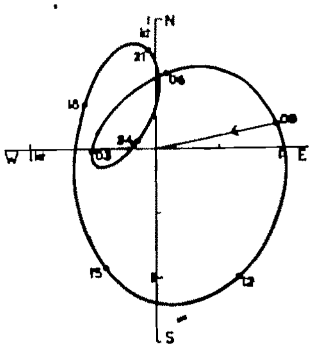

Fig. 3. Vector diagram giving the resultant wind velocity due to the combined diurnal and semi-diurnal oscillations. The wind velocity at any time is defined by the line joining the appropriate point on the curve to the origin

Electron Irradiation of Polythene

CONSIDERABLE attention has recently been given to the effects of high-energy radiation on polymeric substances[1]. The effects would appear to be of the same fundamental character whether X-rays, electron bombardment, or the mixed radiations of the atomic pile are used; it is reported that in the absence of oxygen the dominant reactions are either cross-linking or chain-scission, and polymers have been classified according to their behaviour in these respects when irradiated. Some of the most interesting effects have been observed in polythene, where cross-linking causes major changes in physical and mechanical properties, particularly at temperatures above the crystalline melting point.

Experimental work to date has of necessity been performed with whatever source of radiation was available, and this has sometimes imposed severe restrictions on the scope of the investigations. When X-rays are used little energy dissipation occurs in the material and very long exposures are required, while use of the atomic pile imposes a fixed and high ambient temperature, exposures are still long, and often specimens can only be withdrawn when the pile is opened for other purposes. Bombardment of a specimen directly by means of an electron beam, on the other hand, gives good energy dissipation and experimental conditions may easily be controlled. It is required, however, that both the electron energy and the current density should be high, so that thick specimens can be treated with short exposure times. The development of the travelling-wave linear accelerator has provided an equipment which fulfils these requirements. Machines of this type operating at 8 MeV.[2] and at 4 MeV.[3] are being used as X-ray generators for clinical purposes, and one of the latter units has been adapted for the electron irradiation of specimens by extracting the electron beam through a thin copper window.

At the nominal maximum rating of the machine, 500 W., a mean current of 125 μamp. is obtainable, and for experimental purposes the window scatters the beam so as to give almost uniform coverage over an area 20 cm. in diameter at a distance of 70 cm. from the window. Further, it is found that the effect of irradiation throughout the specimen may be fairly uniform, varying only by about ± 10 per cent over a substantial part of the electron range (about 2 cm. in polythene for 4-MeV. electrons).

A detailed investigation of the behaviour of polythene when bombarded by 4-MeV. electrons is now in progress, and some of the preliminary results are indicated below.

It is well known that a sufficient degree, α, of random cross-linking produces from an initially soluble polymer a gel fraction the magnitude of which, x, is determined by the original molecular weight distribution, $W(m)$. For polymers cross-linked by radiation, the relationship between these three parameters is often complicated by chain-scission. If, as is probable, this is a random process occurring to an extent proportionate to α, then x has been shown to approach a limiting value, x_L; this limiting value is determined by the ratio, β, of main chain-scissions to atoms cross-linked[4]. In practice, however, x_L can only be measured at reasonable degrees of cross-linking on the often uncertain assumption that the initial polymer contains little low-molecular weight material.

The development of a soluble fraction can, on the other hand, be clearly observed when the extracted gel fraction of a lightly cross-linked polythene is further irradiated (see Fig. 1).

This experiment gives a positive demonstration of the occurrence of chain-scission; and the results suggest that the limiting soluble fraction lies between 2·4 and 2·8 per cent. This value is appreciably less than that previously suggested for polythene irradiated in an atomic pile on the basis of an assumed simple exponential distribution of molecular weights[5]. Corresponding to the range of values observed for the limiting soluble fraction, the value of β lies between

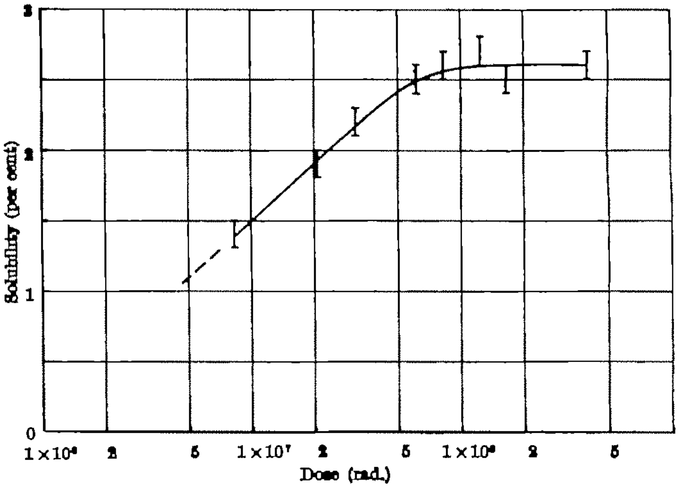

Fig. 1. Soluble material formed by the irradiation of a polythene gel fraction
Note. Soluble fraction of original gel is 0·4 per cent; dose is expressed in rads. (see *Nucleonics*, 12, No. 1, 11). 1 rad. = 100 ergs./gm.

0·18 and 0·20. With this knowledge, it is possible to estimate with reasonable accuracy the gel fractions which would be obtained if no chain-scission occurred. One of us (A. C. B.) has applied this information to the calculation of the original molecular-weight distribution-functions of a series of polythenes, with the necessary exception of the low-molecular weight tails. The results obtained suggest that polythenes have wide molecular-weight distributions, such as have been indicated by a comparison of number-average molecular weights with weight-average molecular weights determined by light scattering[6]. This work will be reported more fully elsewhere.

Surface Films of Poly-di-methyl Siloxanes on Organic Liquid Substrates

IN contrast with organic compounds, there is evidence that small quantities of silicones are capable of exerting marked surface activity when incorporated in organic liquids. Often this activity is manifest even when the silicone is immiscible with the organic liquid. Such effects could imply that the activity arises, not through adsorption at the air/solution interface, but rather through the existence of insoluble films analogous to those established for aqueous substrates.

This communication records some preliminary evidence for the existence of such films of a poly-di-methyl siloxane of viscosity 20 centistokes. This material of average molecular weight about 2,000, corresponding to a chain of twenty-five di-methyl-siloxane units, was applied as a solution in ether, in small quantities, to the surface of a number of liquid substrates, and the surface tension lowering was determined by the Wilhelmy method, the force being measured by means of a torsion wire and a suitable optical system.

Initially, a large lowering of tension resulted after addition of the silicone to the surface, which decreases usually in about ten minutes to a steady value; in isolated cases this value remained steady within 0·25 dyne overnight. As a proof of the existence of these films the surface pressure could be raised or lowered by varying the area of the film with a specially constructed barrier consisting of a strip of brass thick enough to extend below and above the interface by a few millimetres and sealed to the brass sides of a rectangular trough by mercury–brass amalgam. Changes in area resulted in hysteresis in the pressure such that, for example, compression gave immediately a high pressure which decayed to a lower value, while on returning to the original compression the final pressure was lower by less than 1 dyne from that at the beginning of the cycle. Variation in compression of the film-free side of the barrier gave no evidence of changes in pressure. In spite of this barrier method, and because of the ever-present danger of leakage across the mercury barrier, most of the measurements were made on a constant area by varying the amount of silicone added.

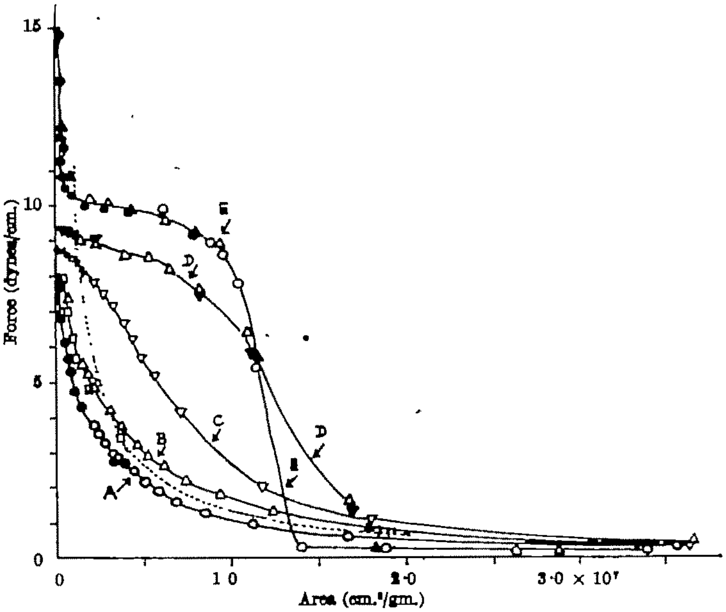

Fig. 1. Force–area curves for poly-di-methyl siloxane (*D.C.*200) at the interface of air and various substrates: (*A*) oleic acid; (*B*) olive oil; (*C*) tri-acetin; (*D*) ethylene glycol; (*E*) distilled water. The dotted curve is calculated for a gaseous film of molecular weight 2,000

Fig. 1 shows some typical force-area diagrams for a number of substrates. It is clear that the substrate has a marked influence in varying the compressional behaviour of the film, varying from that suggestive of a gaseous state to that suggesting phase transitions. Examination of the films by dark-field illumination at the highest compressions and even with a spread drop of the undiluted siloxane failed to reveal any so-called 'point structure' or patches[1] of unspread material.

Some observations were also made on the spreading of drops of the undiluted siloxane. On all the substrates examined, the drop lost its identity immediately and the spreading film at intermediate thicknesses gave readily observable interference fringes of remarkable regularity, which finally disappeared with continued spreading. Lycopodium powder was found to be the most generally useful means of detecting the presence and location of films, and was used for measuring the rate of advance of a spreading film. The substrate was contained at a depth of about 0·5 cm. in a rectangular trough of length 95 cm.

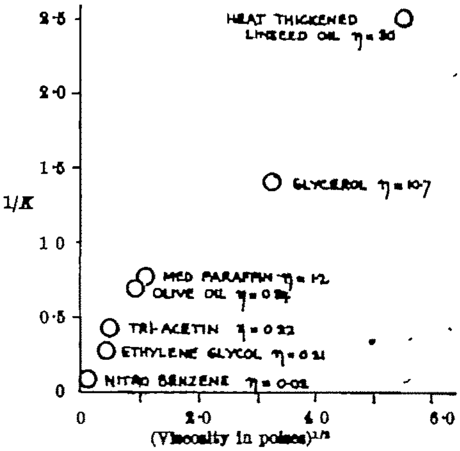

Fig. 2. Relationship between spreading-rate constant and viscosity of substrate

and width 2 cm. A drop of siloxane was placed on the surface at one end and the distance spread at different times indicated by movement of a small quantity of lycopodium powder gently blown on to the surface. It was found that for all the liquids examined the distance l travelled in a time t was accurately represented (for distances of at least 50 cm.) by $l = kt^{1/2}$, and of particular interest is the dependence of the rate constant k on the viscosity of the substrate.

General considerations suggest that k might be expected to show an inverse dependence on the square root of the viscosity of the substrate; that this is approximately so is demonstrated in Fig. 2. This relationship is remarkable when one considers the variation in chemical nature of the substrates and that their viscosities vary by some 1,500-fold.

The bearing of these results on the mechanism of spreading will be elaborated in a fuller publication of this work.

I wish to acknowledge some preliminary measurements made by Mr. J. Beasley, and also the assistance of Mr. R. Golledge in some of the spreading measurements. This communication is published by permission of the Director and Council of the Printing, Packaging and Allied Trades Research Association.

Angle of Contact of Mercury against a Moving Tungsten Wire

DURING preparations for the measurement of the density of mercury by weighing in it a cube of tungsten carbide of known volume, it was necessary to measure the surface tension force exerted by the mercury on the 0·002-in. diameter tungsten wire used to suspend the cube. The method developed for measuring the angle of contact and the behaviour of the angle of contact against an oscillating wire may be of more general interest.

The mercury surface around the point of entry of the wire was photographed through an optical system such that no light entered the camera from those points of the surface at which θ, the angle of inclination of the surface to the horizontal, exceeded a value ψ governed by the geometry of the optical system.

At a distance x from the axis of the wire,

$$\sin \theta = \sin \theta_0 \,.\, K_1 (bx)/K_1 (ba),$$

to a very good approximation. θ_0 is $(\alpha - \pi/2)$, where α is the angle of contact at the wire; $b = (g\rho/\gamma)^{1/2}$ where ρ is the density and γ the surface tension of mercury; and $K_1(bx)$ is the modified Bessel function of order unity. When $\theta = \psi$, x is the radius of the unilluminated part of the image of the mercury surface. Hence, from x measured on the photograph, θ_0 can be deduced. This method of finding θ_0 should be applicable to other liquids and other forms of boundary (although the equation to the surface would then be different). The method should be especially useful when the surface is inaccessible.

The balance from which the tungsten carbide cube was suspended was set oscillating (the period being about 32 sec.) and photographs were taken at intervals of 2 sec. The variation of angle of contact, shown in Fig. 1, was periodic but not sinusoidal. The form of the curve appears to indicate that there is a non-linear frictional contact force. A frictional contact force has been postulated by Yarnold[1] (following Adam and Jessop[2]) to explain his results on the hysteresis of the angles of contact of the surfaces of mercury indexes moving in glass tubes and of the surface of mercury against steel balls. Our results differ from his in that, among other respects, they show angles of contact of less than 90°. Our value for the static angle of contact, about 135°, agrees with his.

The surface of the mercury in our experiments was cleaned by sucking off the dust and upper liquid. Our results were quite reproducible, but neither the wire nor the mercury were specially cleaned apart from forming a fresh surface on the mercury for each run of photographs, since the observations were not undertaken to investigate surface phenomena.

We are indebted to Mr. J. W. C. Gates of the Light Division of the National Physical Laboratory for advice and to Mr. G. F. Miller of the Mathematics

Use of a Gaseous Discharge as an Identifiable Radar Target

The use of gaseous discharges as generators of radio noise has been widely reported in the literature, and work in this field is in progress at this Laboratory. Due to the high conductivity of gaseous discharges at microwave frequencies, a major problem in the design of a 'noise source' is a suitable means of introducing the discharge plasma into the electromagnetic field of the radio transmission circuit to provide a reflexionless match. It is readily demonstrated that a sudden introduction of a gaseous discharge into the path of an electromagnetic wave will produce a large reflexion of the incident power, and this fact has been used to produce a variable reflector of radio-frequency energy, thus providing in effect a modulated radar target.

It can be shown that a standard fluorescent light tube operating from the 50 c./s. mains supply will reflect 3-cm. radio waves, the reflected signal having a 100-c./s. modulation. By placing such a tube at the focus of a parabolic cylinder, the total reflected signal is considerably increased due to the larger amount of energy being intercepted by the parabola, and depending on the condition of the discharge tube for its reflexion.

The mechanism of the process is interpreted simply as follows. Energy intercepted by the parabola is focused on to the discharge tube. If the plasma is present, then because it has a high conductivity it reflects most of the incident power, and a large signal is returned. If, however, the discharge is extinguished the reflexion of power is from the glass of the tube and is of much less magnitude. At intermediate levels the reflexion depends on the current in the discharge. It has been found that excellent square-wave modulated returned signals are obtained if the discharge tube is suitably driven, that is, if a square wave-form of current is produced through it.

It has been found equally effective to arrange a similar discharge tube along the axis of a paraboloid. In this case the position of the tube is not critical over most of its length, although when the end of the tube is near the focus the additional effect of the electrode acting as a reflector behind the portion of plasma at the focus appears to give an improved total reflexion.

Further experiments have also been carried out with a 'beehive' neon lamp. In this case, the effective portion of the discharge is the cathode glow, and it is thought that the mechanism in this case may be the opposite of the earlier example, with the metal structure in the lamp normally acting as the reflector but screened by the discharge when the lamp is switched on.

No marked polarization sensitivity was observed with the discharge tube placed along the axis of a paraboloidal reflector. In the case of the parabolic cylinder with the discharge tube on the line focus, a considerable increase in performance was obtained at 3 cm. wave-length, with the electric field perpendicular to the axis of the discharge tube.

The device is of use in adjusting continuous wave radar sets where some form of fluctuating target is required, and may possibly have applications in providing a means of identification for the usual corner reflector types of target used in association with pulse radar systems.

Non-isothermal Plasmas in the Rare Gases

Kenty[1] noticed, many years ago, the finite lapse of time occurring between the termination of current flow in a low-pressure discharge in argon and the occurrence of maximum visible intensity of the afterglow. He suggested that the latter was due largely to radiative electron-ion recombination, and that the time-lapse was necessary for the electron temperature to fall to a value comparable with the gas temperature when the afterglow intensity would have reached a maximum, since recombination would continually reduce the electron and ion density. Bayet[2] and others have noticed a similar phenomenon and attribute it to the same cause. Also, an analogous effect due to pickup, in the afterglow, of electron energy from a microwave beam has been elegantly demonstrated by Goldstein and his collaborators[3].

Bayet[2] suggests that effects due to metastable excited atoms may be ignored at sufficiently high pressures. Moreover, Biondi[4] has shown that increased afterglow ionization due to metastable atom collision processes would tend to increase with increasing pulse-length (up to a limiting pulse-length, set by the time required to establish a full metastable atom population); this is in contrast with our results (Fig. 1), which show a decreasing afterglow light peak at increasing pulse-lengths.

For some years we have observed these effects in the rare gases, and the purpose of the present communication is to present preliminary data which are consistent with the recombination mechanism and which enable a recombination coefficient to be estimated. In view of the current interest in recombination processes, summarized by Massey[5], any method capable of yielding results of potential value may be worth investigation.

We have worked mainly at 1 atmosphere pressure in cylinder neon and helium, with rectangular current-pulses of a few microseconds duration, in contrast with the damped-condenser discharges used by Bayet[2], Olsen and Huxford[6] and others which render afterglow results more difficult to interpret. In high-pressure discharges, for example in helium, where the electron-atom energy transfer may be effected rapidly, the heating of the gas may be so great that there is a finite rate of electron production in the afterglow. This may be demonstrated by the non-

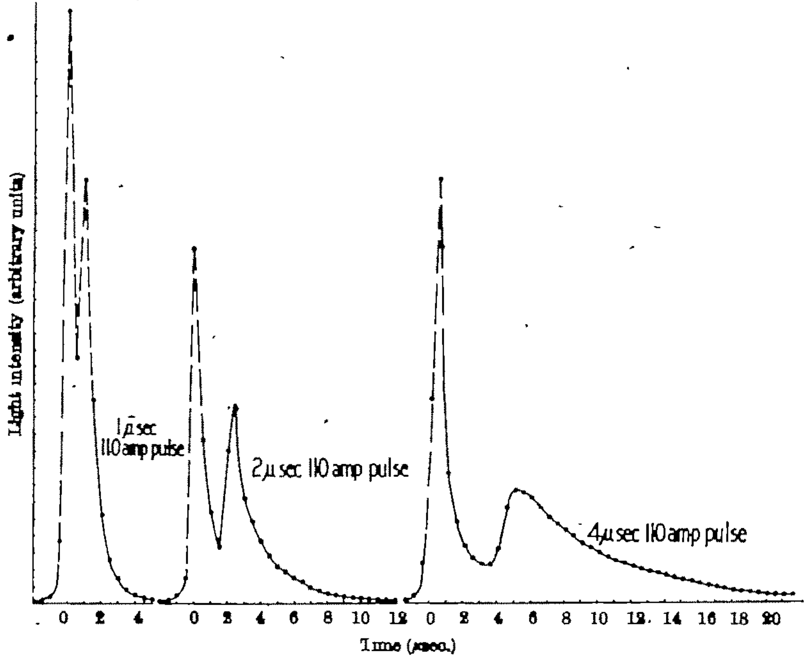

Fig. 1

linearity of the (light intensity)$^{-1/2}$ – time curve, which is necessarily linear for afterglows where radiative (two-body) recombination predominates, as Mohler[7] has shown. It is assumed, of course, that the recombination coefficient is constant throughout the time of observation. A recent discussion of the low-pressure work has been given by Massey and Burhop[8].

Our results show that the gas-heating effect is less, other things being equal, in neon than in helium, and that afterglows following pulses 1 microsec. long in neon show the requisite linear plot (Fig. 2*a*). Pulses of 4 microsec. (Fig. 2*b*) show non-linearity, also noticeable even in 0·8 microsec. discharges in helium. A recombination coefficient may be deduced if the electron density is known at any instant in the curve Fig. 2*a*. Measurements of the Stark effect have been made in this laboratory in helium and hydrogen; but for neon drift-current densities (averaged over the whole discharge channel, as a first approximation) give the electron density at 1 microsec. as $\sim 10^{14}$/c.c., and the resulting afterglow recombination coefficient as $\sim 10^{-10}$ cm.^{3}/sec. This value is appreciably less than the (dissociative) recombination coefficients ($\sim 10^{-6}$ cm.^{3}/sec.) obtained in ultra high-frequency studies[3], and may be attributable to dielectronic[5,6] or to electron-ion recombination.

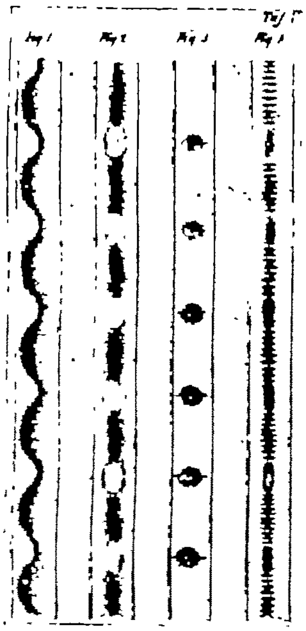
Powder Ridges in a Sound Field

I have found that the distance between powder ridges, formed on a flat surface in a sound field[1], increases rapidly with the size of the particle. Those who describe Kundt powder ridges make no mention of this fact. My results, however, appear to be a 'rediscovery' of some of Kundt's[2] original observations which, in view of their importance, are reproduced in the accompanying illustration. Whereas his fine striæ were formed with lycopodium spores of diameter 20 μ, the wider *Rippen* shown on their right consisted of fine sand grains of peak diameter c. 200 μ.

Such results can be explained in terms of Andrade's[3] vortex theory (which has superseded Koenig's hydrodynamical theory) and may link up eventually with other studies in which there is relative oscillatory motion between viscous fluids and powders. Bagnold[4], for example, in his experiments on powder 'ripples, formed under oscillating water, found that the inter-ridge distances varied approximately as the square root of the diameter of the grains.

In my own observations, when there is more powder present, the ridges are wider and farther



apart, and this effect can be recognized also in Fig. 4 of the illustration; compare the eight ridges between the central two nodes with the eleven ridges between the bottom two nodes.

The above facts must also be important at higher frequencies, especially in ranges where the inter-ridge and internodal distances may become comparable to one another. It is interesting to note that Soellner and Bondy[5], working on the subject of coagulation by ultrasonics, found that the distances between 'nodal lines' were strongly influenced by the size of the particles.

Fluorescence of Naphthoquinones

ATTEMPTS to devise a method for the identification of vitamin K_1 and other naphthoquinones by filter-paper chromatography led to the chance observation that some of these compounds exhibit a characteristic fluorescence which can be used for their detection. 10 μgm. of vitamin K_1 was chromatographed in a 75 per cent (v/v) aqueous ethanol solution on Whatman No. 1 filter-paper impregnated with silicone. When the paper was dried and held before an ultra-violet lamp (3665 A.), an area of red fluorescence was seen at R_F 0·20. With prolonged exposure to the ultra-violet radiation (45–60 sec.), the red fluorescence changed irreversibly to an intense, green fluorescence which was stable for at least four months. When sprayed with alcoholic potassium hydroxide, the green fluorescence changed to an orange fluorescence.

Although necessary for proper separation of the substances, silicone-coated paper was not necessary for fluorescence. Spraying the chromatogram with alcoholic solutions of nickel chloride or ammonium iodide, substances that often quench fluorescence[1], had no effect.

Of nineteen alkyl, hydroxyl or chloro substituted 1,4-naphthoquinones observed on filter-paper, all fluoresced red. 1,4-Naphthoquinone itself had no obvious fluorescence, and neither 1,2-naphthoquinone nor its methyl derivatives fluoresced. None of the substances tested fluoresced in petroleum-ether or ethanol solutions, although some of the crystalline compounds in the solid state did. These observations suggest that substituted 1,4-naphthoquinones may react in the same way as those substances, tabulated by Pringsheim[1], some of which fluoresce only in the solid state, others in rigid media.

A detailed report of reversed-phase partition chromatography on filter paper of the naphthoquinones and their detection by fluorescence will be published elsewhere.

I thank Prof. Henrik Dam for his encouragement and support of this work.

Liquid-State Equation for Normal Paraffins

BASED on measurements of liquid density and of heats of vaporization of the normal paraffin hydrocarbons, a very simple relationship has been deduced that appears to be of general applicability to this family of chemical compounds. The equation is as follows:

$$\frac{\rho - \rho_c}{\rho_0 - \rho_c} = \left[\frac{(1 + \alpha T)(-E/V)}{(-E/V)_0}\right]^{2/4},$$

where ρ is liquid density at the temperature of measurement[1]; ρ_c is critical density[2]; ρ_0 is liquid density extrapolated to absolute zero[3]; $(-E/V)$ is cohesive-energy density of the liquid at the temperature of measurement[4]; $(-E/V)_0$ is cohesive-energy density of the liquid extrapolated to absolute zero; and α is a constant (= 0·00125 for the *n*-paraffins).

The above relationship has been applied to the normal paraffins at atmospheric pressure over a range of temperatures from − 190° to + 345° C., and over a range of molecular weights from 44 to 283. The standard percentage error for the 78 points is:

$$100 \left\{\frac{\Sigma\,[(y_{\text{calc.}} - y_{\text{obs.}})/y_{\text{obs.}}]^2}{n}\right\}^{1/2} = 0{\cdot}57 \text{ per cent},$$

where $y = \dfrac{\rho - \rho_c}{\rho_0 - \rho_c}$ and n is number of measurements.

Work is in progress to investigate a large number of non-polar liquids to determine whether or not they also conform to this simple equation. Compressibility data on the normal paraffin hydrocarbons are being taken for us by Arthur D. Little, Inc., of Cambridge, Mass., and a study by them of the compressibilities of other liquids is contemplated. At a later date this research will be extended to polar liquids in the hope that their behaviour also may be characterized by some modification of this relationship.

FORTHCOMING EVENTS

Monday August 23—Saturday, August 28

Comité International de Photobiologie (at Amsterdam).—Fourth International Congress.

Wednesday, August 25—Wednesday September 1

Midlands Society for Analytical Chemistry (at the University, Birmingham).—Symposium on "Analytical Chemistry".

APPOINTMENTS VACANT

Applications are invited for the following appointments on or before the dates mentioned:

Research Metallurgists or Physicists (2) (with a first- or second-class honours degree in metallurgy or physics, and several years postgraduate experience), one to work on casting and working of rare metals used in nuclear power reactors, and the other to work on the arc melting and welding of these metals—The Establishment Officer, Atomic Energy Research Establishment, Harwell, Berks, quoting 2/103/134 (August 27).

Assistant Experimental Officer (preferably with a degree) with the Agricultural Research Council, Unit of Biometrical Genetics attached to the Department of Genetics in the University of Birmingham, for genetical work on fungi—The Secretary, Agricultural Research Council, 15 Regent Street, London, S.W.1 (August 28).

Chemist (with some knowledge of bacteriology, biochemistry, or the chemistry of soils or sewage) in the Chief Engineer's Department at London Headquarters, to study the effects on rivers of power station operations—The Director of Establishments, British Electricity Authority, Winsley Street, London, W.1, quoting NAT/499 (August 28)

Principal Scientific Officer (with an honours degree in science or civil engineering and a knowledge of applied mathematics and physics, and preferably with experience in the application of soil mechanics to civil engineering design and construction), with the Air Ministry at Wellesbourne Mountford, Warwickshire, for work on soil mechanics—The Ministry of Labour and National Service, Technical and Scientific Register (K), 26 King Street, London, S.W.1 (August 28).

Lecturer (with an honours degree and a knowledge of advanced physical metallurgy, and an interest in X-ray metallography) in the Department of Metallurgy; and a Lecturer in Dental Bacteriology—The Registrar, The University, Liverpool (September 1).

Lecturer (with special qualifications in plant physiology) in Botany—The Secretary, University of Durham, 38 North Bailey, Durham (September 1).

Microanalyst in the School of Chemistry—The Registrar, The University, Leeds (September 1).

Assistant Lecturer (with an honours or special degree in geography) in Geography—The Secretary, Bedford College (University of London), Regent's Park, London, N.W.1 (September 6).

Lecturer (Grade II) in the Department of Mathematics, at University College, Ibadan, Nigeria—The Secretary, Inter-University Council for Higher Education in the Colonies, 1 Gordon Square, London, W.C.1 (September 8).

Assistant Lecturer or Lecturer in Medical Biochemistry—The Registrar, The University, Leeds (September 13).

Chemist (with a first- or second-class honours degree with chemistry as the main subject, and preferably with a knowledge of the natural rubber industry), to operate the advisory service of the Chemical Division, to rubber-producing planters in Malaya, and to investigate problems arising from this work; and a Biochemist (with a first- or second-class honours degree, and able to produce evidence of sufficient postgraduate research experience on biochemical problems to carry out independent investigations), at the Rubber Research Institute of Malaya, Kuala Lumpur, to undertake research work on the biochemistry and enzymology of natural rubber latex, with particular reference to the naturally occurring non-rubber substances—The Secretary, London Advisory Committee for Rubber Research (Ceylon and Malaya), Imperial Institute, London, S.W.7 (September 13).

Leverhulme Fellow and Lecturer (with considerable experience of research work in nuclear physics, and preferably between the ages of 26 and 35 years) in the Department of Physics—The Registrar, The University, Liverpool (October 16)

Aerodynamicists and Aeronautical Engineers (with a first- or second-class honours degree or equivalent in mathematics, physics or engineering, and preferably with research or experimental experience of aircraft problems (Ref. A.215/54A); and Electrical Engineers (with a first- or second-class honours degree or equivalent in electrical engineering, and experimental or research experience in light electrical or electronic fields) (Ref. D 420/54A), at Ministry of Supply Research and Development Establishments, mainly in southern England—The Ministry of Labour and National Service, Technical and Scientific Register (K), 26 King Street, London, S.W 1, quoting appropriate Ref No

Chemist, Scientific Officer or Senior Scientific Officer grade, to work on new problems arising from the genetics of (1) plant pigments and (2) enzymes in high plants and fungi—The Secretary, John Innes Horticultural Institution, Bayfordbury, Hertford, Herts.

Experimental Officer (with qualifications equivalent to a pass degree in pure or applied science, and ability to prepare articles describing scientific and technical work in a simple and attractive manner, and preferably with experience in technical writing for industry or in a technical information service), in the Headquarters Office of the Department of Scientific and Industrial Research, for publicity work—The Ministry of Labour and National Service, Technical and Scientific Register (K), 26 King Street, London, S.W.1, quoting A 207/54A.

Lecturer in Agricultural Science, including Chemistry, at Winmarleigh Hall, near Garstang—The Principal Agricultural Officer, Lancashire County Institute of Agriculture, Hutton, Preston.

Lecturer (preferably university graduate in science with honours in zoology) in Economic Entomology, at Massey Agricultural College (University of New Zealand)—The Secretary, Association of Universities of the British Commonwealth, 5 Gordon Square, London, W C 1.

Physical Chemist or Physicist (with some experience in research) in the Department of Chemical Engineering, to undertake research on the hydrogen–oxygen fuel cell—The Secretary, Department of Chemical Engineering, University of Cambridge, Tennis Court Road, Cambridge.

Plant Physiologist, and an Agronomist (with good honours degrees), in the Research Division of the Ministry of Agriculture, Sudan Government—The Sudan Agency in London, Sudan House, Cleveland Row, St. James's, London, S.W 1

Professor of Organic Chemistry—The Registrar, University of Adelaide, Adelaide, South Australia.

Regional Trials Officer (with a degree in botany or agriculture or equivalent qualification, and with practical experience in crop production), for work possibly in Hampshire—The Secretary, National Institute of Agricultural Botany, Huntingdon Road, Cambridge

Research Assistant (graduate in agricultural chemistry or chemistry), to undertake work in the field of plant nutrition; and a Demonstrator (graduate in agricultural chemistry or chemistry) in the Department of Agricultural Sciences—The Registrar, The University, Nottingham.

Research Assistant in the Department of Aerodynamics, to assist in research on freon as a medium for high speed wind tunnels—The Recorder, College of Aeronautics, Cranfield, Bletchley.

Research Scholar (with a degree in chemistry) in the Department of Applied Chemistry, to work on the constitution of tars—The Head of the Department of Applied Chemistry, Northampton Polytechnic, St. John Street, London, E.C.1.

Senior Biochemical Technician (Fellow of the Institute of Medical Laboratory Technology, or with a degree in chemistry or equivalent qualification) in the Department of Pathology, to be responsible for routine biochemical investigations—The Hospital Secretary, Canadian Red Cross Memorial Hospital, Taplow, near Maidenhead.

Statistician (with a good degree in mathematics or statistics and some postgraduate training in statistics, and preferably a diploma in statistics, with experience of, or training in, statistical methods as applied to agricultural field experiments), in the Department of Agriculture, Kenya, to advise on the design of field and other experiments conducted by the Department including sampling, investigations and surveys, and to assist in the statistical analysis of results—The Director of Recruitment (Colonial Service), Colonial Office, Sanctuary Buildings, Great Smith Street, London, S.W.1, quoting CDE.63/7/03.

TECHNICAL COLLEGES AND INDUSTRY

AT the Conference on Technical Colleges and Industry in Britain arranged by the Federation of British Industries, and held during May 5–7 (see *Nature*, July 31, p. 210), Sir Arthur Smout strongly criticized the present position of technical education and its subordination to local and party politics. In particular, he proposed the establishment of a Technical College Grants Committee comparable with the University Grants Committee, so as to free the administration and finance of at least the major technical colleges from such influence; this indeed might help to secure the essential academic independence and properly constituted governing bodies for which Dr. P. F. R. Venables pleaded at the North of England Educational Conference held in January. To be successful, however, it might also require the responsibility for technical education, except in so far as training for unskilled or semi-skilled occupations is concerned, to be removed from the Ministry of Education.

Sir Arthur Smout's forthright comments on salary-scales support arguments advanced by representatives of the teaching staff in the technical colleges, and the impossibility of drawing any sharp distinction between technical and technological education is a further reason for some such change. The expansion of technological education in the five centres proposed by the Government will still make it necessary to continue the provision made in the remaining university departments of technology and in the technical colleges. Dr. Lincoln Gorden, in addressing the Union of Lancashire and Cheshire Institutes last October, for example, expressed the view that the expansion of existing university departments, the development of existing colleges of technology and the establishment of one or more independent institutions, along the lines of the Massachusetts Institute of Technology, even if pushed to the furthest practicable limits, would not surpass the growing needs. Even if the useful suggestion made by Dr. Venables at the Federation of British Industries Conference were adopted and the use of the term 'technological education' be limited to postgraduate education, the overlap between technical and technological education—and indeed between the functions of the universities and the technical colleges—would not be eliminated; nor indeed may it be desirable that it should be.

Any body responsible for technical education would accordingly necessarily be concerned with technological education, and it should be considered whether the responsibility for both could not be effectively discharged by the technological education sub-committee of the University Grants Committee. Such a step might have the advantage of encouraging parity of status and esteem between the technical colleges and university departments. It should be noted that in arguing again for the establishment of a technological university Lord Cherwell, in his Messel Memorial Lecture on July 14, once more referred to the lack of esteem which careers in science and technology still receive in many grammar schools and public schools and universities. That contention, however, finds no support in the discussion on higher technological education at the Congress of the Universities of the Commonwealth at Cambridge last year, where it was fully recognized that the universities should play a part in the production of technologists and that technological education must take its place with the other and older disciplines. Admittedly, to do so, universities require a much closer knowledge of the nature and purpose of industry and of the needs of industry in respect of personnel. Moreover, it was recognized there that in technological education we are concerned with the acquisition of knowledge for the purpose of achieving industrial or commercial objectives, rather than, as in a scientific education, primarily with the acquisition of knowledge and the mastery of objectives.

Nevertheless, whether in the university department or in the technical college, the emphasis must be on education, as distinct from training. It is the mastery of theoretical knowledge which later can be combined with skill and experience in applying it to immediate ends; and the training in that process is a function which must largely depend on the co-operation of industry itself. For that reason, an alternative to Sir Arthur Smout's suggestion deserves consideration, particularly in view of the close dependence of industrial development and technological advance on both technical and technological education.

The increasing interest now being taken in the educational responsibilities of the research associations is only one indication of the readiness of industry to associate itself with technical education and training, and has already led to the suggestion that the Advisory Council for Scientific Policy might be the appropriate body for watching over the development of the technical colleges in the national interest. To make that body responsible for the distribution of grants for technological and technical education would involve, however, a major disturbance to the existing arrangements. What is really needed is some sufficiently authoritative body which is competent to formulate a real policy and see that it is implemented, and that the procrastination of the Ministry of Education is no longer tolerated.

Effective means are required of fostering co-operation between the universities, the technical colleges, the professional institutions, the local education authorities and industry and commerce, of formulating policy in place of piecemeal decisions and of implementing it in a way that wins consent. An overall plan for technological and technical education is required to avoid waste of resources and to command approval of the sacrifices which will be involved; but it is equally true that no such plan will work effectively without understanding and co-operation at all levels, local as well as regional. Now that Mr. R. A. Butler has lifted the veil on the Government's intentions, much constructive thinking is required as to the best means of dealing with the many complex issues that arise within the broad framework laid down. Three specific points appea to require early attention, and they are inter-related the extent to which the training of technicians an technologists can be carried out in industry itself the balance between research and teaching, in th universities and in the expanded colleges of technology; and the relation between supply an demand for scientists and other graduates. All i turn react on a fourth problem, namely, the suppl and distribution of trained man-power available fo such developments, quite apart from the question c finance and material resources, and disregarding th situation in regard to technical colleges disclosed b the twelfth report of the Estimates Committee fo the session 1952–53 last autumn.

It is to be regretted that the Parliamentary an Scientific Committee has seen fit to publish th memorandum* on higher technological educatio which it had already drafted when the Chancello made his statement on July 13, instead of examinin carefully the implications of that statement an making constructive proposals to deal with thes issues. As it stands, the memorandum is essentiall a summary of known views on the expansion o higher technological education, which indicates som of the essential factors but makes no positive con tribution for the solution of any of the intricat problems involved. This is particularly true i respect of the reconciliation of clashing interest where the Committee might have been expected t be most helpful. Indeed, the memorandum lacks an appreciation of the fact that the improvement o technological and technical education, urgent an important as it is, will demand sacrifices elsewhere To be effective, the developments now proposed b the Government will make heavy demands on resources, apart from money, which are already scarce—good teachers, buildings and equipment. At the intake end they affect the redistribution o students over courses; to ensure that the proposed new facilities are fully used when available may entail an educational campaign in the schools and elsewhere, as a recent report from the Advisory Council on Scientific Policy indicated.

It may be necessary, as Mr. F. H. Perkins suggested in a paper before the recent meeting of the Associations of Technical Institutions and of their Principals, to divert a larger proportion of those who have taken classics and the arts courses at schoo into scientific courses, to place in the technical colleges more of the 'patient plodders' of the present university population, who are regarded by Mr. J. F. Wolfenden as unsuited for a university education and who might develop better in such courses, and to adopt improved methods of selecting and training those who seek a career in science and technology but did not receive a university education. The response to such measures will, however, depend in part on the readiness with which industry absorbs the increased output of scientists and technologists. Any considerable amount of unemployment among particular types of technologists or scientists when scientific establishments, both government and industrial, cease to expand, and new scientists and technologists are wanted chiefly to replace losses through retirement and like causes, could adversely affect the numbers leaving school prepared to take up careers in applied science.

---

* Parliamentary and Scientific Committee. Memorandum on Higher Technological Education. Pp 16. (London: Parliamentary and Scientific Committee, 1954.) 2s.

This aspect of the problem merits much more areful examination than it has yet received. Until much more reliable evidence is available on prospective demand, it would be wise to follow Sir Philip Morris's advice and concentrate on ensuring that alent of varying kinds is given the maximum opporunity to develop according to its bent. That is not merely an argument for a variety of institutions for higher technological education: it is equally a reason for promoting much more effective co-operation between technical colleges, universities, professional institutions, industry and commerce. The establishment of a common field of interest in common problems and common objectives, and a recognition by all concerned that others have their indispensable contribution to make in achieving the desired objectives are the first steps. The Federation of British Industries and the Department of Scientific and Industrial Research have already, through their conferences, done something in this direction; but more is required. On industry, on the universities and on the technical colleges especially, lies the responsibility for seeking urgently to devise appropriate means for closer and more intimate relations while the Government is formulating policy and the means for securing the overall co-ordination of the distribution of resources.

The balance of research and teaching obviously turns in part on this question of supply and demand, but still more on the extent to which we succeed in introducing more breadth into the teaching of science and technology, both at the universities and the technical colleges. It is not a multiplication of highly trained specialists that the nation needs, least of all young men and women who are the creatures of their skills rather than the masters of them. Industry and society need rather more men and women who have been equipped by a broad and humane education with the knowledge, skill and adaptability to seize the opportunities of development that scientific and technical advances offer to industry.

Much that Prof. E. C. Stoner said in a lecture at Leeds on the balance of teaching and research in universities is highly relevant to the question of research in technological colleges. If it is true that more opportunities are desirable for the teaching staff to engage in both research and consulting work, and for a technical college to encourage, in co-operation with industry, a wide range of applied research of high quality, it is not the students only, even postgraduate students, who will profit by engaging in such research. For the good of the community and of themselves, many such would be better occupied otherwise, and this factor should be kept in mind in determining the pattern of expenditure at technical colleges and at universities.

Prof. Stoner estimates university expenditure on research as about 35 per cent of the total, the remainder being broadly on undergraduate teaching. It is arguable whether it should be allowed to run anything like as high in the technical colleges, even if it is admitted that costly large-scale projects in applied research which, as Prof. Stoner points out, would be out of place in the universities, might fittingly be encouraged in the larger colleges of technology where these colleges are suitable equipped. Even so, it is probably true that such projects are more appropriately and conveniently, if not more effectively, carried out by the industries themselves or by research associations. Indeed, the danger of distorting the work and structure of the departments concerned and the unbalancing of their relationship with the rest of the college may well be even greater than in the department of technology of a university, and all the more if the technical colleges show a like caution in accepting candidates for postgraduate research to that which Prof. Stoner suggests for universities, and limit their choice to those who show promise of powers to advance their chosen field farther not simply as assistants but as originators of new lines of thought and investigation.

Any such policy implies a more balanced view of their responsibilities in the development of the young men and women whom the technical colleges educate, such as Sir Charles Morris urged on the universities in his Joseph Payne Memorial Lectures. Such a balanced view is necessary to secure the co-operation, which is so important, between industry, the universities and technical colleges. It could be decisive in determining the distribution of trained man-power available for the development of technological education, whether in the universities or in the technical colleges.

On this last issue the memorandum of the Parliamentary and Scientific Committee seems strangely unrealistic. The memorandum suggests that the universities could increase their output of scientists and technologists without increasing the present total number of students, without detriment to present standards and indeed with some increase in breadth of studies. It nowhere recognizes fully that such a change in balance would make quite appreciable demands for staff as well as buildings and equipment, and would be in competition with the expansion of the colleges of technology. Nevertheless, the report contemplates the expansion ultimately of some twenty such colleges, though admittedly of only "a few" at first, and it pursues the chimera of a new award; 'bachelor of technology' is suggested, without pausing to consider where the teaching staff, for example, is to be obtained, or at what sacrifice elsewhere.

Teaching staff of high standard, academic autonomy, adequate equipment and buildings are the conditions that must be secured before any new award can even begin to win the prestige that will give it any value, and the Committee passes too lightly over the question of co-operation and the means by which it is to be achieved. Its memorandum gives little hope that any serious attempt is being made to help Parliament to understand clearly the price which has to be paid for the expansion of technological and technical education, or the necessity of regarding such expansion and developments as part of a concerted policy for the promotion of education at all levels, from the university to the schools. A realistic and comprehensive view, however, is essential, both for the formulation of policy and the wise allocation of resources as between the universities, including their technological departments, the colleges of technology, technical colleges and the schools. If the main responsibility in that respect lies on the Government, the implementation of that policy depends on the co-operation and goodwill of industry and commerce, the professional institutions, and the local authorities, as well as of the universities and colleges directly concerned. While the Government has still a long way to go in elaborating policy and allocating resources reasonably, there is much that could be done in the meantime by all such bodies to assess needs and priorities and ways and means of meeting them locally, and in devising appropriate forms of co-operation. Finally, it will be necessary to educate public opinion to hold a higher level of general esteem for careers in technology and to accept the fact that sacrifices will be required in an expansion so vital for the industrial and economic future of Britain.

ORGANIC CHEMICALS

Dictionary of Organic Compounds

The Constitution and Physical and Chemical Properties of the Principal Carbon Compounds and their Derivatives, together with the relevant Literature References. Edited by Sir Ian Heilbron and H. M. Bunbury. Vol. 1: Abadole–Cytosine. Pp. xvi+654. Vol. 2: D.A.–Hystazarin. Pp. xvi+845. Vol. 3: Ibogaine–NW-Acid. Pp. xvi+838. Vol. 4: Obaculactone–Zymosterol. Pp. xvi+694. New and revised edition. (London: Eyre and Spottiswoode (Publishers), Ltd., 1953.) £28 the set.

"LET'S see what Heilbron says about it"; some such words and the rather worn appearance of all the volumes are oral and tacit tributes to the esteem in which the first edition of this work is held. When the original three volumes were published a few years before the Second World War it was planned to issue completely revised editions at convenient intervals. Circumstances ordained otherwise; although a new edition of the first volume appeared in 1943, the text of the other two remained unchanged, except for a slim supplement.

Although during the war years the direction of research was changed, it continued unabated, and in the post-war period the heavy task of revision was undertaken; the result of that labour is now represented by this new edition. The division into four volumes instead of three gives books which are less cumbersome to handle, and, by utilizing a somewhat larger area of the paper, more than two thousand five hundred new main entries have been incorporated with the addition of only ninety additional pages; indeed, in inches of shelf space, there is practicall no change. It is claimed that the literature up t the end of 1950 has been covered, and there ar occasional references up to 1953.

The subject of nomenclature is a difficult one, and n particular system has been followed in its entirety indeed, it is stated that that which is employe in the original publication has generally been give preference. The order in which substituents ar listed is different from that formerly used by th Chemical Society, and for convenience it is given i some detail in the introduction to each volume. T have adopted the current alphabetical order woul have incurred extensive revision and considerabl delay in publication, but it is to be hoped that i will be followed in future editions; the few rule are not difficult to learn, and there is then n need to search a list for the relative position o substituents.

The prefixes cyclo- and iso- are treated as integra parts of names. There is much in favour of thi action for the former, because it does not indicat isomerism; but with the latter it means that i comparing properties of, for example, butyl compounds, three are grouped together while the fourt is in another volume. In acyclic acids, the carboxy group is generally regarded as a substituent, so tha 2- and 11-hydroxypentadecanoic acids appear as 1- and 10-hydroxypentadecylic acids respectively; in contrast, 15-hydroxypentanoic acid is listed as 15-hydroxypentadecylic acid. It would seem preferable to adopt the latter numbering throughout so that the same numbers would be used irrespective of whether the name is trivial or systematic. As a minor point, there is lack of uniformity in naming the long-chain olefines—for example, nonene, decylene, tridecene, tetradecylene, octadecene.

For the monoethers of ethylene glycol, one is referred, for example, to 2-hydroxydiethyl ether and 2-hydroxyethyl butyl ether. Such compounds would be more neatly named on the lines of 2-ethoxyethyl alcohol or, even better, 2-ethoxyethanol; the esters of these ethers, for example, the acetates and phthalates, could be named accordingly and are, indeed, of sufficient importance to be listed individually. Such well-established names as carbromal and leptazol are not mentioned at all, the compounds being listed under their foreign names. Mepacrine is referred back to atebrin, and chloramphenicol appears in its own right.

The selection of data which can be quoted with full confidence is very difficult because of the many divergences in the literature. Prof. J. Timmermans, in his recent book on "Physico-chemical Constants", has surveyed some of the ground, and it is of interest to note that an ambitious plan is on foot in the United States to review and assess critically data for chemical compounds generally on the lines of the American Petroleum Institute's Research Project 44, dealing with hydrocarbons.

In this "Dictionary", alternative data which cannot be rejected forthwith are usually placed in brackets. For many hydrocarbons, work by the petroleum interests, both in Britain and in the United States, has reached the stage where some of such values can be discarded. For other types of compounds, there is also some room for improvement. Since 1930, there have been recorded several sets of values for density and refractive index of cyclohexylamine, reasonably concordant among themselves, but very appreciably different from those quoted. Again, There are several records of these two properties for di-*n*-butyl ether and *n*-butyl propionate, for both of which density at 0° C. alone is given, that for the latter compound dating from 1886. The preferred melting point for *m*-hydroxybenzaldehyde is evidently that of Jowett (1900), who later identified his product as *p*-hydroxyacetophenone; there is ample corroboration of the bracketed value.

Generous use of cross-references avoids duplication of entries with corresponding danger of discrepancies. This has, however, occurred with some of the sulpha drugs and their acetyl derivatives; some of these are also listed as the *p*-aminobenzenesulphonyl derivatives of the heterocyclic amines with melting points which differ by up to 8 deg. C.

A particular feature is the inclusion of a large number of organic compounds of natural origin; but asarinin, stevioside (of interest for its sweet taste) and dihydronorguaiaretic acid (NDGA) are three uch products which appear to have escaped the net. Di*tert*-amyl peroxide is listed (under A, contrary o the declared naming of 'double' derivatives) but not the commercially important *tert*-butyl compound.

These various observations must not be taken to mply that the "Dictionary" is bristling with inaccuracies and omissions. They merely show that the editors of books of this kind can never sit back with the comfortable feeling that their work is completely satisfactory; there is always some dusting and polishing to be done. The reviewer will continue to use the "Dictionary", as a first source of information about compounds, except those newly described, with the assurance that, more frequently than not, the search will not be in vain. B. A. ELLIS

LINEAR OPERATORS

Linear Analysis

Measure and Integral, Banach and Hilbert Space, Linear Integral Equations. By Prof. Adriaan Cornelis Zaanen. (Bibliotheca Mathematica: a Series of Monographs on Pure and Applied Mathematics. Volume 2.) Pp. vii+602. (Amsterdam: North-Holland Publishing Company; New York: Interscience Publishers, Inc., 1953.) 38 florins; 76*s*.

Linear Operators

Spectral Theory and Some Other Applications. By Dr. Richard G. Cooke. Pp. xii+454. (London: Macmillan and Co., Ltd.; New York: St. Martin's Press, Inc., 1953.) 52*s*. 6*d*. net.

THE general theory of linear operators is mainly a creation of the present century; it originated in the work of Hilbert and Riesz on the theory of integral equations and its extensions, and assumed its modern abstract form in the 1920's in the hands of Banach, von Neumann and Stone. The past twenty-five years have witnessed its growth into the wide-ranging subject known to-day as functional analysis, which may be described as the application of the methods of topological algebra to problems in the theory of functions.

Each of these two books is concerned with certain aspects of this now enormous field. They have a small amount of basic material in common; but their aims are very different. Prof. A. C. Zaanen is mainly interested in topics related to the classical theory of linear integral equations, whereas Dr. R. G. Cooke's principal aim is to acquaint his readers with the spectral theory of self-adjoint linear operators in Hilbert space.

Prof. Zaanen's book begins with an account of the Lebesgue integral on a general measure space, and continues with a detailed discussion, not only of the L_p spaces but also of the less familiar Orlicz spaces. We next find a description of the structure of Banach spaces and Hilbert space, and an outline of the theory of bounded linear operators, including the Banach–Steinhaus theorem and the closed graph theorem. In order to avoid using the axiom of choice, Prof. Zaanen does not prove the Hahn–Banach theorem on the existence of linear functionals in its most general form, but he shows that it can often be dispensed with; for example, the whole Riesz–Schauder theory of compact (or completely continuous) linear operators is obtained without appealing to it. The Dunford spectral theory is outlined; but there is no account of the spectral theory of general self-adjoint operators in Hilbert space. The applications of the Riesz–Schauder theory to integral equations receive very thorough treatment, the Fredholm theory is extended to a wider class of integral operators than usual (those that are completely of finite double norm), and a very detailed discussion is given of various classes of symmetrizable integral operators.

The book is too long and detailed to be suitable as a first introduction to the subject; but it will be an indispensable work of reference for these aspects of functional analysis. Particularly welcome are the numerous illustrative examples, to most of which are attached either hints for solution or references to the original literature.

Dr. Cooke's book is a successor to his "Infinite Matrices and Sequence Spaces", published in 1950. The first five chapters contain an introduction to Hilbert space and its applications in quantum mechanics, and a very full account of the spectral theorem for hypermaximal (or self-adjoint) linear operators, both bounded and unbounded. A number of the known proofs of the theorem are given in detail. The remaining two chapters deal with topics having little direct connexion with the first part of the book. Chapter 6, on projective convergence in matrix spaces and rings, is a pendant to the author's earlier book, and describes some recent investigations on linear operators in sequence spaces. Chapter 7 is on Banach algebras; it contains a useful account of the Gelfand representation of a commutative Banach algebra by functions on the space of maximal ideals, and its applications to the proof of Wiener's theorem on the closure of translations and his Tauberian theorem. Other topics included are the spectacular and powerful Weierstrass–Stone theorem on uniform approximation to continuous functions, the theory of Radon measures, defined as linear functionals on a class of continuous functions, and an application of the theory of Banach algebras with an involution to the proof of Bochner's theorem on positive definite functions.

Much of the material in this book has hitherto been scattered in the periodical literature, some of it being available only in Russian, and the author has performed a useful service in collecting it together. Dr. Cooke writes as an analyst for analysts; the emphasis throughout is on analytic techniques and applications, and the algebraic structures tend to remain in the background. F. SMITHIES

British Journal of Applied Physics

Edited by Dr. H. R. Lang. Vol. 4, 1953, and Supplement No. 2: "Static Electrification"—a Symposium held by the Institute of Physics in London on 25, 26 and 27 March, 1953. Pp. vi+391+(supplement iv+104). (London: Institute of Physics, 1953.) £5 11*s*.

Vol. 4 of the *Journal of Applied Physics*, the monthly journal of the Institute of Physics, is the bound volume for 1953 and contains fifteen special articles and reports, three conference reports and sixty-five original contributions, in addition to a supplement in which are reprinted the proceedings of a conference on static electrification held at Bedford College, London, during March 25–27, 1953. In the three conference reports the proceedings are summarized of the conference on electron microscopy in Bristol during September 1952, the fortieth anniversary celebrations of the discovery of X-ray diffraction in London during October 1952 and the conference on the optical and electron-microscopical properties of textile fibres in Manchester during October 1952. The special articles include the address of Sir John Cockcroft, given at the Bournemouth convention of the Institute on May 29, 1953, dealing with recent advances in nuclear physics; the application of digital computing techniques to physics, by R. A. Brooker; recent developments in magnets and magnetism, by Prof. W. Sucksmith; scientific applications of high-speed rotation, by Prof. P. B. Moon; and scintillation counting and its medical applications, by Prof. W. V. Mayneord.

The supplement on static electrification, after a brief foreword by N. Clarke, the deputy secretary of the Institute and conference secretary, contains the opening address, delivered by Prof. F. A. Vick, in which a brief but clear outline of the theory of contact electrification is given. This is followed by twenty-three papers, with discussions, which are grouped under the four headings of general principles, and useful applications, of generation and dissipation of static electricity, electrostatic machines and harmful static electrification.

The editor and advisory committee must again be congratulated for the excellence of production of Vol. 4 and for the high general standard they maintain in the *Journal*.

A Text-Book of Metallurgy

By A. R. Bailey. Pp. viii+560. (London: Macmillan and Co., Ltd., 1954.) 30*s*. net.

In these days any attempt to write a general text-book on an applied science such as metallurgy is fraught with difficulties arising primarily from the continued rapid expansion of the technology and the further elucidation of the underlying scientific principles. In this case the author has succeeded in producing a very readable survey of most branches of metallurgy without neglecting many recent important developments.

The book falls broadly into three sections—physical metallurgy; ore dressing and metal extraction; fabrication and testing—which are encompassed in just over five hundred pages of text, so it is obvious that most subjects are considered only at an elementary level. Nevertheless, the treatment of the subject-matter is balanced and provides for the first-year degree student a general vista of the subject which is so desirable before he proceeds to more advanced studies. The book's role as a stepping-stone is enhanced by the excellent additional reading lists at the end of each chapter, which are thoroughly u to date. The illustrations are profuse and of goo quality; Fig. 274 is unfortunately upside down, s that the liquid metal apparently defies gravity. Th examination questions set by various examining bodie are a useful ancillary. The book is a commendabl addition to metallurgical literature and deserves to b read by many students. R. W. K. Honeycombe

Cathodic Protection of Pipelines and Storage Tank

By V. A. Pritula. Pp. vi+160. (London: H.M.S.O 1953.) 10*s*. net.

This book is a translation from the Russian, it publication being arranged by the Departmen of Scientific and Industrial Research, which recommends it as a practical manual and a text-book o the subject of cathodic protection of pipelines an storage tanks. It was originally published in 1950 by th Chief Petroleum Marketing Organization of the Russia Ministry of the Petroleum Industry and appeared in series of petroleum and mined-fuel literature.

The purpose of the book is to describe the investigation of the problems of electrical protection o metallic pipelines and storage tanks against underground corrosion. The various types of corrosion ar specified, and the fundamentals of the new method o cathodic protection are outlined. The basic principl is to protect the entire surface of the equipmen cathodically by connecting it to a source of d.c potential and forming an electric circuit the anod of which is a specially earthed electrode which becomes corroded during the process. The anode i usually made of scrap metal.

Full details of the investigation, design and operating conditions for the practical use of cathodic protection, together with explanatory circuits and diagrams and much numerical data, are given in the twelve chapters and two appendixes in the volume. The bibliography refers only to what appear to be Russian periodicals.

Theory of Superconductivity

By M. von Laue. (Translated by Lothar Meyer and William Band.) Pp. x+140. (New York: Academic Press, Inc.; London: Academic Books, Ltd., 1952.) 4 dollars.

The title of this book is somewhat misleading, since it is not so much a general account of the phenomenon of superconductivity as a comprehensive development of the ideas, originally due to F. and H. London, concerning the nature of the equations governing the supercurrent. In view of the very slender experimental evidence in support of the exact form of the London equations, it may perhaps be questioned whether it is in the best interest of the subject to regard them with such confidence in their correctness as Prof. M. von Laue displays. If they eventually are shown to be correct, he will undoubtedly have performed a valuable service in investigating so fully their mathematical and physical consequences; but there is a genuine danger that his authority, and that of other theoreticians, will serve to stifle the critical experimental investigation which this branch of the subject urgently demands, and cause the London equations to be treated with more respect than any tentative theory deserves. It is, no doubt, an advantage to English-speaking readers to have this book available in translation; but since its main interest lies in the mathematics, it cannot be supposed that the advantage is very great. A. B. Pippard

THE PHYSICS OF THE SOLID STATE

FOLLOWING the meeting of the General Assembly of the International Union of Physics in London in July, a number of scientific meetings were held to take advantage of the presence in Great Britain of the delegates to the Assembly from overseas. Of these, two were about the physics of the solid state; one at Bristol sponsored by the Union and with an attendance of about three hundred and fifty had as its subject "Defects in Crystalline Solids", and one directly afterwards in the Department of Metallurgy of the University of Birmingham was on the "Mechanical Effects of Dislocations in Crystals".

The idea of the Bristol Conference was to include two subjects which at first sight appear widely separated, but which are becoming more closely related. The first of these subjects was dislocations in their more chemical aspects. It was desired, for example, to discuss their relation to vacant lattice sites and to diffusion; their role in crystal growth and in accelerating precipitation and also their influence on semi-conductors. But questions concerned with their movement and with the mechanism of the formation of slip bands were reserved for the Birmingham Conference. The second subject was the use of electron and nuclear spin resonance in the investigation of defects in solids. On this subject an impressive series of papers was given by Kittel, Kip, Bloembergen, Slichter and others from the United States and also by representatives from Great Britain.

In addition to the X-ray camera, the optical and electron microscopes, radioactive tracers and all the other techniques used in this field, microwaves have quite suddenly, in the past two or three years, become a tool of major importance. Thus, for example, the electric quadrupole moment of the nucleus makes it possible in suitable cases to determine the value of the gradient of the electric field (dE/dx) at any lattice point where the nucleus is situated. In a pure crystalline substance of cubic symmetry this is, of course, zero, but not in an alloy. Dr. Bloembergen, of Harvard, outlined how in dilute solutions of zinc in copper it is possible to evaluate the contribution to dE/dx separately from the nearest, the next nearest neighbours and so on. Such measurements promise to be of the greatest importance for understanding the forces between atoms in alloys. It has also been possible to measure the density of dislocations in cold-worked substances by their effect on the breadth of the resonance line.

Another important effect is that described by Slichter; the broadening of the magnetic resonance line due to a nuclear spin is much reduced if the atom changes its position in a time small compared with the period of the radiation used. This is because the broadening is mainly due to the interaction with the spins of neighbouring nuclei; and it is, so to speak, averaged out by the movement of the nucleus from one lattice point to another. By this method it has proved possible to measure coefficients of self-diffusion in solids without the help of radioactive isotopes, and results were quoted for the alkali metals.

With regard to the rest of the Conference, there were many papers on the effect of irradiation by fast neutrons and other fast particles, and their effect in producing defects such as F-centres. Prof. R. Hilsch, from Göttingen, spoke on the occurrence of a high concentration of defects in metallic and non-metallic films evaporated at the temperature of liquid helium, and the surprising amount of recovery which takes place when the temperature is raised to that of liquid hydrogen. There was much discussion of networks of dislocations in solids, which can be made visible by the formation of various types of precipitate along them. In fact, the role of dislocations in accelerating precipitation seems firmly established, though the exact mechanism by which it does so is less clear. They apparently act as centres for the nucleation of precipitates.

But perhaps one of the most important properties of dislocations which has recently been brought to light is the ease with which foreign atoms can move along them. As explained by Prof. R. Smoluchowski (Pittsburgh) and by Turnbull (General Electric Schenectady), the activation energy for diffusion along a dislocation is the same as that for diffusion in a grain boundary at which there is a large change in the orientation of the crystal planes. Boundaries at which the change of orientation is small can, as is well known, be analysed into rows of dislocations, and for these the rate of diffusion of radioactive isotopes or of impurities depends on the direction. Thus for a boundary which consists of a row of edge dislocations, the diffusion is fast in the direction in which they lie, and slow when they have to move from one dislocation to another.

It is clear that the ease with which foreign atoms diffuse along grain boundaries and dislocations, which can at the same time move about, plays a large part in allowing precipitation and age-hardening at temperatures at which normal volume diffusion would not be possible. Dr. J. H. Hollomon suggested that the formation in aluminium–copper alloys of the plates of mono-molecular thickness known as Preston–Guinier zones is due to dislocations moving through the grains and sweeping up the copper, which quickly diffuses along the dislocation to be left behind in one of these plates. Since most energy is released by this process when the plates form on the (100) planes, this is the direction in which the dislocations move.

On the subject of crystal growth, Hollomon showed a film of the growth of cadmium iodide crystals suggesting that in the early stages these crystals might well grow without the help of screw dislocations, but that the dislocations on which the well-known spirals are centred are formed when two crystals the orientations of which do not quite fit join together. Dr. J. W. Mitchell (Bristol), who was responsible for the scientific and social organization of the Conference, showed a series of slides which demonstrated that silver halide grains in emulsions owe their triangular or hexagonal shape with the (111) faces exposed to a particularly stable arrangement of three dislocations meeting in a point and lying parallel to the flat surfaces of the crystal.

The papers given at this Conference will be published by the Physical Society.

Turning now to the Conference at Birmingham, organized by Prof. A. H. Cottrell, this dealt in the main with the mechanism of work-hardening and formation of slip lines, and with the production of vacant lattice sites by moving dislocations. There seems now to be a fair amount of agreement about many features of this process. For example, it is generally assumed that slip has its origin in Frank–Read sources; it is not now believed that the speed of moving dislocations is great enough for important dynamic effects to occur involving the kinetic energy of a dislocation, and Dr. J. D. Eshelby (Birmingham) presented a new paper on this point. Everyone was agreed on the importance of the fine slip lines (about 10 μ long and around 100 A. high) first observed on many metals by Wilsdorf (Pretoria), and that one of the main mechanisms of work-hardening is the elastic interaction between the dislocations which produce this fine slip; this is very much as envisaged in the paper which G. I. Taylor published in 1934. There was much less agreement on the cause of the slip bands which can be seen under the optical microscope and which are much longer. The case of alpha-brass, however, is particularly instructive, and was discussed by Dr. J. C. Fisher (General Electric, Schenectady). Here no fine slip was observed by Wilsdorf, and single crystals of this alloy show very little hardening, at least so long as slip is confined to one set of planes. This shows that the dislocations on neighbouring coarse slip lines are too far away from each other to interact strongly. Fisher's explanation of the absence of fine slip and the conspicuous coarse slip in this alloy is that there is a certain amount of short-range order, which has to be destroyed over a plane when a dislocation moves across it and which therefore hinders its motion. Once a dislocation has moved along a plane, however, others from the same source can follow it under the influence of a much lower stress.

Another mechanism of hardening and also of resistance to flow in annealed metals is the work which must be done to push dislocations past screw dislocations which cut the slip plane. When this occurs, a 'jog' is produced in a dislocation line, and this has a certain energy. This mechanism of resistance to flow is expected, like the resistance due to locking by impurities, to show a strong dependence on temperature; that due to the elastic interaction of dislocations (G. I. Taylor's mechanism) is not. Cottrell showed some curves giving as a function of temperature σ/G for copper work-hardened at the temperature of liquid air; σ is here the flow stress and G is Young's modulus. This quotient except between 200° and 270° K., is quite independent of the temperature. In this narrow range, however, there is a rapid slope, and Cottrell assumes that here only is this cutting mechanism, which he calls the effect of the 'forest', the one that determines the strength. He also determines from the behaviour in this range the energy of a jog; for copper it is about 4 eV.

It was particularly emphasized by Seeger (Stuttgart) that the jog energy in aluminium is much lower, perhaps 0·5 volt. This is because in face-centred cubic lattices the dislocations split into two half dislocations separated by a stacking fault. At a jog the two halves must be brought together again, and the energy required to do this is the greatest part of the energy of a jog. Now it is characteristic of monovalent metals that the energy of a stacking fault, as of a twin boundary, is very low; there is no contribution from interaction between nearest neighbours, and little from the electrons at the surface of the Fermi distribution due to the fault in the reflecting planes. Therefore the separation between the halves of the dislocation is large, and the work required to bring them together is large too. For zinc and aluminium it is much less, thus providing rather convincing evidence that the behaviour of electrons near the boundary of a Brillouin zone does provide a sort of long-range force between atoms that are not nearest neighbours.

According to Seeger, many of the differences between aluminium and copper are to be associated with this large difference in the energy of a jog Mechanical recovery and polygonization are believed to be dependent on the process known as 'climb'. when a dislocation gives off or absorbs vacancies But it can only do this at jogs, and so, if the log energy is low, climb and recovery without recrystallization can take place at low temperatures, as is the case for aluminium.

Dr. P. L. Pratt (Birmingham) and Dr. J. C. Fisher (General Electric Company, U.S.A.) emphasized that the dislocation forest is responsible for one kind of 'river line' marking observed on cleaved crystal faces. New river lines begin at places where the advancing crack crosses a region of localized plastic deformation or a low-angle boundary. A crack must develop a step whenever it cuts through a screw dislocation, and elementary river lines thus produced run together to form large steps. The cleavage stress is increased due to the extra surface exposed on these steps. Dr. Fisher mentioned an interesting consequence of this effect. The surface area associated with the river lines increases as r^3, where r is the radius of a radially expanding crack, and not as r^2. This upsets the Griffith criterion for a critical crack size. Previous treatments have deduced a critical size by balancing an r^3 elastic energy term against an r^2 surface energy term; but in circumstances where the above r^3 surface term predominates over the r^3 one, there will not be a critical crack size, and cracks of all sizes will grow at the same critical stress.

N. F. Mott

INTERNATIONAL UNION OF CRYSTALLOGRAPHY

THIRD CONGRESS

THE Third Congress of the International Union of Crystallography was held in Paris, at the Sorbonne, during July 21–30 and was attended by more than seven hundred members, representing some twenty different countries, including, it is gratifying to report, the U.S.S.R. This large membership raised several problems, particularly concerning the number of papers offered; these numbered about six hundred and were divided into groups of about ten, which were presented in seven parallel sessions. Since this system would normally give opportunity to members to attend only those sessions in which they were particularly interested, several survey papers were offered in addition. In this way, members were able to keep in touch with progress outside their own particular specialities. Aid in the choice of sessions was given by an 84-page booklet containing résumés of all the papers to be read.

It is naturally impossible, in this account, to deal with the whole of the Congress. Even had it been physically possible for a single person to be present at all the sessions, he could not have been expected to cope adequately with all the mathematics, physics, chemistry, mineralogy, metallurgy, biology and crystallography that would have been presented to him. The study of crystals is affecting intimately developments in many subjects; but in this article the writer will attempt only to direct attention to what seem to him to be the main lines of advance in the study of the solid state. A large number of papers were concerned with the details of crystal structures; these obviously will have to be ignored.

Crystal-structure Determination

The theory of methods of crystal-structure determination is at an interesting stage. At one time it was thought that, since the relative phases of the scattered beams could not be determined experimentally, it was impossible to devise a direct method of producing an image of a crystal structure. About six years ago, it was shown by D. Harker and J. S. Kasper, of General Electric, U.S.A., that the absence of negative electron density imposes certain conditions which, in some problems, enables the phases to be determined directly. This approach has led to many new ideas, and there is some possibility, according to J. Karle and H. Hauptmann, of the Naval Research Department, Washington, D.C., that a direct solution of *all* centrosymmetrical problems is possible. This view has been challenged by V. Vand and R. Pepinsky, of the Pennsylvania State University, and by M. M. Woolfson and W. Cochran, of Cambridge. It will be interesting to look back in a few years time to see how the subject has developed.

Meanwhile, although direct methods have produced several new structures, the main advances have been made rather by standard methods—Patterson synthesis, isomorphous replacement and 'heavy' atoms. Mrs. D. Hodgkin, of Oxford, described a partial solution of the structure of vitamin B_{12}; the molecule contains about a hundred atoms, almost three times as many as the most complicated molecule that has yet been dealt with successfully. Similar methods combined with the Fourier-transform concept have also enabled Sir Lawrence Bragg and M. F. Perutz, of Cambridge, to report some success with hæmoglobin, the molecule of which contains about ten thousand atoms. Unfortunately, the Fourier projection obtained, having a resolution of only 4 A., is not particularly clear, and some intense study will be required before any reliable deductions can be made from it.

This work illustrates the difficulty of studying such compounds by X-ray diffraction. There is still much rather subjective argument, and more evidence of the Bragg–Perutz type is needed to decide between the individual opinions concerning the nature of the protein structure.

Fine Detail of Structures

As experimental methods have improved, it has been found possible to distinguish more detail in the images of crystal structures. J. M. Robertson, of Glasgow, first showed that hydrogen atoms in organic crystals could be detected, and the difference synthesis of W. Cochran put this work on a sounder footing. Anisotropy of heat motion can also be measured, and further progress should enable electron distribution in bonds to be detected.

Methods other than X-ray diffraction can be used for detecting hydrogen atoms. Electron diffraction has provided some promising results, particularly in the hands of Z. G. Pinsker, of the U.S.S.R.

Low-temperature Studies

Room temperature is rather an arbitrary level at which to take X-ray photographs, and several different laboratories are working intensively on apparatus for cooling crystals to low temperatures. There are several reasons for this work: first, one can investigate compounds which are liquid at room temperature; secondly, there are many phase transitions below room temperature; thirdly, greater accuracy of co-ordinates can be obtained when heat motion is reduced; and finally, more detail for determining crystal structures can be obtained (although this may be regarded as a mixed blessing !). I. Fankuchen, of Brooklyn, gave a summary of methods that have been devised for taking photographs of crystals at liquid-nitrogen temperature. So far, most work has been concerned with the first two headings, but there is promise that the other two will also be developed.

Methods of Computation

Much of the work so far dealt with requires extensive calculations. Punched-card machines have been greatly used; but the greatest development since the last Congress has been in the use of electronic digital computors. In Britain, the most important machines are at Manchester and Cambridge, and work on these machines was reported by D. W. J. Cruickshank, of Leeds, and A. S. Douglas, of Cambridge. The former was chiefly concerned with the determination of fine structural detail, and the latter with direct methods of structure determination.

Diffractometers

As more complicated crystals are tackled, the mere process of amassing the diffraction data becomes formidable, particularly now that three-dimensional methods are so much used. Photographic methods can barely cope with the problem, and Geiger counters, coupled to recording apparatus, are becoming increasingly popular. Much ingenuity has been applied to this work, and it is to be hoped that soon some standard form of apparatus will be produced; at present there seems to be a gap between the people devising such apparatus and those who are working out complicated structures.

Neutron Diffraction

Despite the smallness of the number of atomic piles, the results of neutron diffraction are increasing rapidly. Having the experience of X-ray diffraction as a background, the workers in this field have made great progress, both in supplementing X-ray work in, for example, the investigation of superlattices and the detection of hydrogen atoms, and in discovering new phenomena such as antiferromagnetic structures, which cannot be found by X-rays. Most work has been done on powders, but a promising start has been made on single crystals; such crystals have still to be rather large, but it seems likely that rapid progress in the use of much smaller crystals will be made in the future. An instructive account of recent work was given by H. A. Levy, of Oak Ridge.

Crystal Growth

Emphasis on the crystalline state has stimulated work on the way in which crystals grow. F. C. Frank, of Bristol, presented an entertaining film showing the development of spiral growths in crystals. Many such examples are known, and in some quarters the process is believed to be a general one; there are, however, still some people who believe that it occurs for a few crystals only.

Crystal Imperfections

The existence of growth spirals implies that crystals containing them are imperfect, and indeed it has been known for a long time that perfect crystals would not diffract X-rays in the ways observed. The study of imperfections by means of X-ray diffraction is, however, difficult; it depends upon secondary effects not easy to interpret. B. E. Warren, of Massachusetts Institute of Technology, gave a general account of the investigation of one type of imperfection—order–disorder changes in alloys. These changes may be regarded as producing an imperfection based upon a perfect lattice and so should be easier to consider than imperfections of the lattice itself; much theoretical and experimental work has been done, but Warren maintained that the physical interpretation of the results is still obscure.

The conference gave a general picture of the consolidation of existing methods and rapid development of new ones. There seems to be a thriving future for the subject of crystallography, applied to many different branches of science. Much ingenious apparatus was shown in the accompanying exhibition.

In some ways, however, regret must be felt for the departure of the days when an individual worker could make an X-ray tube, construct a simple diffractometer, buy a set of Fourier strips, and produce contributions of real value to the subject. Nowadays, he appears to need an electronic computor, or at least a punched-card machine, some complicated diffractometers and a Geiger-counter outfit. The only steps in the opposite direction seem to be those which make use of optical analogies, introduced by G. von Eller in Paris and by the writer in Manchester. Crystallography will take its own course; but it will be a pity if it follows nuclear physics as a subject which can be studied only at centres large enough for complicated and expensive apparatus to be available.

A Congress of these dimensions could not have been easy to organize. It would have been better if there had been fewer papers; but granted the necessity for accepting all the papers offered, the organizers are to be congratulated on a most successful outcome of their efforts.

H. Lipson

OBITUARIES

Sir Lewis Fermor, O.B.E., F.R.S.

The death of Sir Lewis Leigh Fermor on May 24 removes one of the most distinguished geologists who have worked in India during the present century, and his passing at a time when there was still much for him to do is a severe loss to Indian geology.

Fermor was born in London on September 18, 1880. He was educated at Wilson's Grammar School, Camberwell, and was awarded a National Scholarship to the Royal College of Science in 1898. Hoping to secure a post at the Royal Mint, he took his A.R.S.M. in metallurgy. However, at the invitation of Prof. J. W. Judd, he became a student assistant in geology while working for his B.Sc., and it was Judd who persuaded him to apply for one of three vacancies in the Geological Survey of India before he had completed his B.Sc. course. He was duly appointed in 1902, along with G. E. Pilgrim and J. M. Maclaren and thus went to India primarily as a trained metallurgist, a fact that undoubtedly influenced the course of his geological work in India.

Soon after his appointment to the Survey, Fermor was deputed by Sir Thomas Holland to report on the manganese ore deposits of the country. Holland never anticipated that the investigation would be so detailed or so prolonged. But the resulting memoir was not published until 1909, and it extended to 1,294 pages. It was by this monumental work that Fermor became best known outside India. It included not only a detailed account of all the deposits, with a discussion on their mode of origin, but also important observations on the methods of mining, in which the pitch of the folded rocks was shown to be an important controlling factor. The field-work had also brought to light six new manganese minerals: hollandite, blanfordite, winchite, vredenbergite, sitaparite and juddite, while a seventh mineral, fermorite, was afterwards named after him.

On the completion of this work, Fermor was placed in charge of a party deputed to carry out a systematic survey of the Archæan rocks of the Central Provinces, and he himself surveyed a tract of country between Nagpur and Chhindwara, mapping the rocks in a more detailed manner than had ever before been attempted. The work was interrupted by the First World War, when his services were first lent to the Railway Board in connexion with the exploration of the Bokaro–Ramgarh coalfields, and later placed at the disposal of the Indian Munitions Board. In recognition of this work he was made an O.B.E. in 1919. After the War, work in the Central Provinces was resumed, and Fermor's own portion was completed in 1926. Unfortunately, administrative and other duties prevented the publication of this fine piece of work, though a summary of it was given in his later memoir on the correlation of the Archæan rocks of India.

Work of economic importance that Fermor accomplished during the same period included examination of the Singhbhum and Sikkim copper deposits, the iron ores of Ratnagiri and Goa, the Korea coalfield, the chromite deposits of Baluchistan and Singhbhum, and mica in Ajmer and Orissa.

In 1913 he had published a paper on "Garnet as a Geological Barometer". This was the starting point of a theme that was to recur more than once in his writings; for it led him to the conception of an infra-plutonic zone in the earth's crust composed of eclogite, which he considered to be responsible for the explosive nature of deep-focus earthquakes by the exothermic change of garnet to less dense minerals, for isostatic adjustments in the earth's crust, and for the high fluidity of the lavas of fissure eruptions. He also believed that the chondrules of stony meteorites had once been garnets. His views on these matters were elaborated in a series of lectures that he delivered to the Indian Association for the Cultivation of Science as Ripon professor for 1937, entitled "The Role of Garnet in Nature".

Before he retired from India, Fermor began the writing of a memoir that was to be an attempt at correlating the ancient schistose formations of India. After giving a general discussion on the factors to be considered in effecting a correlation, he had planned to give a summarized account of the geology of the eight Archæan provinces into which he divided India and Burma. Of this plan only the general discussion and about a quarter of the account had been published by 1940, and other commitments prevented the completion of further sections before his death. Thus a work that would have been of the greatest value to geologists in India has been left largely uncompleted.

In the Geological Survey of India, Fermor was promoted to the grade of superintending geologist at the early age of thirty. Though he first officiated as director in 1922, it was not until 1932 that he was substantively appointed to the post. It was unfortunate for him that his period of office coincided with a period of financial stringency in India. This compelled him to reduce the staff of his Department, and prevented him from planning the work of the Survey as he would have liked. In other directions, however, he was able to render service to India, in particular by the part he played in helping to bring into existence a national scientific academy for the whole of India at a time when conflicting interests were tending to divide scientific India. This was effected by the formation of the National Institute of Sciences of India, of which he became the first president in 1935. During the same year he was president of the Royal Asiatic Society of Bengal, while earlier he had been president of the Mining and Geological Institute of India in 1922, and general president of the Indian Science Congress in 1933. To each of these institutions he delivered original addresses that indicated the wide scope of his outlook. He was elected a Fellow of the Royal Society in 1934 and the honour of knighthood was conferred on him on the eve of his retirement after thirty-three years service.

Though he retired from official service in India in 1935, he continued to play an active part in scientific matters. Perhaps the most important of these was his visit to Malaya in 1938 to report on the mining industry of that country. This report must have proved of the greatest value when the time came to reconstruct the country after the Second World War.

On retiring to Bristol, Fermor took an active part in local scientific life, and became president of the Bristol Naturalists Society in 1945 and 1946. Finally, he was elected president of the Institution of Mining and Metallurgy for the year 1951–52, the subject of his presidential address being "The Mineral Deposits of Gondwanaland".

From the time that he first went to school until he left for India, Fermor's education cost his father little, for both at school and at college, by hard work and ability, he won scholarships that paid for his school and college fees. No doubt it was due to this that he was able throughout his life to apply himself with great concentration to the task in hand, while it may also have been responsible for the relatively spartan life that he led. In later years he mellowed, and the patience and tact that he displayed at the time of the formation of the National Institute of Sciences of India revealed to many a new aspect of his character, and won him many friends.

W. D. West

Dr. Saul Dushman

By the death of Saul Dushman on July 8, the General Electric Company of Schenectady has lost one of a small group of scientists who became world-famous and who established the scientific traditions of the Company's research laboratories—the group which included W. D. Coolidge, Irving Langmuir and W. R. Whitney.

Dushman was born on July 12, 1883, in Rostoff, Russia, and his family migrated to Canada in 1892. They settled in Toronto, and when Saul Dushman left the high school there in 1900 he had the best scholastic record ever achieved in the province of Ontario. This won him the Prince of Wales Scholarship at the University of Toronto, where he obtained his A.B. degree in 1904 and Ph.D. in 1911. Soon afterwards he joined the Research Laboratory of the General Electric Co. and remained on its staff until his retirement thirty-seven years later. He was assistant director from 1928 until 1948.

His early work was on physico-chemical problems; but at the suggestion of Dr. Langmuir he changed over to experimental and theoretical work on thermionic emission, to which branch of physics he soon made important contributions. In 1923 he applied the theory of the vapour-pressure constant for monatomic gases to the derivation of an expression for the constant A_0 of Richardson's equation, which differs only by a factor of ½ from the expression accepted to-day (electrons were not spinning in 1923!). On the experimental side, with various colleagues he determined the thermionic constants for a number of pure metals and also for metals covered with adsorbed layers.

This work led Dushman to take an interest in vacuum physics, an interest which persisted to the end of his life. He wrote a short book on the subject in 1922, upon which many of us were brought up, and in 1949 there appeared his monumental volume of 882 pages on the same subject. Throughout the book Dr. Dushman's wide personal experience in the field is evident, and his early interest in physical chemistry coloured his choice and treatment of various topics—as indeed it did in his work on thermionic emission. The book will long be a memorial to his encyclopædic knowledge of his subject, his enthusiasm and his desire to serve others.

His colleagues in the laboratory remember him also for his deep interest in human beings, his friendliness and, again, his desire to serve. Physicists all over the world will join with them in paying tribute to his memory.

F. A. Vick

Dr. K. T. Compton

Karl Taylor Compton was born on September 14, 1887, in Wooster, Ohio. He received his bachelor's and master's degrees from the College of Wooster, where his father, a Presbyterian clergyman, was dean and professor of theology. Compton spent the first part of his academic life doing research and teaching physics. He was awarded a doctorate at Princeton in 1912 and, after teaching for two years at Reed College, Oregon, returned to Princeton in 1915, where he remained until 1930, becoming chairman of the Department of Physics in 1929. His numerous papers covered a variety of physical topics, including ionization of gases, soft X-rays, spectroscopy in the extreme ultra-violet, fluorescence and dissociation of gases, electric arcs and other types of gas discharge and photoelectricity. His contributions in spectroscopy and thermionic emission were recognized by the award of the Rumford Medal of the American Academy of Arts and Sciences. In 1927 he became chairman of the Division of Physics of the National Academy of Sciences and was elected president of the American Physical Society.

He was a great teacher with a marked ability to inspire young men. To this skill was added a natural humanity and directness which brought forth the best in all who came within his influence. He brought these great personal qualities to the Massachusetts Institute of Technology, which he served as president during 1930–48 and then as chairman of the Corporation. Building on the sound traditions which he found in the schools of engineering and architecture, he added a school of science, greatly developed the graduate school and brought a humane and liberal spirit to its teaching of science, engineering and management.

Compton gave his time and energy freely in government service in capacities too numerous to mention in any detail. He served in the Signal Corps during the First World War and was chairman of the Science Advisory Board (1933–35) appointed by the President of the United States to advise on the better use of science in commerce and government. As a member of the National Defense Research Committee during the Second World War, he was responsible for American radar development. In the early stages of the War he was a member of the Baruch Rubber Survey Committee and at its end was in the Philippines directing the field service of the Office of Scientific Research and Development. His advice was sought after the War on the evaluation of atom bomb tests and other aspects of atomic energy, and he served as chairman of the Research and Development Board of the National Defense Establishment. He was awarded the Medal for Merit in 1946 for his distinguished war-time services.

He served numerous institutions and companies as director or trustee, including the Ford, Rockefeller, Nutrition and Sloan Foundations and the Research Corporation.

Compton's qualities and experience were recognized in Great Britain. He was Pilgrim Trust Lecturer of the Royal Society in 1943, became an honorary Fellow of the Imperial College of Science and Technology in 1949 and received an honorary degree at Cambridge in 1952. He became an honorary C.B.E. in 1948. A few weeks before his recent death he was advising the Parliamentary and Scientific Committee on Technological Education.

Compton received the enthusiastic support of his colleagues in his great achievements at the Massachusetts Institute of Technology. He was in a large measure responsible for the atmosphere of comradeship, vitality and quiet confidence which permeates its staff and student body. His selflessness, his nobility and his true appreciation for others were an inspiration, and his wisdom and stalwart commonsense were sure guides in the growth and changes which he fostered. He understood and did his best to achieve the conditions in which scientific work and learning could flourish. At the same time, he was deeply conscious of the responsibility of scientists and technologists to the community.

The loss of this sturdy, generous and inspiring personality will be felt keenly not only by his friends and his Institute, but also by a world grappling with the many problems posed by modern technology.

W. R. Hawthorne

NEWS and VIEWS

Broadcasting Arrangements for the British Association Meeting at Oxford

The presidential address by Dr. E. D. Adrian to the British Association in Oxford on September 7 will be broadcast in the Home Service and on television. Conferment of honorary degrees on this occasion will also be televised, as well as two important talks by eminent speakers on September 2 and 3 and the service from Christchurch Cathedral on the 5th. A summary will be presented in the Home Service on the 8th. Viewers will first see on September 1 the Convocation in the Sheldonian Theatre at which honorary degrees of doctor of science will be conferred by the vice-chancellor, Sir Maurice Bowra, on Sir Ben Lockspeiser, secretary to the Committee of the Privy Council for Scientific and Industrial Research, Sir John Lennard-Jones, principal of the University College of North Staffordshire, and Sir Harold Spencer Jones, the Astronomer Royal. The proceedings will be explained by Richard Dimbleby. The producer is David Martin. Following this ceremony will come the speeches of welcome from the Vice-Chancellor and the Mayor, and then the presidential address by Dr. E. D. Adrian. The first part only of the address will be televised; but listeners to the Home Service will hear the whole of it.

On September 2, in a talk on "Physics and the Future", viewers will see Prof. P. M. S. Blackett discussing the growing impact of physics on our present-day life, and the following day Prof. C. D. Darlington talking about "Genetics and Man" and dealing with some recent advances and future work in this field. Both talks will have illustrations and demonstrations; they will be introduced by Peter Parker, who will also report for television on each day's activities during the meeting. The producer is George Noorhof. The service in connexion with the meeting on Sunday morning, September 5, at Christchurch Cathedral, will also be televised. There will be three processions: that of the Vice-Chancellor, proctors and beadles, of the Mayor and Corporation, and of the officers of the British Association. The preacher will be Prof. Leonard Hodgson, regius professor of divinity; the First Lesson will be read by Dr. Adrian, and the Second Lesson by the Dean, the Very Rev. John Lowe, who will conduct the service. At the end of the meeting, in a Home Service programme on September 8 called "Scientists in Session", some of those present will give their views and impressions by recordings made in Oxford the previous week.

New Chief Scientist of Ministry of Fuel and Power: Mr. K. T. Spencer, C.B.E.

Mr. K. T. Spencer has been appointed chief scientist of the Ministry of Fuel and Power in succession to Sir Harold Roxbee Cox. Born in 1898, Mr. Spencer served as an officer in the Royal Engineers in the First World War and afterwards graduated at the University of London. He entered the Scientific Civil Service in 1923 and spent twelve years at the Royal Aircraft Establishment, Farnborough, in the branch dealing with problems of aircraft design and safety. In 1935 he was transferred to the Air Ministry in London, and up to the outbreak of war took part in the organization of the research, development, production, and safety certification of civil aircraft of all kinds. He went to the Ministry of Aircraft Production on its creation in 1940, and throughout the War was concerned with the expansion of research and development activities here and in Commonwealth countries. Mr. Spencer was a member of the first Brabazon Committee, whose recommendations shaped the first post-war generation of civil air-liners. Towards the end of the War he was seconded to the Air Registration Board to help them build up the technical organization needed to discharge civil aircraft certification duties delegated to them by the Secretary of State for Air. In 1946 he served for six months as an international Civil servant with the Provisional International Civil Aviation Organization in Montreal, and set up their Airworthiness Section. Later he went to New Zealand with a United Kingdom Civil Aviation Mission, led by Sir Frederick Tymms, invited by the New Zealand Government to advise them on aviation matters. He joined the Ministry of Fuel and Power in 1950 as deputy chief, under Sir Harold Cox, of the Scientific Division that had been set up in 1948.

Bacteriology at Belfast: Prof. G. W. A. Dick

Dr. George W. A. Dick, of the scientific staff of the National Institute for Medical Research, Mill Hill, has been appointed to the chair of bacteriology in The Queen's University of Belfast. Prof. Dick, who is thirty-nine, graduated from the University of Edinburgh in 1938 and gained his M.D. in 1949, when he was awarded a gold medal for his thesis. He served with the Royal Army Medical Corps during the Second World War, mainly in Africa with a mobile bacteriology laboratory, and was promoted to lieutenant-colonel in 1945. Having acquired an interest in viruses and rickettsiæ, Prof. Dick was appointed in 1946 to the staff of the Virus Research Institute, Entebbe, Uganda, and there he made valuable contributions to knowledge of yellow fever and some of the recently isolated African viruses. During 1948–50 he held a Rockefeller Foundation fellowship, working at the Rockefeller Institute, New York, and later in Baltimore, largely on poliomyelitis. He then returned to Entebbe and acted for a time as deputy director before going to England in 1951 to the National Institute for Medical Research, where for almost three years he has been working in the Department of Bacteriology and Virus Research, chiefly on hepatitis. Prof. Dick has published forty papers, almost all on viruses. He has lately been appointed joint secretary of the Medical Research Council's Poliomyelitis Committee.

Olaus Wormius (1588–1654)

Olaus Wormius (Ole Worm), who died at Copenhagen three centuries ago, on August 31, 1654, is an interesting example of the seventeenth-century polyhistor, whose fame and authority were as great in his own country as they were abroad. Of Dutch descent, he was born on May 13, 1588, at Aarhus in Jutland, where his father was burgomaster. He was educated at the Gymnasium in Luneburg, studied theology at Giessen and Marburg, medicine at Strasbourg and at Basle under Caspar Bauhin, and at Padua under Fabricius and Giulio Casserio; after visiting Montpellier and Paris, he took his doctorate at Basle in 1611. Having practised in London for a time, he was appointed professor of Greek and of philosophy at the University of Copenhagen in 1613, and in 1624 succeeded his brother-in-law, Caspar Bartholin Primus, as professor of anatomy and of medicine. Bauhin had inaugurated the Paduan tradition of anatomy at Basle, and Bartholin and Worm took it to Denmark. An able and enthusiastic teacher, Worm was also five times rector of the University of Copenhagen, and physician to King Christian IV. He made no original discoveries in science, though his name was attached by Bartholin to the Wormian bones in the sutures of the skull, which were familiar to the ancients and were also described by Eustachius. Known as the 'father of Danish archæology', Worm compiled six volumes of runic inscriptions, "Monumenta Danica" (1643), and founded a collection of natural history, ethnographic and archæological objects, which after his death passed into the possession of the Cabinet of Curiosities at Copenhagen. His son Willum, professor of medicine in the University, edited the catalogue of the museum in 1655, and he was succeeded in the chair by his son Ole.

Energy Transfer in Hot Gases

The sixth in the series of twelve conferences which were held at the United States National Bureau of Standards during 1951 to mark the fiftieth anniversary of its establishment consisted of a symposium on energy transfer in hot gases and dealt with the problems of radiation from flames and hot gases and the basic and physical mechanisms governing energy transfer in these media. The proceedings of the symposium have now been issued in book form (Circular 523, March 10, 1954; pp. 126. Washington, D.C.: Govt. Printing Office; 1.50 dollars). The contents consist of sixteen scientific papers covering many different aspects. A. G. Gaydon deals with processes of electronic excitation in relation to flame spectra; G. A. Hornbeck and R. C. Herman indicate the importance of using low-temperature, high-intensity sources for the study of polyatomic flame spectra; S. S. Penner, M. Gilbert and D. Weber summarize recent work on high-resolution spectra of hydrocarbon flames in the infra-red between 1 and 2·6 μ using lead sulphide photoconductive cells; and S. S. Penner gives an outline of basic theoretical relations used for calculating the infra-red emissivity of diatomic gases. The present position of the theory of flames, by B. Lewis, is a more general survey of the subject in which fields that require further basic study are indicated. A paper on some reactions of atomic hydrogen in flames, by J. R. Arthur and D. T. A. Townend, is a summary of methods of detecting the presence of atoms in flames and includes a description of some of the experiments conducted at the British Coal Utilization Research Association, Leatherhead. The concluding article in the volume is a brief account by H. K. Sen of an astrophysicist's concept of temperature.

Strength Properties of Plywood

In Bulletin No. 29 of the Forest Products Research Laboratory, Princes Risborough, the strength properties of plywood are considered in "Comparison of 3-Plywoods of a Standard Thickness, Part 1", by W. T. Curry (pp. iv+10; London: H.M.S.O., 1953; 1*s*. 3*d*. net). The methods described in the bulletin are used to determine the bending, tension, compression, shear and impact strength of plywood. The results obtained from tests on twenty-five different species of 3/16-in. three-plywood are included. A comparison of the strength properties of the various species is shown in block diagram form with the names of the twenty-five plywoods used. The results indicate that Canadian birch plywood possesses the greatest shear strength. Those experimented with were species of the genera *Terminalia*, *Catostemma*, *Berlinia*, *Betula*, *Bursera*, *Octomeles*, *Daniellia*, *Cistanthera*, *Aucoumea*, *Ocotea*, *Khaya*, *Afrormosia*, *Protium*, *Sterculia*, *Mimusops*, *Mora*, *Tarrietia*, *Araucaria*, *Calophyllum*, *Pterygota*, *Gonystylus*, *Shorea*, *Parashorea*, *Sterculia* v. *rhinopetala* and *S. oblonga*. It is stated that Part 2 of the bulletin will cover investigations on the effect of the shape and thickness of the veneers used in the construction of plywood upon its strength and it will be issued separately when results are available. The object of the whole investigation is to obtain strength data which will allow the comparison of plywoods made from various species of timber and the derivation of working stresses.

Radioactive Tracers in Plant Nutrition

R. P. Martin and R. Scott Russell have reported on the effect of radiation from phosphorus-32 on the growth and phosphate utilization of barley seedlings maintained in water culture (*J. Exp. Bot.*, 5, 91; 1954). Concentrations of carrier phosphate ranging from less than 0·01 to 31 p.p.m. phosphorus were employed for varying periods. It was observed that between experiments there were wide variations in the nature and extent of the effects of radiation. An increase in the proportion of the absorbed phosphate translocated to the shoots, and the reduction of root weight, were the most consistent symptoms. While severe injury was characterized by a reduction in both growth and phosphate absorption, intermediate levels of phosphorus-32 on occasion caused increases in dry weight, in nutrient absorption, and in the development of lateral meristems. The reduced metabolic activity of root meristems is considered to be the primary effect in the syndrome of radiation injury. Although injury is due to the accumulation of phosphorus-32 in meristematic regions, no close correlation could be shown between its extent and the level of radiation received by the meristems. The inaccuracy of present methods for estimating the levels of radiation to which tissues are exposed has complicated the investigations of this subject. It appears, however, that the injurious level of radiation may vary from less than 10 to more than 40 rep. per day when the treatment period is 5–7 days. If active accumulation of phosphate occurs, the meristems of plant roots may receive this dosage when treated with more than 5 μc. of phosphorus-32 per litre for periods of six days. The authors discuss the extent to which the effects of radiation may complicate the interpretation of the results of plant physiological investigations.

Forestry in Nigeria: Annual Report for 1951–52

The political and administrative changes which are taking place in some of the Colonies of the British Commonwealth are having their inevitable repercussion on the Forest Departments. Nigeria is now divided into three largely self-governing regions, termed Northern, Eastern and Western, which are united under one Central House of Representatives and a Council of Ministers. Thus, as is indicated in the annual report of the Forest Department for 1951–52 (pp. 38. Lagos: Government Printer; London: Crown Agents for the Colonies; 1953; 9*d*. net), the Department becomes a regional matter and, accordingly, it, though nominally still a unit, has been split into three more or less independent sections under a Chief Conservator. At the centre, as the adviser of the central government, is an Inspector-General whose functions are to see that the Regions are carrying out a central policy, to act as a co-ordinator between the Regions, to advise on distribution of staff, for whose discipline, promotion and so forth he is largely responsible and to be the general representative of Nigeria in forestry matters. The present report, written by the Inspector-General, states: "All powers under existing legislation, save for such central concerns as control of exports or the appointment of staff, have been transferred to the Regions". This removal of function from the centre applies to the policy, too, and where the ultimate decision regarding dereservation of any parts of the forest estates was specifically vested in the Governor, it now lies regionally with the Lieutenant-Governor concerned. On the subject of the size of the forest estate, it is pointed out that the "overall percentage falls far short of what the optimum of a Forest Estate in this or any other country should be". The report deals with the forest administration as a whole—the main features of the regional reports. The Forest Research Branch, as also the Forest School, remains under the Inspector-General; the work of the former is becoming increasingly important.

Bird Preservation

The report for 1953 of the International Committee for Bird Preservation directs attention to the fact that the Committee has now been in existence for thirty-one years and gives many examples of the ready co-operation existing between the various national sections; the success of the international conference on oil pollution of the sea, held in London in October last year, is a striking example. In addition to the urgent question of oil pollution the British section has also been engaged in work in connexion with new legislation for the protection of birds. Early in the year a number of complaints were forwarded to the British section concerning a measure it was proposed to bring into force in Cyprus under which the use of bird-lime for catching birds would be permitted. The British section pointed out to the Secretary of State for the Colonies that the practice had been condemned by almost every country in Europe, and its prohibition was contained in the International Convention for the Protection of Birds, which was signed *ad referendum* in Paris in May 1950 by representatives of twelve different countries. The matter was settled satisfactorily.

During the year the Scottish Ornithologists' Club undertook to make an investigation into the effect of herring gulls on other species, and appointed Dr. J. A. Gibson to take charge of this work. This is part of a scheme which was initiated at a meeting in Sweden in 1950 when it was decided to make a yearly survey of the numbers and details of herring gull colonies in the countries bordering the North Sea, with observations of the effects of these birds on other species, and records of the measures taken to control their numbers and the results obtained. Detailed records are being kept in Denmark, Germany and Holland; but the problem is far more difficult in the British Isles. The report also contains further details of the inquiry into status of the wildfowl of Europe.

Museum Techniques

SEVERAL interesting papers are contained in the April issue of *Conservation* (1, No. 3; 1954), the journal of the International Institute for the Conservation of Museum Objects. Mr. W. G. Constable reviews the whole basis of conservation, especially in relation to problems of responsibility and general administration, and deals with the tasks of a curator as distinct from a conservator. An article on the Coronation Chair in Westminster Abbey proves that there have been two distinct decorative treatments, the first one consisting of paint and being in all probability Walter's original scheme. This was replaced at some undocumented date by a second one, richer and more elaborate, transforming the chair into a gilded throne. The radiographs also show the crude repairs of earlier times carried out with nails or screws. Prof. F. C. Thompson and Dr. A. K. Chatterjee write concerning the age-embrittlement of silver coins, and the issue closes with some useful reviews. Curators who also—and indeed should—deal with conservation will find much of interest and help in this new and worth-while publication.

University of London Appointments Board: Report for 1953

THE forty-third annual report of the Appointments Board of the University of London, which covers the year ended December 31, 1953, notes specially, first a decrease in the number of registrations of men in the age-group 21–25 years (probably due to the increasing number who elect for National Service after taking their degree), and second, the doubling of the number of appointments secured by women graduates. Fewer teaching vacancies were notified to the Board; but there is no evidence to support the thesis that an increase in the number of graduates will alleviate the shortage of good teachers in scientific subjects. Although a number of good biologists on the Register are seeking a career in research or scientific work generally with no great prospects of suitable posts, they are unwilling to consider school teaching, although the vacancies are not unattractive. In previous years the greatest demand was for chemists; but during 1953 the main pressure was for engineers, chiefly those with mechanical and electrical training. There is a shortage of civil engineers for municipal work, and the Civil Service still attracts a substantial proportion of the best scientific workers and engineers. Of 617 men and women placed in full-time posts during the year, only four took science teaching posts in secondary schools, twenty taking university appointments, fourteen technical college appointments and twelve full-time tutorships. The Register at December 31, 1953, included 957 names compared with 1,042 on December 31, 1952; of these, 36 held an engineering degree, 50 general degrees in science, and 128 other degrees in science (biology, 39; chemistry, 31; mathematics, 33; and physics, 19).

United States National Museum: Annual Report for 1952–53

THE annual report of the United States National Museum, under the direction of the Smithsonian Institution (pp. vii+98. Washington, D.C.: Government Printing Office, 1953), always provides stimulating and impressive reading, and that for 1953 is no exception. Starting with the recognized two-fold function of a museum to preserve objects for posterity and to enlarge the scope of human knowledge by a critical study of the collections, it continues with the outline of a scheme to modernize the exhibits. The Museum is really three museums in one: a natural history museum dealing with plants, animals and minerals; a museum of anthropology dealing with ancient and modern man and his works; and a museum of national history and technology. The present policy is to interpret this three-fold aspect in a broad, integrated panorama of life. The report then details some of the exhibition work which has already been accomplished towards this lofty goal. A most impressive part of the report is an account of the investigations and researches carried out by individual members of the staff—a clear indication that they have not allowed the factual minutiæ of day-by-day work to dull their imaginations. A total of more than a hundred and fifty papers were published during the year.

Lundy Field Society

THE seventh annual report of the Lundy Field Society describes the year's working as one of consolidation. Much of the work on the non-avian fauna and the flora of Lundy was made up of contributions towards long-term surveys which are not yet complete enough for report. One paper, however, by M. T. Delany, describes his observations on the habitats of the bristle-tail, *Petrobius maritimus*. Within the limits of Lundy, the distributional range of this insect is wide. Providing rocks are available, whether they be slate or granite, capable of offering the appropriate cover, populations of *Petrobius* will survive. The factors, and their differential effects, responsible for the maintenance of the population balance of *Petrobius* in various localities have still to be determined. The other paper describes the observations of A. L. Galliford on the freshwater localities of Lundy; he now reports on the minute waterfleas and wheel animalcules. The report also includes a short summary on the domesticated and semi-domesticated stock which adorn the island.

British Weed Control Conference at Harrogate

THE British Weed Control Conference will be held this year during November 2–4, at the Majestic Hotel, Harrogate, under the presidency of Sir James A. Scott Watson, chief scientific and agricultural adviser to the Ministry of Agriculture and Fisheries. The Conference is being organized by the British Weed Control Council, which is composed of representatives from the Ministry of Agriculture and Fisheries, the Department of Agriculture for Scotland, the Ministry of Agriculture for Northern Ireland, the Agricultural Research Council, the Colonial Office, the Association of British Insecticide Manufacturers, the British Agricultural Contractors Association, the National Association of Corn and Agricultural Merchants and the National Farmers Union. The formal papers will cover the present position of herbicides in British agriculture; cultivation and weed control; chemical weed control in the United States with special reference to horticulture; rotation of weed killers; spraying machinery; economics of commercial applications; legal aspects of spray damage; weed persistence and dispersal; weed dispersal by machinery; the present position concerning the law; the Ministry approval scheme for herbicides; and woody weeds with particular reference to the British Colonies. In addition, reports will be presented by research workers from many sources on new herbicides, mixed herbicides and herbicides plus nutrient or crop-protection agents, total herbicides, mode of action of herbicides, experimental techniques, weed control in horticultural crops, grasses and legumes, and the winter spraying of cereals. Accommodation at the Majestic Hotel must be booked before October 4. A Conference registration fee of £2 10*s*. will be charged which will include a copy of the proceedings. All communications should be addressed to the Conference Treasurer, Mr. W. A. Williams, Association of British Insecticide Manufacturers, Cecil Chambers, 86 Strand, London, W.C.2.

Fourth World Forestry Congress, Dehra Dun

The Fourth World Forestry Congress will be held in Dehra Dun at the Indian Forestry Institute during December 11–22. The occasion will be of noteworthy interest in that this will be the first time that the Congress will have been held outside Europe, and although some aspects of the utilization of tropical timbers have been considered at previous Congresses, this will be the first one at which special emphasis will be laid on tropical forestry. The discussion on tropical sylviculture will also include the control of desert areas and problems arising from shifting cultivation in various parts of the tropics. In general, the theme of the Congress will be on the land economy and economic development of the country as a whole. Besides visits to forest areas in India, arrangements have also been made for the delegates to make tours in Pakistan. Further information regarding the Congress can be obtained from the Inspector-General of Forests, Ministry of Agriculture, New Delhi.

The Night Sky in September

Full moon occurs on Sept. 12d. 20h. 19m., U.T., and new moon on Sept. 27d. 00h. 50m. The following conjunctions with the moon take place: Sept. 1d. 15h., Venus 3° N.; Sept. 2d. 14h., Saturn 7° N.; Sept. 7d. 10h., Mars 3° S.; Sept. 21d. 16h., Jupiter 1° N.; Sept. 29d. 08h., Mercury 3° N.; Sept. 30d. 02h., Saturn 7° N.; Sept. 30d. 22h., Venus 1° S. In addition to these conjunctions with the moon, Jupiter is in conjunction with Pollux on Sept. 12d. 14h., Jupiter 6·7° S.; Venus is in conjunction with Saturn on Sept. 16d. 03h., Venus 6·1° S.; Mercury is in conjunction with Spica on Sept. 23d. 17h., Mercury 0·6° N. Mercury is too close to the sun throughout September to be seen. Venus is an evening star, setting at 19h. 50m., 19h. 10m. and 18h. 25m. at the beginning, middle and end of the month, respectively. The visible portion of the illuminated disk rapidly decreases from 0·513 to 0·341, but owing to the decrease in the planet's distance from the earth—from 67 to 46 millions of miles—the stellar magnitude increases from $-4\cdot0$ to $-4\cdot2$. Mars, an evening star, sets at 22h. 50m., 22h. 30m. and 22h. 15m. on September 1, 15 and 30, respectively: the planet's fairly large declination south—about 26°—renders it rather unfavourable for observation in the British Isles. Jupiter rises at 0h. 50m., 0h. 10m. and 23h. 25m. at the beginning, middle and end of the month, respectively; its easterly movement in the constellation Gemini is easily seen, and this movement will continue until the middle of November. Saturn sets at 20h. 40m., 19h. 45m. and 18h. 50m. on September 1, 15 and 30, respectively, but in the last case only about an hour after sunset. It is easily recognized in the constellation Virgo and is a little brighter than a first-magnitude star; its easterly movement takes it into the constellation Libra about the middle of the month. Occultations of stars brighter than magnitude 6 are as follows, observations being made at Greenwich: Sept. 20d. 02h. 59·9m., 36*B* Gemi. (*R*); Sept. 24d. 04h. 29·9m., π Leon. (*R*); *R* refers to reappearance. Autumnal equinox occurs on Sept. 23d. 14h.

Announcements

The first Drummond Fellowship in nutrition has been awarded to Dr. Iain MacIntyre at the Postgraduate Medical School of London. The Drummond Fellowships are endowed from the proceeds of a recent appeal in memory of the late Sir Jack Drummond.

In order to deal with the numerous inquiries that are received for advice on the prevention of corrosion of ferrous metals, the British Iron and Steel Research Association has formed a Corrosion Advice Bureau, which will be at 140 Battersea Park Road, London, S.W.11. Dr. J. C. Hudson has been appointed head of the Bureau, Mr. E. E. White as secretary, and Dr. W. H. J. Vernon as consultant. The services of the Bureau will normally be free to members of the Association, and also available to others on a fee-paying basis.

The jubilee of the application by Sir Ambrose Fleming for the British patent for his thermionic valve will be celebrated by the Institution of Electrical Engineers on November 16, exactly fifty years after the event. The proceedings will be opened by the Lord President of the Council, the Marquess of Salisbury, and three lectures will be delivered, by Sir Edward Appleton, Prof. G. W. O. Howe and Dr. J. Thomson, respectively, dealing with valves from the earliest developments to the present day. There will also be an exhibition of historical apparatus.

The Seventeenth International Congress of Industrial Chemistry will be held in Brussels during September 11–19, this being the fifth time that the Congress has met in Belgium. The Congress will include twenty-nine sections grouped under the following ten main headings: general problems of the chemical industry; fuels; nuclear science; metallurgy; industrial inorganic chemistry; cements, building materials, glassware, ceramics and enamels; industrial organic chemistry; foodstuffs and agricultural industries; Colonial problems; and organization (industrial, commercial and professional). Further information can be obtained either from the Secrétariat du Comité d'Organisation, XXVIIème Congrès International de Chimie Industrielle, 32 Rue Joseph II, Brussels, or from the Commission permanente d'Organisation des Congrès de Chimie Industrielle, 28 Rue Saint Dominique, Paris 7ᵉ.

W. Watson and Sons, Ltd. (313 High Holborn, London, W.C.1), makers of microscopes, optical and scientific instruments, are holding an exhibition on "The Microscope in Industry and Research", in Milton Hall, Deansgate, Manchester, during September 20–25 (10.30 a.m.–7.30 p.m.; except September 25, closing at 2 p.m.). Eighteen firms or other organizations are supplying exhibits illustrating the microscope in connexion with various processes.

DEVELOPMENT AND WELFARE IN THE BRITISH COLONIES

REPORT FOR 1953–54

THE schemes detailed in the latest return made under the Colonial Development and Welfare Acts, covering the period April 1, 1953–March 31, 1954[*], bring the total commitments for development and welfare schemes under the Acts to £110,879,335, of which £14,729,660 was for the year in question, and for research schemes to £12,401,606, of which £716,818 was for the year ended March 31, 1954. Of this last-named sum, £249,596 was for agriculture, £205,312 for medicine, £83,226 for social science, £96,923 for insecticides, £22,100 for tsetse and trypanosomiasis, £32,295 for products research, £7,137 for fisheries and £7,059 for economic research. There were no grants for research fellowships.

Of the actual research schemes, much the largest were £123,743 for the establishment of the West African Council for Medical Research, £110,000 for the continuation of research at the East African Veterinary Research Organization, a supplementary £66,984 for the maintenance of the West Indian Institute of Social and Economic Research and £50,000 for the control of malaria in the hyper-endemic area at Taveta-Pare, East Africa. A supplementary £31,330 was provided for the continuation of sugar technology research at the Imperial College of Tropical Agriculture, Trinidad, while the West Indies also received £23,371 for research into the 'unknown' disease of coconuts and Panama disease of bananas, and £14,300 for banana breeding research (both in Jamaica) and a supplementary £2,444 for research into the control of leaf-scald disease of sugar-cane in British Guiana. East Africa received supplementary grants of £18,750 for the preparation of the "Flora of Tropical East Africa" at the Royal Botanic Gardens, Kew, £16,000 for the establishment of a malarial unit and £8,500 for the establishment of a team in Tanganyika for insecticides research on the control of crop pests.

In West Africa £14,780 was provided for the establishment of a fungicide research unit, £12,250 for the maintenance of the West African Institute for Trypanosomiasis Research, £12,290 for the expansion of the Veterinary Research Laboratory, Vom, Nigeria, and £9,850 for a pilot scheme for tsetse reclamation. £16,022 was provided for an investigation into the control of filariasis in Fiji by insecticidal methods, and £6,975 for the establishment of the Fisheries Research Unit at the University of Hong Kong. In south-east Asia the Federation of Malaya received £14,915 for research on virus and other diseases transmissible from animals to men and £9,334 for the establishment of a Timber Research Station, and North Borneo £9,784 for an investigation of the diseases of the manila hemp plant. A general grant of £13,525 was for the establishment of a pool of Colonial soil surveyors.

Grants of particular scientific interest for development and welfare schemes include the following: £182,101 for the Desert Locust Control campaign in East Africa; £37,000 for the establishment of the agricultural and veterinary training centre at Lilongwe, Nyasaland; £22,300 for the development of medical and health services in Gambia; £474,600 for land planning and soil conservation in the Northern Territories of the Gold Coast; £162,030 for the control of leprosy in Nigeria, for which £181,335 is also provided for a scheme in the Development Plan towards which a supplementary £2,583,551 was granted. Out of that sum, supplementary schemes for agriculture received £273,417, for technical education £347,113, and for medical and health £386,679. £100,000 was provided for tsetse control in the northern region of Nigeria, £68,039 for the geological survey of Sierra Leone, while among other grants the University College of the West Indies and its associated teaching hospital received £120,000 for the main building programme; the Nigerian College of Arts, Science and Technology, Ibadan, £124,410 for the construction of student accommodation; the University College of the Gold Coast, £400,000 for the construction of a hall of residence; University College, Ibadan, £51,600 for the development of the permanent site; and Makerere College, £180,000 for the construction of a men's hall of residence, senior staff housing and science laboratory.

[*] Colonial Development and Welfare Acts. Return of Schemes made under the Colonial Development and Welfare Acts by the Secretary of State for the Colonies with the Concurrence of the Treasury, in the Period from 1 April, 1953, to 31 March, 1954. (Colonial No. 181.) Pp. 26. (London: H.M. Stationery Office, 1954.) 1s. 3d. net.

PROFESSIONAL, TECHNICAL AND SCIENTIFIC CIVIL SERVANTS

IN evidence submitted to the Royal Commission on the Civil Service, the Institution of Professional Civil Servants claims that the status and standing of professional, technical and scientific Civil servants in relation to the remainder of the Civil Service should more accurately reflect the relations existing between the administrator and the professional man outside the Civil Service and the importance of the professional man in the life of the country as a whole; they should also be such as to encourage young people to take up professional, scientific and technical careers. At present the heads of the various sections of the professional Civil Service are in an unsatisfactory position with respect to each other and especially to the administrative class; the highest professional officer is always a grade lower than his administrative colleague, and this relation, applying right down to the lowest technical grades, is a factor in diminishing the attractiveness of such careers.

After referring to Lord Cherwell's statement for the Government in 1943, and the representations made in the Barlow Report and by the Parliamentary and Scientific Committee, the Institution urges that the Commission has the opportunity to place science on an equality with administration and that this would constitute a major advance. It suggests that there is complete justification for the claim that the post of deputy chief scientific officer should rank with that of under-secretary in the administrative class; that of senior principal scientific officer should rank with that of assistant secretary, while the senior scientific officer grade should be abolished or combined with that of principal scientific officer to rank with that of principal in the administrative class. The scientific officer grade should rank with that of assistant principal, and a considerable increase in the number of posts in grades above that of principal scientific officer is necessary to make the career open to the scientist sufficiently attractive compared with that open to the administrator.

As regards the works group of professional classes, whose position was reviewed by the Gardiner Committee in 1951, the Institution submits that a wholesale change is necessary to put such professional officers on a basis that reasonably recognizes the degree of responsibility they carry compared with that of the administrative class. It is suggested that the main grade should be equated with the administrative principal, the senior grade with the assistant secretary and the superintending grade with the under-secretary in the administrative class. As regards the experimental officer class, the Institution submits that a broad comparison should be made between the assistant experimental officer and the executive officer, the experimental officer and the higher executive officer, the senior experimental officer and the senior executive officer and between the chief experimental officer and the chief executive officer, with salary scales favouring the experimental officer class in view of the higher standard of qualification, the inferior promotion prospects and the increased responsibilities. For the assistant (scientific) class, the Institution submits that the assistant (scientific) and the senior assistant (scientific) grades should be placed on salary scales sufficiently higher than those of clerical officer and higher clerical officer to be attractive in competition with the careers and salaries available to officers in those grades. It is also submitted that to provide a proper career for technical officers it is imperative to increase the scales of these classes to a basis of parity with the executive class. Other proposals relate to the admission to the appropriate professional scales of those who have obtained professional qualifications after entry to the Civil Service and for the simplification and reduction of the number of salary scales.

BRITISH WELDING RESEARCH ASSOCIATION

THE ninth annual general meeting of the British Welding Research Association was held on July 14 at the Association's Engineering Research Station at Abington, near Cambridge, under the chairmanship of the president, Sir William J. Larke. At the subsequent luncheon, a toast to the Association was proposed by Dr. O. Wansbrough Jones, chief scientist, Ministry of Supply, and acknowledged by Sir Charles S. Lillicrap, chairman of the Council. In his speech, Sir Charles made reference to the annual income, which had reached £113,000 (being an increase of £20,000 over that for the previous year), and also to the new terms of the grant from the Department of Scientific and Industrial Research which had again been agreed for the next two years at the level of £100 for each £100 of membership subscription. Nevertheless, it was pointed out that in order to qualify for this grant after the end of the period, it would be necessary for the annual subscription income to be raised by £10,000 to £50,000. He was sure that this would be possible, if the goodwill of members was secured. Mention was also made of the Association's intention to move the metallurgical researches from London to Abington in the near future. For this purpose a provision of £40,000 has been made for new laboratories, and a housing association has been formed.

During the day an exhibition was staged of metallurgical work in progress, and the engineering laboratories were open to view. The metallurgical work is to be the subject of a separate open day in the autumn, and the examples illustrated were confined to the micro-analysis of hydrogen in metals and weld deposits, and the development of a suitable cracking test for light alloy welds with various parent materials and filler alloys. Associated work has shown the important influence of silicon dilution of the filler alloy by the parent plate, as a cause of cracking in welds made in the heat-treatable aluminium alloy H.10.

In the fatigue laboratory tests were shown in progress on butt welds in heavy sections of steel plate and tube. Various welding methods are being investigated, together with the effect of deliberately introduced faults. An interesting effect of one such fault—lack of penetration—which introduces the equivalent of a sharp notch, is that although the joint fatigue strength is much impaired, the relative scatter of results is reduced to negligible proportions. In another test, conducted co-operatively with the Department of Metallurgy, University of Cambridge, large steel specimens which have been fatigue-tested to destruction have been sub-divided so as to avoid the main fracture faces, for further fatigue tests on a smaller scale. Such specimens have shown no diminution of fatigue life as compared with otherwise identical control specimens taken from the unstressed ends of the larger specimens.

Although the work of Prof. J. F. Baker and others at the Department of Engineering, University of Cambridge, on the plastic design of welded steel frames has reached fruition, in that buildings so designed are giving satisfactory service (including the fatigue laboratory already mentioned), full-scale investigations continue to take place. On an outdoor site a full-scale portal frame was shown which had been loaded to destruction. This particular test convincingly demonstrated that the additional stiffening effect of fully encastered feet could be obtained with simple and economical concrete foundations.

In past years the use of welding has made possible the construction of pressure vessels and pipelines to suit exacting operating conditions in the steam, oil and chemical industries. In such cases the technicalities of welding and design are inseparable, and much attention is paid by the Association to stress analysis, particularly with regard to the reinforcement of openings in pressure vessels, and the behaviour of pipeline components such as bends and branches where expansion movements have to be sustained. Tests on a number of such components were on view. Experiments on the reinforcement of openings were represented by a steam drum for stress analysis containing six nozzle openings, each with a different type of reinforcement; a pulsating pressure test on small vessels of about $0\cdot3$ m.^{3} capacity to determine the efficiency of different types of nozzle weld preparation; and a pressure cell in which a portion of plate 3·0 m. × 2·4 m. containing a manhole opening 60 cm. diameter had been tested under hydrostatic pressure, simulating the loading which would be sustained when present in an oil-storage tank 40 m. in diameter. This test could not be made on a smaller scale since it was necessary to determine the reserve of ductility as well as the stress distribution in the plate containing the manhole.

During the year the resistance welding laboratory has been almost completely re-equipped in order to meet new programmes of work. The main acquisition, through a Mutual Security Aid grant from the United States, has been a Sciaky three-phase spot-welding machine of large capacity for use mainly with light alloys. As a result of previously conducted fundamental work on heat flow, it has been proved possible to calculate optimum and electrical and thermal cycles for spot welds in hardenable steels. Electronic timing equipment has now been installed, so that the work may proceed with examination of complex thermal cycles by means of which individual spot welds may be heat-treated immediately after they are made.

Experience in the welding industry has already shown that the ultrasonic probe is a powerful tool for non-destructive testing, and one which is often more discriminating than radiography. The two methods may best be described as complementary. Nevertheless, the technique for ultrasonic testing is not easily acquired or taught, and the work of the Association is directed towards the choice of the best methods for examining particular designs of welded joints, while using commercially available equipment. Illustrations were on view of the success which has been achieved with quite complex welded joints, including fillets.

In spite of the research effort which has been expended, brittle fracture still takes a certain toll of steel structures fabricated both by welding and riveting. The use of steels with improved notch toughness can undoubtedly reduce the hazard; but the contribution to safety of better methods of fabrication cannot be ignored. In this direction the Association is investigating problems of the mechanics of such fractures. A new galvanometer was shown by means of which it has been possible to measure the surface energy of a propagating fracture by detecting the plastic-flow heat which is evolved. In this string instrument, which is used with thermocouples, extreme sensitivity has been achieved without high electromagnetic damping by using a very small controlling field, and suspending the strings in a deep catenary to secure the minimum tension. The instrument is being used for studying the influence of stored elastic energy from residual welding stresses on the propagation of fractures in notch-brittle steels. For this purpose, since it is impossible to secure complete residual stress systems other than in wide plates, a 600-ton tensile testing rig has recently been constructed and was on view. This rig was designed by Association investigators and donated by a member firm. Calibration of each of the four hydraulic-loading capsules in the rig was carried out in a Baldwin 180-ton universal testing machine which has recently been acquired through Mutual Security Aid funds.

PHYSICAL AND CHEMICAL ASPECTS OF BASIC MECHANISMS IN RADIOBIOLOGY

A VERBATIM report has been prepared on an informal conference of physicists, chemists and biologists held during May 7–9, 1953, at Highland Park, Illinois, to discuss the interaction of radiation and biological systems in its basic aspects[*]. The foreword emphasizes that "There was no attempt to make the discussions comprehensive; but rather topics of current interest were discussed and analysed". There are five main sections. The first two, dealing with the energy transfer from radiation to matter, were introduced by Robert L. Platzman, of Purdue University. The mechanisms of energy degradation and chemical change and effects of secondary electrons were considered in Section 3, which was introduced by John L. Magee, of the University of Notre Dame. Discussion of the effects of electronic excitation in Section 4 was introduced by Henry Linschitz, of Syracuse University. The final section, which is headed as "Summary: Importance of Radiation Chemical Effects in Radiobiology", was introduced by Martin D. Kamen, of Washington University Medical School, and is, in some ways, the most interesting part of the whole proceedings. The list of references to the individual sections are collected at the end of the papers and deal mainly with work published during and since 1950.

The presentation in the form of a verbatim record, which appears to be very well edited, is a useful way of treating a subject in which there is so much that is problematical. The book deals with those problems which everyone working in these various fields discusses repeatedly, usually without definite conclusions. Probably no single reader will be able to understand the whole of the discussion. The uncertainty of knowledge of the basic physico-chemical mechanisms involved and lack of the necessary experimental evidence is emphasized repeatedly, and often interesting suggestions for further experimental work arise in the course of the discussion.

The basic lack of knowledge is emphasized in connexion with the value of W, the mean energy expended per ion pair. It is useful to quote from p. 5: "All this has a strong moral in radiobiology, and it is one which even the physicist has often taken too lightly . . . namely, that one really knows virtually nothing about the value of W to apply for tissue. Even with a wholesome amount of grains of salt, it seems highly doubtful that this quantity has any present significance in radiobiology". It is interesting that recent experimental evidence tends to confirm Fano's approximate theory of W. Mention is made (p. 2) of the work of Lindhard and Scharff on the theory of stopping-power. The uncertainty of the position concerning the experimental evidence for the stopping-power of α-particles by liquid water is mentioned. Attention is directed to the interesting experiments of Ageno (p. 14) and the whole problem of energy transfer. A practical point of interest is made on p. 19 where Fano points out that, if a 1-MV. photon strikes a water surface, the probability of its emerging back out again is of the order of one-third. On p. 68 Platzman refers to his earlier statements at the Oberlin conference and, in particular, that the whole subject of ionization is very vague in liquid water. On p. 67 there is an interesting discussion on stable, long-lived excited states of water, and the problem of the linear HOH molecule in a triplet state with low energy is discussed.

---

[*] Physical and Chemical Aspects of Basic Mechanisms in Radiobiology: Proceedings of an Informal Conference held at Highland Park, Illinois, May 7–9, 1953. (Publication 305 of the National Academy of Sciences: Division of Physical Sciences of the National Research Council.) Edited by John L. Magee, Martin D. Kamen and Robert L. Platzman. Pp. vii+145. (Washington, D.C.: National Research Council, 1953.) 1 dollar

At the end of the section on electronic excitation, the important problem of the nature of radiomimetic action is discussed; but no real conclusion is reached as to its mechanism. Attention is directed to the work of A. Kellner (*J. Bacteriol.*, 65, 252; 1953) on the growth, respiration and nucleic acid synthesis in ultra-violet irradiated and in photo-reactivated *E. coli*, the deoxyribonucleic acid synthesis being stopped immediately after irradiation and restarted after reactivation. The problem of triplet states with the possibility of long-lived states in complex molecules is discussed again on p. 115. Of particular interest is the discussion on the effects of radiation on the unfolding of proteins and the mechanism of building of adaptive enzymes. The important problem of oxygen effects is not discussed explicitly, and I would like to suggest that this is a problem which might engage the attention of similar conferences.

The book as a whole is very stimulating and should interest physical chemists and physicists, in the important experimental and theoretical problems arising in connexion with the effects of ionizing radiations on the complex systems in aqueous solution which must be studied as a foundation for the understanding of the biological actions of radiations. A conference such as this is obviously of the greatest value to the participants, and one must be grateful that a report such as this is now available.

J. S. MITCHELL

CURRENT TRENDS OF GENETICAL RESEARCH IN HUNGARY

By ANNE McLAREN and DONALD MICHIE
Department of Zoology, University College, London

WE recently had an opportunity of visiting a number of laboratories in Hungary in which genetical research is in progress.

Our first visit was to Prof. Györffy, who directs the Hungarian Academy of Sciences' Institute of Agrobiology in Budapest. A major activity of the Institute at present is the investigation of possible genetic effects produced in young plants by vegetative contact with partners of contrasting genotype. For example, it has been claimed by Michurin (see Waddington[1]) that interspecific crosses which are normally difficult or impossible to obtain can be facilitated by previous grafting between the intended sexual partners. Working with tobacco species, Györffy has found that this method, which has been termed 'vegetative approximation', is strikingly effective in crosses of *Nicotiana glauca* with *N. tabacum* and *N. rustica*, but without effect in crosses between *N. tabacum* and *N. alata*.

Györffy has also used *N. tabacum* for investigating claims of 'vegetative hybridization' made by French and Russian workers (for example, Daniel[2], Glushchenko[3]). It is suggested that, in the seed generation obtained by selfing a grafted plant, variant forms sometimes appear with characters apparently derived from the stock on to which the parent was grafted. In Györffy's experiment spines appeared on the capsules of tobacco plants which had been grafted on to *Datura*. A weaker expression of the modification appeared in the seed generation, but not in subsequent generations. Györffy intends to publish in due course an account of all the recent tobacco work of this Institute.

A large-scale experimental attempt to obtain 'vegetative hybridization' by intervarietal grafting in tomatoes was also undertaken; but no visible modifications appeared either in the grafted plants or in their descendants. Biochemical analyses are now in progress to determine whether the results are also negative in respect of 'physiological' characters. Györffy has also been encouraged by Felföldy's recent positive results (see below) to embark on a new attempt with starting-varieties, which he is now preparing, differing in as many characters as possible.

In addition, a laboratory for the genetics of micro-organisms has recently been set up in the Institute. Pontecorvo's work on heterokaryosis is being followed up in *Penicillium*; a method for prolonging the haploid phase in yeasts is being used for investigations on directed mutagenesis; and studies on the transfer of heritable properties by killed cells in *Rhizobium* are being made. This work is in part designed to throw light on 'vegetative hybridization', in the belief that heritable effects of the host upon grafted plants may be analogous to the phenomena of 'transduction' (see Stocker, Zinder and Lederberg[4]) or 'transformation' (see Avery, McLeod and McCarty[5]) in bacteria.

In search of further information on tomato-grafting experiments we visited Dr. Felföldy in the recently founded Botanical Department of the Biological Research Institute at Tihany on Lake Balaton.

The results of his experiment, up to and including the seed generation, have been published in English[6]. The present remarks include some additional material.

Of the six possible scion-stock combinations obtainable with the three varieties Pruniforme, Oxheart and

Table 1. CLASSIFICATION FOR MENDELIAN CHARACTERS OF THE SEED GENERATION OBTAINED BY SELFING GRAFTED AND CONTROL PLANTS. The convention *A/a* denotes intra-plant variation in the character

Parental plants	Phenotypes in the seed germination	No. of fully classified plants	Subsequent behaviour in five generations of selfing
Oxheart (control)	*R y o n f*	40	Bred true
Oxheart grafted on Golden Apple	*R y o n f*	18	Bred true
	R y O N f	12	Continued to segregate
	R Y O/o N F/f	1	Continued to segregate
	R Y O N F/f	5	Continued to segregate
	Perished	4	
	Total	40	
Golden Apple (control)	*r Y O N F*	40	Bred true
Golden Apple grafted on Oxheart	*r Y O N F*	32	Bred true
	r Y O N f	2	Reverted to *r Y O N F* in F_2
	R/r Y O N f	6	Bred true
	Total	40	

R = red, *r* = yellow (flesh). *Y* = yellow, *y* = colourless (skin). *O* = short, *o* = long (fruit shape). *N* = normal, *n* = nipple-tipped (fruit-shape). *F* = normal, *f* = fasciated (many-chambered in cross-section)

Golden Apple, only the two reciprocal combinations of Oxheart with Golden Apple showed any striking effects of the treatment. These two varieties differ in five major Mendelian characters; but the modifications were confined in the graft generation to an increase of sugar-content and luxuriance in the grafted plants as compared with self-grafted controls. But when the grafted plants were selfed, variant forms appeared in the first seed generation showing characters apparently derived from the stock. Data are given in Table 1 (notation based on Boswell[7]).

In addition, changes in foliage type and in several physiological characters appeared in the seed generation. Dr. Felföldy has concluded that the phenomenon of 'vegetative hybridization' is conditional upon the particular pair of varieties chosen to act as stock and scion, and that the optimal circumstance is that the two varieties should differ in as many physiological properties as possible. He suggests that this may throw light on the negative results obtained by some other workers (see, for example, Sachs[8]). But Dr. A. J. Bateman informs us that at the John Innes Horticultural Institution he obtained negative results from a similar experiment starting with seed supplied by Dr. Felföldy. Next year Dr. Felföldy himself plans to repeat the experiment and to make a concomitant study of sexual crosses between the same varieties.

In the same Institute we spoke with Dr. Fabian, who is working on mammalian genetics in collaboration with Drs. Csik and Stohl. Studies (in the press) have been made by Fabian on the inheritance of morphological characters in reciprocal crosses between *Mus musculus domesticus* and *Mus musculus spicilegus*. Significant evidence of maternal effects was found for skull dimensions, depth of nasal groove, and the ratio of tail to body-length. Heterotic effects were noted in skull-length, body-length and total weight.

Fabian has also been crossing wild rabbits with the 'Belgian' domesticated variety, and has observed a significant maternal effect on skull size in reciprocal crosses. With the object of seeking parallels between phylogenetic and ontogenetic adaptations, studies are now proceeding on the effects of conditions of rearing upon biochemical characters for which the two parent populations differ.

We were able to examine other work on animal breeding and genetics in the Institute of Small Animal Husbandry at Gödöllő. Here most of the genetical projects are still in a preliminary stage.

Dr. Mészáros, from the Institute of Animal Husbandry in Budapest, is injecting sperm from various poultry breeds, and also duck and turkey sperm, into the albumen of fertile eggs of White Leghorn hens on the second day of incubation. It is believed that specific nucleoproteins carried in by the additional sperm may have detectable and specific effects on the course of embryonic development.

An attempt is being made using Rhode Island Reds and White Leghorns to follow up Bratanov's[9] report that the offspring of White Leghorn hens which had been transfused with blood from turkeys were larger and faster-growing than control chicks, and also that some showed pigmentary changes.

Dr. Mészáros also told us that he is using blood transfusion between sheep and goats as a method of 'vegetative approximation', having visited Bratanov's laboratory in Bulgaria and seen live sheep–goat hybrids said to have been obtained by this procedure (for previous attempts, all unsuccessful, to obtain viable hybrids, see Gray[10]). In the same Department, Mr. Piko is using blood transfusion in studies of duck–goose and hen–turkey hybridization.

Dr. Mészáros is also directing all work conducted on artificial insemination in Hungary, where the number of cows artificially inseminated is expected to rise this year from 30,000 to 50,000, and of mares from 65,000 to more than 70,000. In connexion with this work he has made the observation that the fertilization-rate in cattle is increased some 15 per cent by using a mixture of sperm from two different bulls of the same breed. He has evidence that the effect is due to an increased motility of the sperm when in contact with seminal fluid from a genetically different donor. The same effect has been observed in horses and sheep.

Hungarian genetical workers whom we did not visit include Prof. Horn, of Debrecen University, who is making endocrinological studies of the sterility of the economically valuable Peking × Muscovy duck hybrid, and Academician Sedlmayr, who claims to have transferred the heritable character 'anthocyanin-less' by intervarietal grafting in sugar-beet.

All the genetical workers whom we met shared the sense of regret which is widely felt in Britain at the recent lack of communication and understanding between the split halves of the international genetical fraternity. It is in the hope of contributing something towards the re-establishment of this communication that we have prepared this brief and incomplete survey.

BRITAIN'S FORESTS

THE Forestry Commission is producing a series of booklets on "Britain's Forests", two of which deal respectively with the forests at Glentress and Drumtochty*.

Glentress Forest, close to the old Border town of Peebles, was one of the first planting projects in Scotland by the Forestry Commission through the acquisition from the Haystoun Estate of what is now the oldest portion of Glentress Forest, in co-operation with the Department of Agriculture, which was then setting up a land settlement scheme for ex-Service men. Work began there in 1920, and Glentress now includes more than two thousand acres of the hill slopes. The old woodlands and upper hill slopes amounting to 873 acres in all were taken over by the Forestry Commission. Most of these lands lie in the Eschiels of Glentress valley at the eastern end of the forest extending down to the banks of the Tweed; but the braes of Ven Law just behind the town of Peebles were also included. At that date about three hundred acres carried woodland, mostly European larch planted during 1903–5, while the rest was either former woodland that had been cleared of trees or hill ground suitable for afforestation.

---

* Britain's Forests. Glentress: pp. 18; 1s net. Drumtochty: pp. 20; 1s 3d net. (London: H.M.S.O., 1953.)

In 1932 the forest was extended by the addition of about a thousand acres of ground on the north-west in the Soonhope or Shielgreen Glen. The 1903 larch plantations around Eschiels had to be felled during the Second World War. The Forestry Commission has been planting mainly Scots and Corsican pines, Norway and Sitka spruces, Douglas fir and both European and Japanese larches. Thinnings have been already commenced in the older plantations, necessitating the construction of additional roads, so there is plenty of work demanding labour in the area. A forester's training school was established there in 1945, but was moved in 1953 to Faskally, near Pitlochry. The pamphlet is well illustrated.

Drumtochty Forest is another of the Forestry Commission's forests thus described. The traveller who passes through the Howe o' the Mearns, either by road or rail, comes within a few miles of Drumtochty, and if he looks to the west he will see the new forest clothing the slopes of Strathfinella Hill. Moreover, the Glens o' Drumtochty, in the heart of the forest, is on a well-known beauty spot, visited every summer by thousands of tourists; and, indeed, the whole of Kincardineshire, though small, is rich in contrasts by virtue of the high heather-clad Grampians which come down almost to the sea at Stonehaven. The forest is situated on the south face of the Grampians, extending now to 3,340 acres, with 2,400 acres of thriving woodlands established on land too poor for agriculture. It looks out over the Howe o' the Mearns, a fertile hollow famed for its rich harvests of grain and potatoes and its fat cattle. Beyond the Howe to the east stands a low ridge of sheltering hills bordering the rugged coast of the North Sea with its little fishing villages hidden away below the cliffs.

The main routes from the south, which come up the great valley of Strathmore from Perth, traverse the Howe on the way to Stonehaven and Aberdeen. Most of the planting was done between 1927 and 1937. Larches were planted, of which the Japanese and the hybrid have done best on slopes up to a thousand feet. For the moister ground the Norway spruce and Sitka spruce are used, the former where spring frosts are likely to be severe. At lower levels in the glens *Abies grandis* and *A. nobilis*, Douglas fir, western red cedar and the western hemlock have been used; also the Serbian spruce *Picea omorika*. Planting is now giving place to the harvesting of the thinnings from the older plantations, and a first return is being obtained for the outlay. This pamphlet is also well illustrated.

COCOA FERMENTATION

By R. V. WADSWORTH and G. R. HOWAT

Cadbury Brothers, Ltd., Bournville

Proposed Method for fermenting Small Quantities

An attempt has been made to solve the problem of the fermentation of small quantities of cocoa beans. A solution to the problem is particularly urgent at the present time when botanists have made available a large number of new varieties of cocoa. What has been lacking is a satisfactory method of fermenting beans from only one or two pods of each variety, to enable an early and accurate assessment to be made of their quality and acceptability to chocolate manufacturers.

For our experiments, pods of West African Amelonado cocoa were flown from the Gold Coast by commercial airline. Usually they arrived at Bournville about 24–30 hr. after leaving Accra. On arrival the pods were swabbed with a solution of a quaternary ammonium compound to remove surface moulds and other organisms. Tests for viability were made on a few beans by staining technique[1] and by germination tests. It was found that no chocolate flavour could be developed from dead beans, and the time of death was an important factor.

Two methods of fermentation were developed. In the first method an apparatus similar to that described by De Witt[2] was used. The pods were opened under aseptic conditions and the beans were sprayed with a mixed culture of a yeast, *Hansenula anomala*, and an acetic acid producing organism, *Bacillus orleanense*.

Knapp (ref. 3, pp. 17, 30) states that both these organisms are found frequently in commercial fermentations. The inoculum was about 20 million organisms suspended in 10 ml. of Ringer's solution. In accordance with the practice adopted in good commercial fermentations, the beans were well stirred every second day.

Fig. 1 shows the fermentation curve aimed at using this method. It will be noted that during the first 3¼ days the temperature should not exceed 38° C. During the last three days the temperature should be about 50–51° C.

At the end of the fermentation period, the beans were dried in a cabinet maintained at a high humidity to simulate West African conditions. Heat was supplied by a 100-W. electric light bulb. The temperature was not thermostatically controlled and it varied between 45° and 50° C. Under these conditions, drying to a moisture content of about 6 per cent took five or six days.

Beans prepared by this method and using the temperature limits shown in Fig. 1 were generally brown in colour and had cotyledons with an open texture. A few beans showing some purple colour in the cotyledons were found in most of the experiments. It was found that the beans from these fermentations, after roasting and shelling, could be made into chocolate with a good chocolate flavour.

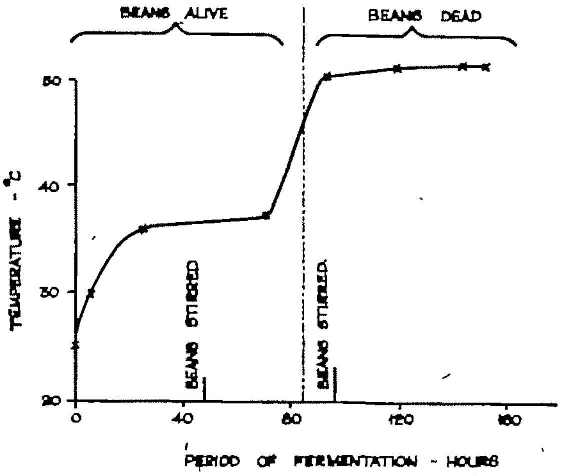

Fig. 1

The second method involved the use of 'aseptic fermentations'. In these, the beans were maintained at any desired temperature in a water-bath or incubator. The pulp was not removed; but the beans were sprayed with a very dilute solution of a quaternary ammonium compound to prevent the growth of organisms in the pulp during 'fermentation'. This method is capable of general application, and it is independent of the chance presence of desirable (or undesirable) micro-organisms in the atmosphere or the use of pure cultures. Suitably modified, we have been able to ferment successfully single beans by this method. In our later experiments the aseptic method was used exclusively, and we consider it less liable to variation than the traditional method.

Details of the aseptic method are as follows. The beans are removed from the pods under aseptic conditions and placed in sterile glass vessels. If the beans from two or three pods are being fermented, tall 600-ml. beakers are suitable. The beans are then sprayed with a solution containing 300 p.p.m. of a quaternary ammonium compound. The beakers are fitted with false bottoms prepared by placing inverted watch glasses on a framework of glass rod. Any liquid produced during 'fermentation' consequently drains away from the beans. The top of each beaker is covered with several thicknesses of aluminium foil and this is kept in place with a tight rubber band.

The beakers are placed in a water-bath or incubator kept at a temperature of 35° C. and allowed to remain there for a period of 84 hr. (3½ days). During this period a considerable volume of carbon dioxide gas is produced and it is essential that this should be removed. It can be done in one of two ways. A quantity of potassium hydroxide solution can be placed under the watch glass at the bottom of the beaker, or the beans can be thoroughly stirred after 24, 48, and 72 hr., and at 84 hr. The first method is probably the better; but it will be remembered that in no circumstances should the potassium hydroxide solution come into contact with the beans.

The beaker containing the beans is then transferred to a water-bath or incubator at 50° C. and kept at this temperature for a period of 72 hr. (3 days). Although production of carbon dioxide at 50° C. is limited to the first few hours (until the death of the bean), it is desirable that even this small quantity of gas be removed. This can be done either by stirring after 24 hr. at 50° C. or by the use of potassium hydroxide solution.

At the end of the period the 'fermented' beans are plump, and when cut exude a small quantity of dark brown liquid. The cotyledons are open and can readily be separated from each other. They are a pale watery purple colour, possibly with a background of brown.

The beans are now transferred to a drying cabinet and dried under the same conditions as those fermented naturally. When dry, the beans will be found to have a loose shell and, on cutting, the cotyledons will be found to be dark brown in colour and to have an open texture. After roasting and shelling they can be made into chocolate which has a good chocolate flavour.

Factors Involved in Fermentation

Recent experiments on the fermentation of small quantities of West African Amelonado cocoa in these laboratories have directed attention to several aspects of the changes involved in fermentation which do not appear to have been noted previously. At least three factors play a part in the development of chocolate flavour.

The first is the germination processes in the bean during the first part of fermentation. This seems to have been accorded no importance in previous work. Indeed, Knapp (ref. 3, p. 134) states that "until the bean is killed no change takes place in the interior, so that it is desirable to raise the temperature rapidly to accomplish this". Our experiments have shown that this view is incorrect. Beans which have been killed by cold—24 hr. in a refrigerator at 1–1·5° C.—and then fermented using pure cultures of organisms, or prepared by the aseptic method, do not produce anything resembling a chocolate flavour. Also, when beans are maintained at a temperature of 50° C. for several days without a prior period at a germinating temperature, no chocolate flavour is developed.

The second factor is that the beans must be maintained at a temperature of about 50° C. for several days after the initial germination period. If this is omitted and the beans maintained at around 35° C. for five days, they give either a mild flavour which is reminiscent of caramels, or have a slight liquorice character when made into chocolate. In addition, the colour of such beans after drying is not brown, it is purple. At higher temperatures the degree of purple remaining in the finished beans is less; but it is our experience that even when a temperature of 45–46° C. is maintained instead of 50° C., some purple background is present and there is bitterness in the chocolate produced. It should be noted that the temperatures used in our aseptic fermentations approximate roughly to those observed in good commercial fermentations. The nature of the changes produced during this period has not been studied by us in detail. They are, however, undoubtedly associated mainly with changes in the polyphenols, as has been noted by Forsyth[4].

The third factor is the removal of carbon dioxide from the air around the fermenting beans. It is well known, of course, that carbon dioxide is produced in fermenting cocoa. There appears, however, to be no published record that large quantities of carbon dioxide are produced by the bean itself—as distinct from fermentation of the pulp—during the early stages of fermentation.

Our experiments have shown that when fermented under aseptic conditions, the carbon dioxide content of the atmosphere around the cocoa beans may rise as high as 90 per cent during the first three days. In fermenting single-bean samples, we have found that a single cocoa bean (dry weight 1·2 gm.) produces up to 10 ml. carbon dioxide at N.T.P. during the early stages of fermentation. There is apparently no liberation of carbon dioxide after the bean dies.

In certain experiments an atmosphere of carbon dioxide was maintained around the beans during the period they were held at 50° C. or during drying. In each case it was found that the chocolate prepared from such beans was unpleasant and had no chocolate flavour.

It is interesting to note that in good commercial fermentations the practice is to turn the cocoa or to mix it every second day. This will have the desired result, if properly done, of removing the carbon dioxide.

Two other points have interested us. One is that during fermentation very little change takes place in the *p*H of the cotyledons. In our fermentations, using pure cultures of organisms, we found that the *p*H of the pulp fell from about 4 to 2·5. There was no similar fall in the *p*H of the cotyledons; here a slight reduction, from 5·5 to 5, was all that was noted.

This point is of particular interest in that it has been frequently suggested that the flavour of fermented beans is affected by the character of the fermentation which it has undergone, and that the esters formed during fermentation may permeate the testa and pass into the cotyledons. In the light of our findings, this seems unlikely.

The other point which interested us was the gap in temperature that exists between the thermal death-point of the organisms which occur in commercial fermentations and the maximum temperature recorded in a fermenting heap. The thermal death-point of most organisms occurring in commercial fermentations is 43–44° C. as observed by Rombouts[5]. The maximum temperature recorded in good fermentation practice is, however, usually 50–51° C. It appears possible that the heat produced by the enzymic processes in germination is sufficient to raise the temperature of the whole fermenting mass sufficiently to bridge the gap between 44° and 51° C.

A fuller account of these experiments is in course of preparation and will be published elsewhere. We are indebted to the Directors of Cadbury Brothers, Ltd., for permission to publish this communication.

PHOTOSYNTHESIS BY ISOLATED CHLOROPLASTS

By PROF. DANIEL I. ARNON, DR. M. B. ALLEN, and DR. F. R. WHATLEY

Department of Plant Nutrition, University of California, Berkeley

THE many attempts to reconstruct photosynthetic events by systems less organized than whole green cells have met with success in only one area: the photolysis of water by chloroplast preparations resulting in the evolution of oxygen[1] (the Hill reaction). Evidence has now been obtained that whole chloroplasts, unaided by other cellular particles, have the ability to carry out two other photochemical reactions outside the living cell: (*a*) carbon dioxide fixation, and (*b*) photosynthetic phosphorylation, a term which we use for the conversion of light energy into the high-energy phosphate bonds of adenosine triphosphate (ATP), without the participation of respiration.

Although there are valid reasons for believing that the functioning photochemical mechanism in isolated chloroplasts, as measured by the evolution of oxygen, is the same as in the intact cell[2], there is uncertainty as to the manner in which light energy captured by chloroplasts is linked to carbon dioxide reduction. Until now, isolated chloroplasts appeared to differ from intact cells by being unable to link the photochemical evolution of oxygen to carbon dioxide fixation even when the latter was measured by the sensitive tracer carbon technique[3]. The Hill reaction proceeded only in the presence of non-physiological electron or hydrogen acceptors such as ferricyanide or quinone.

A step forward was the finding that, under proper conditions, illuminated, isolated chloroplasts can reduce the well-known physiological electron carriers triphosphopyridine nucleotide (TPN) and diphosphopyridine nucleotide (DPN)[4]. This permitted the linking of the Hill reaction to many enzymatic reactions, including carboxylations, which are dependent on reduced pyridine nucleotides. Indeed, the expectation that any enzyme system which uses reduced tri- or di-phosphopyridine nucleotide can do so whether the reduced coenzymes are produced by respiration or by illuminated chloroplasts was amply documented, particularly by the work of Vishniac and Ochoa[5]. These workers have also shown[6] that photochemically reduced diphosphopyridine nucleotide could be reoxidized by mitochondria from non-photosynthetic tissues and bring about the synthesis of adenosine triphosphate by an oxidative phosphorylation of the type observed by Lehninger[7].

Concepts, based on experiments with model enzyme systems, assigned to chloroplasts *in vivo* the limited functions of photolysis of water and the transfer of electrons and hydrogens to suitable acceptors, which were assumed to be pyridine nucleotides[8]. Carbon dioxide fixation proper and the conversion of light energy into the pyrophosphate bond-energy of adenosine triphosphate would, in this view, be carried out by mitochondria and soluble enzymes situated outside the chloroplasts. This concept was made plausible by the finding that in green leaves the malic enzyme, mediating the reductive carboxylation of pyruvate to malate, was in the cytoplasmic fluid[4,9,10]. Other carboxylases[10] as well as an important enzyme of the glycolytic cycle, glyceraldehyde phosphate dehydrogenase[11], were also found in the cytoplasmic fluid of green leaves rather than in the chloroplasts.

Our present findings, however, speak against this concept. Since washed chloroplasts were found to have the capacity, without the addition of other enzymes, to use light energy for adenosine triphosphate synthesis and carbon dioxide fixation, it follows that these particles contain the enzyme systems and at least most of the co-factors concerned in these reactions. The only added compound which gave consistently large increases in both photosynthetic phosphorylation and carbon dioxide fixation was ascorbic acid. The addition of di- or triphosphopyridine nucleotide, uridine triphosphate, cocarboxylase, thioctic acid or a mixture of thioctic acid and cocarboxylase was without effect on carbon dioxide fixation or photosynthetic phosphorylation. In the light of our present evidence, isolated chloroplasts emerge as remarkably complete cytoplasmic structures, equipped to carry out not only oxygen evolution but also carbon dioxide fixation and the conversion of light into chemical energy.

In setting out to investigate light reactions of isolated chloroplasts with reference to photosynthesis, our basic premise has been that only those chloroplast preparations which possessed the capacity for photolysis of water, as measured by oxygen evolution, were desirable objects of study. Isolated chloroplasts lacking this capacity are, so far as we know, incapable f the primary conversion of light into chemical nergy, and would therefore not be expected to articipate in reactions involving carbon dioxide ixation. The dependence of phosphorylation and arbon dioxide fixation in whole chloroplasts on their apacity for photolysis was demonstrated by the use f *o*-phenanthroline, a powerful inhibitor of photoysis[12,13]. Chloroplasts inhibited in this manner were n our experience unable to synthesize adenosine riphosphate or to fix carbon dioxide. It is therefore ifficult to interpret the relation to photosynthesis of arbon dioxide fixation by those chloroplast preparaions reported by Fager[14], which retained only a egligible capacity for oxygen evolution.

Our first experiments showed (Table 1) that while he capacity for photolysis is a prerequisite, it is not he sole condition for active photosynthetic phoshorylation and carbon dioxide fixation. Whole pinach chloroplasts, prepared in 0·5 *M* glucose or 0·35 *M* sodium chloride, were found capable of carrying out all three reactions. Chloroplast fragments, which in these (Table 1) and previous experiments[13] retained an unimpaired capacity for photolysis, showed only feeble photosynthetic phosphorylation and practically no light-induced carbon dioxide fixation. Whole chloroplasts were therefore used in all subsequent experiments. The ratio of light to dark fixation was used as an index of photosynthetic activity. With good preparations of chloroplasts the ratio averaged about 160 for carbon dioxide fixation and 20 for phosphorylation.

Table 1. PHOTOLYSIS, PHOTOSYNTHETIC PHOSPHORYLATION AND CARBON DIOXIDE FIXATION BY CELL-FREE PREPARATIONS

All three reaction mixtures were in 3 ml. of 0·13 *M* tris (hydroxymethyl) amino methane, *p*H 7 2, and 0·35 *M* sodium chloride. Reaction time, 60 min. Temperature, 15° C. Gas phase, air. Special components were: photolysis–chloroplast material containing 0·5 mgm. chlorophyll and 7·4 μM *p*-benzoquinone; photosynthetic phosphorylation–chloroplast material containing 2 mgm. chlorophyll, 10 μM sodium ascorbate, 10 μM adenylic acid, 20 μM of a mixture of sodium and potassium phosphate, *p*H 7·2, containing 290,000 counts per minute (c.p.m.) of phosphorus-32. Carbon dioxide fixation–chloroplast material containing 2 mgm. chlorophyll, 10 μM sodium ascorbate, 20 μM of a mixture of sodium and potassium phosphate, *p*H 7·2, and 1·5 μM sodium carbonate containing *c.* 1 5 × 10⁶ c.p.m. of carbon-14

Preparation	Photolysis (mm.³O₂/hr./mgm. chlorophyll)	Photosynthetic phosphorylation (c.p m. organic ³²P)		Carbon dioxide fixation (c.p.m. ¹⁴C)	
		Light	Dark	Light	Dark
Leaf homogenate	340	4,900	3,140	60,600	3,140
Intact chloroplasts	480	4,250	950	52,000	288
Chloroplast fragments	400	1,100	300	1,100	1,000

Our results suggest an increasing order of complexity for the three photochemical reactions of isolated chloroplasts. Photolysis could be carried out by preparations incapable of photosynthetic phosphorylation and carbon dioxide fixation. In turn, photosynthetic phosphorylation was found to proceed unimpaired in the presence of potassium hydroxide when the partial pressure of carbon dioxide was extremely low. Carbon dioxide fixation, however, has so far been observed only under conditions which were compatible with active photolysis and phosphorylation.

The three photochemical reactions were separable by differential inhibition and by variations in the technique for the preparation of chloroplasts. Chloroplasts isolated in ethylene glycol retained their capacity for photolysis and photosynthetic phosphorylation, but fixed practically no carbon dioxide. Using chloroplasts prepared in glucose or potassium chloride, we found that 2,4-dinitrophenol (8×10^{-4} *M*) was a strong inhibitor of both carbon dioxide fixation and phosphorylation, but that its effect on photolysis was rather mild. Iodoacetamide (2×10^{-4} *M*) inhibited carbon dioxide fixation about 97 per cent but had practically no effect on photosynthetic phosphorylation. As shown in Fig. 1, *p*-chloromercuribenzoate (CMB) was a strong inhibitor of carbon dioxide fixation, a less effective one of photosynthetic phosphorylation and had practically no effect on photolysis. This inhibition suggested the participation of sulphydryl groups in the chloroplasts. However, attempts to reverse the inhibition by the addition of cystein or glutathione were inconclusive since these compounds were themselves inhibitory.

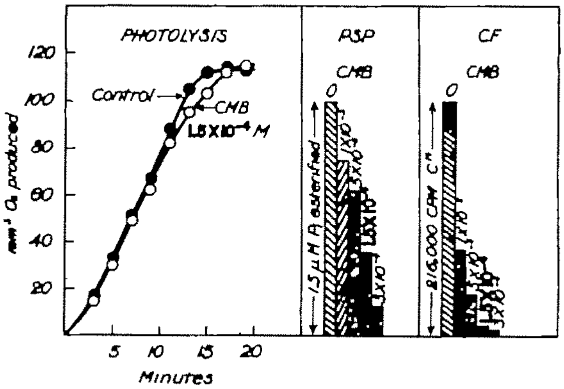

Fig. 1. Effect of *p*-chloromercuribenzoate (CMB) on photolysis, photosynthetic phosphorylation (PSP) and carbon dioxide fixation (CF) by isolated chloroplasts. Experimental conditions as in Table 1, except that gas phase in photolysis and carbon dioxide fixation was nitrogen, and phosphate was omitted in the latter reaction mixture

An important difference between photosynthetic phosphorylation and carbon dioxide fixation was their response to anaerobiosis. As shown in Fig. 2, carbon dioxide fixation was increased under conditions of low oxygen tension, whereas photosynthetic phosphorylation was markedly inhibited. Anaerobic conditions were maintained by flushing the reaction vessels with nitrogen gas and having an 'Oxsorbent' solution (chromous chloride) in the side arm. These conditions would, of course, not exclude the very small quantity of oxygen (1 micromole at most) of photosynthetic origin newly liberated *in situ*.

The addition of adenosine triphosphate or of adenylic acid did not increase carbon dioxide fixation by isolated chloroplasts. A wholly unexpected finding was the inhibition of carbon dioxide fixation by the addition of inorganic phosphate (Table 2). These results suggest a competitive relation between photosynthetic phosphorylation and carbon dioxide fixation by isolated chloroplasts. It

Fig. 2. Effect of anaerobiosis on (a) carbon dioxide fixation and (b) photosynthetic phosphorylation. Experimental conditions as in Table 1, except that phosphate was omitted in carbon dioxide fixation. Anaerobic conditions were provided by nitrogen gas and 0·2 ml. 'Oxsorbent' in the side arm of reaction vessel

seems prudent, however, to defer an interpretation of these data until results are obtained from other experiments now under way. Our chloroplast preparations contained measurable quantities of inorganic and organic phosphate. The identification, now in progress, of the products of carbon dioxide fixation by isolated chloroplasts in the absence of added phosphate should provide pertinent data on the relation between photosynthetic phosphorylation and carbon dioxide fixation by isolated chloroplasts.

Although the dependence upon oxygen of photosynthetic phosphorylation seems well established, the elucidation of the role of oxygen in this reaction must await further experimentation. Photosynthetic phosphorylation is not accompanied by manometrically measurable evolution of oxygen. The accompanying equations represent a tentative scheme of the course of the reaction, in accordance with experimental facts now known.

AMP and P_i represent adenosine-5-phosphate and orthophosphate (labelled with phosphorus-32).

$$(1) \quad H_2O \xrightarrow[\text{chloroplasts}]{\text{light}} 2e + 2H^+ + \{O\}$$

$$(2) \quad AMP + 2P_i + 2e + 2H^+ + \{O\} \rightarrow ATP + H_2O$$

$$\text{Sum}: \quad (3) \quad AMP + 2P_i \xrightarrow[\text{chloroplasts}]{\text{light}} ATP$$

Adenosine diphosphate was found equally effective. The brackets around the oxygen in reactions (1) and (2) are intended to denote that it has not yet been determined whether: (a) oxygen is released in reaction (1) and immediately consumed in reaction (2), or (b) whether the oxygen in reaction (1) represents the formation of some oxidized substance within the chloroplast which is reduced by electrons in accordance with equation (2). In this connexion the recent observation by Lundegårdh[15] of the oxidation of cytochrome *f* in green cells on exposure to light is of special interest.

Adenosine triphosphate was identified as the product of reaction (3) (a) directly, by adsorption on 'Norite' followed by hydrolysis of labile phosphate, and (b) indirectly, using hexokinase and glucose as an adenosine triphosphate acceptor system either during the progress of photosynthetic phosphorylation or following the termination of the reaction and the chemical isolation of adenosine triphosphate. In both cases the product of the hexokinase reaction, glucose-6-phosphate, was identified chromatographically.

The photochemical esterification of inorganic phosphate by chloroplasts, independent of carbon dioxide fixation, provides a mechanism for converting light energy into adenosine triphosphate, without the utilization of energy released by reoxidation of partly or wholly reduced products of carbon dioxide fixation[16]. Both photosynthetic phosphorylation and carbon dioxide fixation by isolated chloroplasts are novel findings which require careful documentation. The conclusions presented here are based on forty-three consecutive experiments with isolated chloroplasts in which photosynthetic phosphorylation and carbon dioxide fixation were observed without a single exception. A full account of these experiments will be presented elsewhere.

This investigation was aided by a grant from the U.S. Public Health Service. [May 19.

Trace Analysis by X-Ray Emission Spectrography

We have used X-ray emission spectrography[1] X-ray fluorescence) for rapid and accurate direct analysis of small quantities of material by a technique resembling that of the familiar spot test[2]. Our results on zinc (Fig. 1) show the simplicity and speed of the method.

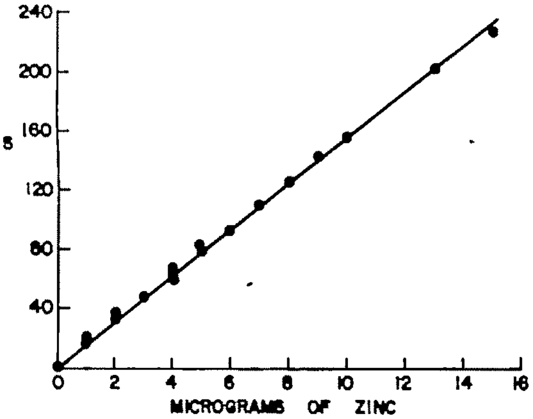

Fig. 1. Counting-rate of zinc $K\alpha$ line for various amounts of zinc on Schleicher and Schuell No. 740*E* ½-inch disks. Samples prepared by placing measured amounts of zinc sulphate solution on the paper and drying to remove the water

The samples containing zinc were dissolved and the solutions dispersed over a well-defined area that could be placed completely in the X-ray beam. As a carrier for the dispersion, Schleicher and Schuell bioassay paper (No. 740*E*) or Whatman's No. 50 filter-paper worked well. The thinness and rigidity of the paper simplified the problem of keeping the sample at the proper place in the X-ray system; other carriers, however, can be used. The intensity of the zinc characteristic $K\alpha$ radiation above the surrounding background gave the direct quantitative measure of the zinc content. Typically, 15·6 counts/sec. of zinc $K\alpha$ radiation per microgram were observed above a background of 49·7 counts/sec. using the bioassay paper. With the filter-paper the background was only 15 counts/sec. The reduced background decreased the time necessary for the detection of 1/30 microgram of zinc from 7 to 2 min. counting time. Different samples of paper gave varying backgrounds, with a standard deviation of 3 counts/sec., which made it possible to determine the larger zinc concentrations without a separate background determination.

Fig. 1 shows the accuracy of the method for numerous samples; the linear range extends to 100 μgm. before absorption effects introduce curvature. The same technique was used for the determination of small amounts of vanadium, copper, iron, silver, bromine, gold, and lead with standard deviations of well under 1 microgram for a determination taking 10 min. or less.

We have increased the sensitivity by counting for longer times. Care is necessary, however, because long-time fluctuation in the X-ray equipment can cause difficulty. Therefore, we have used a commutation method in which the sample and background are counted alternately until the desired number of counts is accumulated.

The samples we used are thin—a microgram of zinc spread over 1 sq. cm. is only 3 atoms or about 10 A. thick; radiation produced in such a thin layer will be essentially unaffected by the presence of other atoms in like quantities. It should therefore be possible to analyse mixtures without concern for the interferences that occur in the X-ray emission spectrographic analysis of bulk materials.

Except for the rather rare overlapping of X-ray lines, the components of mixtures will respond independently, and no previous chemical processing beyond dispersing the sample is required.

Visibility of X-Ray Quantum Fluctuations on Image Intensifier Radiographs

The gain in brightness with an X-ray image intensifier is accompanied by a more or less disturbing effect, namely, the visibility of a kind of visual 'noise', especially when the X-ray intensity is low, the intensification factor of the intensifier is high (greater than 1,000 times) and the optical magnification of the final image large.

In intensifier radiography, in certain circumstances a coarse mottling is observed on the photographic image of the viewing screen. In Fig. 1, four prints are shown of intensifier radiographs (original size 5 mm. diameter) on Agfa Fluorapid film. An object

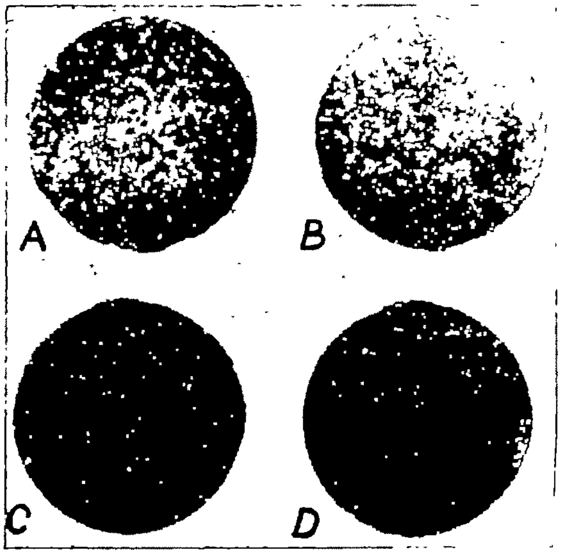

Table 1

Photo	Charge (mA sec.)	Relative exposure time	No. of developed grains per X-ray quantum absorbed
A	0 006	1	32
B	0 030	5	6
C	0·19	32	1
D	0 96	160	0·2

equivalent to 8 cm. of water was placed between the X-ray tube and the image intensifier. The pictures were taken at 67 kV., focal distance 90 cm. The difference between the radiographs is the amount of X-ray energy detected per picture. By varying the speed of the optical system with an aperture, an equal density of 0·75 on the original radiographs was obtained.

In Table 1 are given for each picture the X-ray energy which is proportional to the electrical charge (mA.sec.) through the X-ray tube, the relative exposure times and the approximate number of silver grains per absorbed X-ray quantum. Though the film material and the density were the same, the structure of the pictures is quite different. The mottling of the image decreases with increasing current. The intrinsic film graininess is reached when the number of X-ray quanta necessary for producing one silver grain exceeds 1.

The explanation is as follows: on picture *A*, taken with a small quantity of X-rays, every absorbed X-ray quantum gives rise, due to the intensification, to the development of a cluster of 32 silver grains in the film emulsion. The mottling of the radiograph is determined by a statistical distribution of grain clusters, the dimensions of which are determined by the circle of diffusion of the intensifier X-ray screen. The number of grains in one cluster is given by the last column of Table 1. As the number of clusters per unit area in picture *A* is considerably smaller than the number of separate grains in picture *D*, the grain distribution in picture *A* deviates much more from a homogeneous distribution than that in picture *D*, due to the larger relative statistical fluctuations in the number of clusters.

A similar effect has been observed by Eggert and Schopper[2] when taking full-size radiographs with X-rays of different hardness. The picture with hard X-rays seems to be more grainy than the photo with soft X-rays. This effect, however, is less pronounced than on intensified radiographs, because on an ordinary full-size radiograph only two to three grains are developed for each X-ray quantum of the same energy.

Recently, Cope and Rose[3] published an X-ray noise picture, using a photoconductive pick-up tube.

The visual 'noise' in intensifier fluoroscopy with low X-ray intensity and the coarse mottling in intensifier radiography with small quantities of X-rays, due to the statistical fluctuations in the (relatively small) number of absorbed X-ray quanta, have the consequence that the perceptibility of detail on intensified images and radiographs is limited. This has been predicted by Sturm and Morgan[4] and confirmed experimentally by us[5]. Only by increasing the number of X-ray quanta detected can the perceptibility of detail be improved.

Summarizing, the influence of quantum fluctuations on image-intensified radiographs is such that in certain circumstances (high-speed optics, sensitive film) the picture is much more mottled than corresponds with the normal intrinsic graininess of th photographic emulsion.

Velocity of Electron Pulses

One of us[1] has noted that the velocity of electron has never been measured under conditions which allow no alternative interpretation. A linear velocity of displacement is a necessary inference only when two successive events, departure and arrival, have been observed which are localized and distinct, both in space and in time. In the known determinations with static or periodic deflecting fields one canno discriminate between *transit times* of localized entities and *vibration periods* of extended systems. It appeared therefore, of interest to determine the transit time across a measured distance, of a brief pulse of electrons of known energy. This was achieved by using two deflector gates, which are opened for very brief intervals only by a single surge travelling in a cable with an accurately measurable and adjustable delay time, corresponding to the length of cable, between the opening of the first gate and of the second.

A sketch of the apparatus is shown in Fig. 1. An electron gun directs a fine beam of 2 kV. electrons into the top deflexion chamber. At the start the beam is deflected by a static potential of 1·1 kV on the cable core, so that the gate is closed. The voltage is reversed by a vacuum switch, which sends two travelling waves to the gates. The top gate opens first, at an instant when the potential of the deflector electrode connected with the cable core passes through zero. By using fine apertures, the opening time can be reduced to about 10^{-10} sec. A group of electrons passes through the small exit aperture, and is focused by a magnetic lens on the entrance aperture of the second gate, so that no electrons are lost in the transit. The opening pulse at the second gate is delayed by a length of polythene cable; the delay can be accurately adjusted by means of a sliding branching-point. If the electrons are monokinetic, and if the delay in the cable is equal to the transit time, practically all electrons which have passed through the first gate will also pass through the second. They are collected by a nine-stage beryllium–copper electron multiplier, which we owe to the courtesy of Dr. Alexander Baxter (Cambridge), with a gain of the order 100,000. Using three valve-amplifier stages, pulses of less than fifty electrons could be easily observed on the screen of a cathode ray tube, and the noise-level was so low that spontaneous pulses of this order occurred only a few times per minute.

The results completely confirmed the orthodox expectations. By moving the branching-point, it could be ascertained that about 90 per cent of the electrons arrived within ± 1 per cent of the mean transit time; and the most probable transit time,

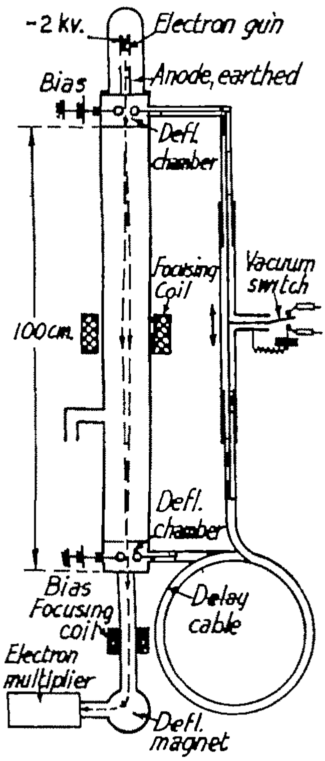

Fig. 1

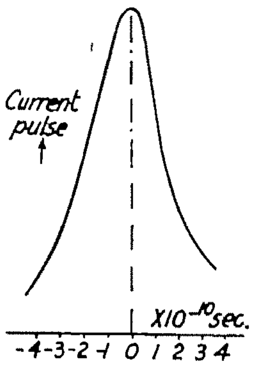

Fig. 2

that is to say, the position of the current peak in Fig. 2, could be ascertained within ± 0·25 per cent. The corresponding delay in the cable agreed with the calculated electron transit time within about 1 per cent, which is inside the error limit due to the calibration of the cable, and of the measurement of the accelerating voltage. The scatter in the electron arrival (Fig. 2) can be accounted for by the fluctuations in the high-voltage source and by the opening characteristic of the gates. The position of the maximum could be ascertained in a range of ± 5 mm. shift of the branching-point, corresponding to a time uncertainty of 3×10^{-11} sec. We estimate that by using a stabilized voltage source, finer apertures and a thirteen-stage multiplier this could be reduced by an order of magnitude. It appears, though, that the experiments, as they stand, constitute a sufficient *a posteriori* justification of velocity measurements using periodic fields.

The apparatus was so devised from the start that, once this confirmation was obtained, it could be used as a velocity spectrograph, and as a chronograph for measuring the time of rise of very steep surges. If in one of the gates the deflecting electrode opposite to the one which is energized by the surge is biased by, say, ± 100 V., the moment of opening will be delayed or advanced by the time which the potential in the wave-front takes to rise by 100 V., and the other gate must be correspondingly delayed or advanced in order to pass the maximum current. It was found that the time of rise for 100 V. in a surge of 2·2 kV. total, initiated by a vacuum switch, was 3×10^{-10} sec., and no significant difference was found between the slope at the top gate and at the bottom gate due to damping by the polythene cable. This figure must be considered as giving a lower limit only for the slope, as no particular care was taken in matching the deflecting chambers to the cable.

Orientation of Apatite Crystals in Bone

From the earliest experiments on X-ray diffraction by specimens of bone, it has been well known that in long bones, for example, femora, the *c*-axes of the hexagonal apatite crystals are preferentially orientated parallel to the long axis of the bone. In regard to sections of bones cut normal to the long axis, no one has reported any preferential orientation of the crystals. In fact, it has been repeatedly stated in the literature that there is no orientation of the crystals in the plane perpendicular to the long axis[1].

During the past few years we have been studying the crystal structure of bones in relation to growth, and as part of this research we have investigated sections cut perpendicular to the long axes of the femora of rats of all ages. The sections were cut near the middle of the bone by means of a section-cutting machine similar to that described by Atkinson[2]. They were approximately 0·006 in. thick and were mounted in a miniature X-ray camera of the Chesley type[3]. In every specimen examined we have found that the apatite crystals are always preferentially orientated with the *c*-axis approximately tangential to the surface of the bone. A systematic investigation was carried out as follows.

A reference line was marked on the collimator holder which also carried the specimen, and a corresponding line was marked on the film. The collimator with specimen attached was mounted on the stage of a microscope and a beam of light passed through the collimator (diam. 0·01 cm.) so that a bright spot of light was seen at the point on the specimen where the X-ray beam would strike. A photograph was taken with a magnification of 18 times, so that for each X-ray photograph the exact spot where the X-ray beam passed through the specimen was known as well as the orientation of the specimen with respect to a reference line on the film. After each X-ray exposure the specimen was moved and another photomicrograph taken until a series of exposures had been taken at points all round the hollow sections.

The 002 powder ring appears as two strong arcs and the position of these arcs moves around the powder ring as the point irradiated moves around the annulus of bone. (The much weaker 004 ring is similar.)

The angle which the line joining the middle of the arcs makes with the reference line was measured on each photograph. This is the preferred direction of the *c*-axis of the apatite crystals. A tracing of the outline of the bone section was made from one of the photomicrographs and the successive points irradiated were marked on it. From each of these points a line was drawn perpendicular to the tangent to that part of the bone surface nearest to the point considered. For each photograph the preferred *c*-axis direction was drawn on the tracing and the angle it makes to the 'radial' lines measured. If the direction of

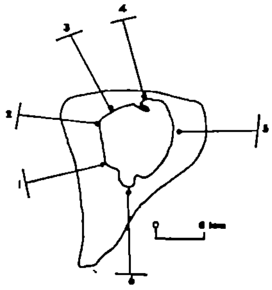

Fig. 1

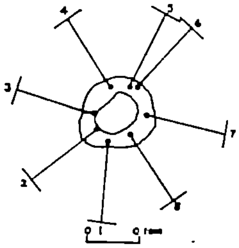

Fig. 2

Fig. 1. Outline of cross-section of rat femur (age 4 months) showing positions where X-ray diffraction photographs were taken and corresponding directions of preferred orientation of c-axes of apatite crystals

Fig. 2. As for Fig. 1 (age 10 days)

preferred orientation is tangential, these angles should be 90°.

Two examples are illustrated. Fig. 1 is a section of a femur of an adult rat (four months) and the angles are respectively as follow:

(1) 90°, (2) 79°, (3) 87°, (4) 83°, (5) 85°, (6) 87°.

Fig. 2 is a section of the femur of a young rat (ten days) and the angles in this case are:

(1) 87°, (2) 88°, (3) 89°, (4) 88°, (5) 90°, (6) 86°, (7) 87°, (8) 89°.

In view of the difficulty of drawing accurate tangents to the non-regular surfaces, it seems well established that the apatite crystals in the cross-section of the rat femora are preferentially orientated with the c-axis tangential to the surface of the bone.

When photographs of a longitudinal section are compared with those of a cross-section, it is clear that the intensity of the 002 arcs in the latter is much less than in the former. It seems, therefore, that in the bone shaft as a whole the majority of crystals are arranged with their c-axes approximately parallel to the long axis of the bone; but of those crystals which are lying with their c-axes in the cross-sectional plane, most are arranged with the c-axes tangential to the surface. Fig. 3 shows X-ray diffraction photographs of (a) a longitudinal section with X-ray beam perpendicular to the long axis, (b) a cross-section of the same specimen with X-ray beam parallel to the long axis of the bone (position No. 3 of Fig. 1); copper $K\alpha$ radiation, specimen-to-film distance 1 cm. The 002 reflexion which shows pronounced arcs in both photographs is inside the strong continuous ring.

We are indebted to Prof. A. Haddow, of the Chester Beatty Research Institute, London, for a supply of pure-line Wistar rats and to Prof. G. H. Bell an Miss M. H. Thomas for providing us with most o the specimens.

Fluorometric Detection and Estimation of Germanium

Fluorometry has become a very important too in the hands of the analytical chemist in recent years not only for the detection but also for the quantitative estimation of several substances, especially those occurring in traces. Nevertheless, very few metals are detected and estimated by fluorometric methods.

No fluorometric test has so far been reported fo germanium. This element has in recent years attained strategic importance on account of its use in the manufacture of transistors and on account of it scarcity. We have now found that traces of germanium give an intense greenish-yellow fluorescence with a solution of resacetophenone in concentrated sulphuric acid or syrupy phosphoric acid under filtered ultra-violet light. No other metal interferes.

Borate gives a blue fluorescence with this reagent, as already reported by Neelakantam and Row[1]. Nitrite, nitrate, fluoride and chromate quench the fluorescence given by germanium in both the sulphuric and phosphoric acid media. Bromide, iodide and chlorate quench the fluorescence in the sulphuric acid medium but not in the phosphoric acid medium. When sulphuric acid is employed, the solution acquires a brownish colour, which deepens on standing.

We recommend the following method for the fluorescence test for germanium. The resacetophenone reagent is prepared by dissolving 0·5–1·0 gm. of the pure substance in 100 ml. of acetic acid. To 3 ml. of this reagent in a quartz test-tube is added 6 ml. of syrupy phosphoric acid. 0·1–1·0 ml. of the germanium solution is now run in and mixed, adding some more syrupy phosphoric acid, if necessary, to make up the total volume to 10 ml. Then the test-tube is kept exposed to ultra-violet light from which all visible light has been filtered out; for this purpose we have used the 'Cenco Black Light' source operating on 220-V. a.c. mains. The intensity of the greenish-yellow fluorescence has been found to vary with the concentration of the germanium ions. The limit of sensitivity is 1 : 10,000 and the limit of identification 100 γ.

Synthesis of (±) Methyl Fluoromalate

The observations of Peters *et al.*[1] that the administration of fluorocitrate resulted in the inhibition of the tricarboxylic acid cycle suggested the synthesis of other fluorinated acids of biochemical interest. In this preliminary communication, we wish to report the synthesis of (±) methyl fluoromalate and fluoromalamide.

Ethyl ethoxalylfluoroacetate, prepared according to Rivett's method[2], was reduced with potassium borohydride (two equivalents) in absolute methanol with vigorous stirring. The temperature of the reaction mixture rose to 50° during the reaction, which was complete after 90 min. Excess dry methanolic hydrogen chloride was added and the filtered solution distilled with repeated addition of methanol to remove methyl borate. The remaining solution was neutralized with lead carbonate, filtered and dried (sodium sulphate). Removal of the solvent furnished (±) methyl fluoromalate (transesterification having taken place during the reactions) as a colourless viscous liquid. The ester gave negative tests for carbonyl groups, a positive test for hydroxy groups and had the following microanalytical composition: C, 40·0; H, 5·8 per cent. $C_6H_9O_5F$ requires C, 40·1; H, 5·1 per cent.

The reduction of ethyl ethoxalylfluoroacetate with lithium aluminium hydride and aluminium *iso*propoxide was also attempted; but preliminary experiments gave much poorer yields of the ethyl fluoromalate.

(±) Methyl fluoromalate was identified by converting it into the diamide with saturated methanolic ammonia for 48 hr. The fluoromalamide was recrystallized from *iso*propyl alcohol (m.p. 160° uncorr.). A mixed melting point with malamide[3] (m.p. 162° uncorr.) gave a depression (m.p. 130° uncorr.). Fluoromalamide exhibited an absorption band at 1,050 cm.$^{-1}$ which was attributed to the C–F bond and gave the following micro-analytical results: found: C, 32·1; H, 4·4; N, 18·8 per cent. $C_4H_7O_3N_2F$ requires C, 32·0; H, 4·65; N, 18·7 per cent.

The results of biochemical assay[4] and details of this work will be published elsewhere. We thank Dr. E. M. Gal for his advice and interest in these experiments.

Reversal and Mechanism of Oxidative Phosphorylation

The importance of reactions in which electron transport from reduced pyridine nucleotides to oxygen is coupled with the formation of adenosine triphosphate from adenosine diphosphate and inorganic phosphate is well recognized by biochemists. Although much pertinent information has been accumulated, no clear picture of the sites and mechanism of uptake of inorganic phosphate coupled with electron transport has yet been obtained. This communication gives some results of exchange reactions of inorganic phosphate labelled with phosphorus-32 and oxygen-18 which may give some additional insight concerning oxidative phosphorylation, together with a brief presentation of a hypothesis for the mechanism of coupling of electron transport with inorganic phosphate uptake.

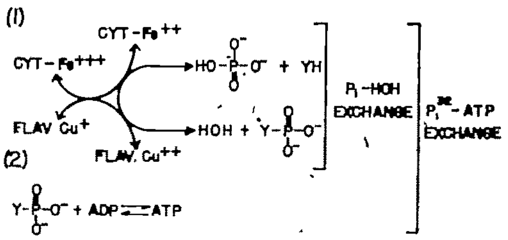
EXCHANGE REACTIONS CATALYSED BY LIVER MITOCHONDRIA IN THE ABSENCE OF ADDED SUBSTRATE

Oxygen uptake	<0·05	µM
Inorganic phosphate (phosphorus-32) – ATP exchange		
Total phosphorus-32 added	3,670	c.p.m.
Total phosphorus-32 found in ATP	820	c.p.m.
Amount of reaction, $^{32}P_i \rightleftharpoons$ ATP	14	µmoles
Inorganic phosphate – oxygen-18 exchange		
Initial atom % excess oxygen-18 in inorganic phosphate	0·278	
Final atom % excess oxygen-18 in inorganic phosphate	0·063	
Amount of reaction, $P_i - {}^{18}O \rightleftharpoons$ HOH	280	µ atoms

Each Warburg flask contained 21 µM K⁺ – ATP, 21 µM $MgSO_4$, 150 µM KCl, 150 µM sucrose, 45 µM inorganic phosphate (phosphorus-32 or oxygen-18) and washed liver mitochondria from fasted rats from 0·5 gm. fresh liver. Flasks were incubated 5 min. at 23° before addition of the inorganic phosphate-32 and measurement of oxygen uptake. Reaction time, 15 min.

Various considerations suggested that oxidative phosphorylation under suitable conditions might be a demonstrably reversible process. Prominent among these was the unexplained observation of Cohn[1] that in the presence of tissue preparations carrying out oxidative phosphorylation the oxygen of phosphate was rapidly exchanged with that of water. Subsequent experiments reported briefly herein have shown that liver mitochondria preparations in the absence of added substrate and net oxygen uptake will catalyse a rapid exchange of inorganic phosphate–^{32}P with adenosine triphosphate accompanied by a very extensive exchange of the oxygen atoms of inorganic phosphate as measured with oxygen-18. Results of a typical experiment are shown in the accompanying table. Although there was little net change in the concentrations of adenosine triphosphate and inorganic phosphate, extensive exchange had occurred and the two substances appeared to be in equilibrium. The total micromoles of inorganic phosphate which was incorporated into and released from adenosine triphosphate was calculated on the basis of the expected exponential approach to isotopic equilibrium, with the assumption that two phosphate groups of the adenosine triphosphate were available for equilibration with inorganic phosphate.

The exchange of approximately twenty atoms of phosphate oxygen for each atom of inorganic phosphate incorporated into adenosine triphosphate shows clearly that reversal of the overall reaction P_i + ADP $\rightleftharpoons$ ATP + H_2O could account for only one-twentieth of the oxygen exchange observed. The demonstration of the reversibility of the overall reaction does suggest, however, a satisfactory explanation for the observed oxygen exchange. If, as depicted in the accompanying scheme, the initial reaction or reactions of oxidative phosphorylation accompanying electron transport involve loss of an oxygen from inorganic phosphate, reversal of these



An explanation of $^{32}P_i$—ATP and P_i—HOH exchange. Overall: ADP + $^{32}P_i \rightleftharpoons$ ATP + HOH reaction(s) would lead to exchange of the inorganic phosphate oxygens with water. Inorganic phosphate under equilibrium conditions would be expected to pass through the initial reaction(s) at a rate equal to or greater than through the subsequent reaction(s). Thus exchange of inorganic phosphate oxygen could be much more extensive than exchange of inorganic phosphate with the phosphate of adenosine triphosphate.

Evidence that the phosphate oxygen exchange probably does not result from transfer of the phosphate moiety after its initial uptake comes from observations that no phosphate oxygen exchange accompanies the phosphate transfer reactions of the adenylic system which have been measured[2], and from further experiments with liver mitochondria using oxygen-18. The latter experiments have shown that when phosphate is cleaved from adenosine triphosphate by liver mitochondria in the presence of 2,4-dinitrophenol, only the expected incorporation of approximately one oxygen from water into the inorganic phosphate formed was found. When inorganic phosphate – ^{18}O was transferred to adenylic acid to give adenosine triphosphate by mitochondria oxidizing alpha-ketoglutarate, the phosphate derived from the adenosine triphosphate formed had exchanged only 1·6 atoms of oxygen per phosphate; this exchange may have resulted from some reversal of the initial step(s) of the phosphate uptake at the site of phosphorylation in the mitochondria. This is in marked contrast to the extensive oxygen exchange under apparent equilibrium conditions as shown in the table.

The exchange reactions measured with phosphorus-32 and oxygen-18 were almost completely abolished by the presence of 3×10^{-4} *M* 2,4-dinitrophenol, which gives evidence in support of the suggestion that the exchange results from a reversal of phosphorylation coupled with electron transport. The unlikely possibility that the exchange of inorganic phosphate – ^{32}P was a result of reversal of hydrolytic cleavage of adenosine triphosphate was eliminated by the finding that 'adenosine triphosphatase' prepared from mitochondria according to Kielley and Kielley[3] did not catalyse the incorporation of inorganic phosphate – ^{32}P into adenosine triphosphate under conditions similar to those used for experiments reported in the table. Thus for the exchange of inorganic phosphate and adenosine triphosphate to occur, energy derived from the cleavage of the phosphate moiety from the latter must be preserved either by reduction of a component of the respiratory chain or in the form of a 'high-energy' intermediate.

If the explanation for the marked oxygen exchange is valid, and since 2,4-dinitrophenol abolishes this exchange, it follows that 2,4-dinitrophenol either dissociates electron transport from the initial inorganic phosphate uptake or causes breakdown of a 'high-energy' intermediate before the reaction leading to uptake of inorganic phosphate. The activation of adenosine triphosphate hydrolysis by 2,4-dinitrophenol[4] would be an expected result. In the reversal of the reactions by which inorganic phosphate is incorporated into adenosine triphosphate in oxidative phosphorylation, the energy derived from the splitting of the latter would be lost in the presence of dinitrophenol and thus the formation of inorganic phosphate would be essentially irreversible.

Explanations based on experimental evidence as to how transport of electrons through the cytochrome system might be coupled with phosphate uptake have been singularly lacking. Recent fundamental studies of Taube and associates[5] may give information pertinent to biological oxidations; for example, they have found that in the oxidation of chromous ion by ferric iron catalysed by chloride ion, the activated complex contains a chloride ion as a 'bridge' between the two metallic ions. The initial oxidation product is chromic chloride, which is thermodynamically unstable and reacts with water with liberation of the chloride ion. By analogy, the hypothesis is advanced that transport of electrons from metalloflavoproteins (for example, butyryl coenzyme A dehydrogenase[6]) to a cytochrome involves participation of a 'bridge' atom between the metal of the flavoprotein and the cytochrome iron, or, similarly, between an intermediate and the iron of cytochrome oxidase. The bridge atom might be a sulphur, an oxygen of phosphate or dinitrophenol, or a group on a cytochrome. The compound formed after electron transfer would be a 'high-energy' phosphate or be cleaved by inorganic phosphate to give a 'high-energy' phosphate. Phosphate-bond energy might thus be used to reverse the direction of electron transport. The hypothesis leads to a satisfactory, but by no means the only possible, explanation of the findings reported here.

Details of these and related experiments will be given elsewhere. This work was supported by grants from the National Science Foundation and U.S. Public Health Service.

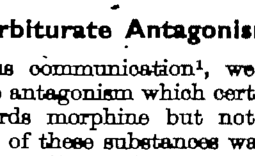
Barbiturate Antagonism

In a previous communication[1], we reported the discovery of the antagonism which certain substances exhibited towards morphine but not towards barbiturates. One of these substances was 2-4 diamino 5 phenyl thiazole. We wish to report now the discovery of a compound which is a barbiturate antagonist, and at the same time to link this antagonism with that of morphine by means of 2-4 diamino 5 phenyl thiazole (which has now been shown to be slightly antagonistic to barbiturates).

The barbiturate antagonist is ββ methyl ethyl glutarimide (designated *NP*13).



Rats and Mice. Two groups of twelve animals were taken and pentobarbitone (60 mgm./kgm.) injected intraperitoneally. To one group *NP*13 (100 mgm./

kgm.) was given by the same route. The average sleeping time of the test group was reduced to about half (a t test gave $P < 0{\cdot}1$). A similar antagonism to barbitone and phenobarbitone was demonstrated. *NP*13 (15 mgm./kgm.) itself caused convulsions which at 30 mgm./kgm. were fatal. Treatment of the animal with pentobarbitone before or after injection of *NP*13 prevented these convulsions.

Cats. These animals were aroused to a state of reflex activity and semiconsciousness from the narcosis of pentobarbital (60 mgm./kgm.). In the case of mice, rats, dogs and rabbits, *NP*13 brought about a return to consciousness from deep anæsthesia. This, however, could not be achieved with cats, and only a marked decrease in depth of anæsthesia resulted. In this respect cats behaved in the same manner as human beings (see below).

*NP*13 was effective orally, as well as by intravenous or intraperitoneal routes. It was also observed to have marked stimulating action on the barbiturate-depressed respiration, the rate being as much as doubled for a period of 5–10 min. after injection.

Rabbits. Each member of a group of six rabbits was given sufficient thiopentone (0·5 per cent) intravenously to induce a desired degree of anæsthesia. The mean duration of anæsthesia for the group was obtained. On a subsequent day the experiment was repeated, except that at the end of the thiopentone injection 3-ml. portions of a 0·6 per cent solution of *NP*13 were injected until the animal regained consciousness. The mean duration was again noted. A t test revealed a marked shortening of anæsthesia ($P < 0{\cdot}1$). Again the ability of *NP*13 to increase the barbiturate-depressed respiration was noted.

The individual dose of thiopentone to depress the respiration to 12 per minute was determined from six animals. This dose was then increased by one-third. At the end of administration of the augmented dose of thiopentone, *NP*13 was given until the animals recovered. Several days later the augmented dose alone was given; all six animals died.

*NP*13 injected alone produced convulsions which could be controlled by thiopentone.

Dogs. Six tantalum electrodes were inserted through the skull in a series of eight dogs, insulated with polyethylene and kept in position with stainless steel wire. Later, electroencephalogram records were taken. By this means it was possible to obtain a control electroencephalogram of the normal dog followed by the change in pattern as the pentobarbital took effect. Then the return towards normal produced by the intravenous injection of *NP*13 could be observed—likewise the effect of overdosage of this substance. Several experiments were carried out on each animal.

*NP*13 reversed the pentobarbital narcosis, restoring the animal to consciousness. Overdosage resulted in fasciculation, convulsions and the appearance of spikes in the electroencephalogram. The safety margin was, however, large. In none of our experiments (about twenty), despite deliberate overdosage, were there any fatalities.

We have also shown that 2-4 diamino 5 phenyl thiazole reverses the narcotic effects of pentobarbital, its action in this respect being much inferior to that of *NP*13. This substance, however, synergizes with *NP*13, the mixture giving especially greater respiratory stimulation than *NP*13 alone. Further, the convulsive effects of *NP*13 are counteracted by the thiazole.

Man. We have been fortunate in terminating the coma of some twenty cases of barbiturate poisoning with a mixture of *NP*13 and thiazole. The details of these cases will be reported fully in a clinical journal[2].

Metabolism and the Occurrence of *d*(−)Glutamic Acid in Tumour Proteins

SEVERAL investigators[1], using isotope techniques, have failed to reproduce Kögl's results on the *d*(−)glutamic acid content of tumour proteins. All such experiments were based on the hydrolysis of tumour proteins with concentrated hydrochloric acid. Kögl tried to explain the discrepancies as due to differing methods of hydrolysis[2]; but strangely enough, Kögl's feeding experiments have never been repeated. In 1940, Kögl was able to isolate, after hydrolysis, *d*(−)glutamic acid from the fæces of a dog which had been fed with Brown–Pearce tumour tissue; in 1948, he obtained in a similar way pure *d*-pyrrolidonic acid after feeding tumour protein[3] using the method of Ratner, that is, extraction of the urine with ethyl acetate at pH 2 and precipitation with barium[4]. No objections can be raised to these methods.

We have now repeated these feeding experiments employing Ratner's procedure. After feeding 1,500 gm. of human liver metastases isolated by hand to rats, 190 mgm. of pure *d*-pyrrolidonic acid was obtained in crystal form from their urine. The ethyl acetate residue, after removal of pyrrolidonic acid, yielded a dipeptide containing *d*(−)glutamic acid. Its presence and composition were shown, after coupling with dinitrofluorbenzene, by paper chromatography and infra-red spectroscopy (we are indebted to Dr. Schiedt, Max Planck Institut fur Biochemie, for measuring the infra-red spectrogram), and after hydrolysis and paper chromatography by the microbiological method of Ayengar and Roberts[5] (incubation of the material with acetone-dry powder of *E. coli* E26 (Iowa State College) test for *d*(−)glutamic acid in the presence of γ-aminobutyric acid from decarboxylated *l*(+)glutamic acid). Other feeding experiments with two human liver metastases did not yield any crystallized *d*-pyrrolidonic acid; but the micro-method mentioned above indicated clearly the presence of *d*(−)glutamic acid. After feeding rats with human liver, beef, bread or grain equal in amount to the tumour tissue used in experiments described here, we were never able to isolate pyrrolidonic acid or to detect *d*(−)glutamic acid after ethyl acetate extraction and barium precipitation following careful hydrolysis with hydrochloric acid. However, after direct careful hydrolysis of the ethyl acetate residue with 20 per cent hydrochloric acid (1 hr. on steambath) and separation over 'Amberlite

IR-4B', we were able to show by paper chromatography the presence of small amounts of $d(-)$glutamic acid which were not due to racemization.

In order to investigate whether this $d(-)$glutamic acid arose from ordinary food proteins, the urine of starved rats was analysed. $d(-)$Glutamic acid could readily be shown to be present, employing the procedures described above. The same result was obtained with human urine. We are now trying to determine differences in the $d(-)$glutamic acid content of urine from patients with different diseases.

Since we have found $d(-)$glutamic acid in the urine of starving humans and rats, it may well be that account must be taken of the presence of 'unphysiological' d-amino-acids in ordinary metabolism; this would seem to us to explain the so far ambiguous role of d-amino-acid oxidases.

Details of this work will be published in the *Zeitschrift fur Naturforschung*.

Influence of Carbon Dioxide on the Toxicity of Ammonia

RIVERS polluted with sewage effluent may contain low concentrations of dissolved oxygen at places where the concentrations of ammonia and carbon dioxide are relatively high. It is known that both ammonia and carbon dioxide are toxic to fish in high enough concentration, and that they are rendered more toxic by lowering the concentration of dissolved oxygen[1,2]. A study of the toxicity to fish of water containing both these substances when the concentration of dissolved oxygen was low, but not lethal, was thought desirable.

Sufficient ammonium chloride to give concentrations equivalent to 0, 15 and 30 parts of nitrogen per million was added to tap water at Garston, Watford. A mixture of oxygen, nitrogen and carbon dioxide was blown through the solutions to maintain the concentration of dissolved oxygen as close as possible to 4·41 p.p.m. and to give six concentrations of carbon dioxide, in the range 0–240 p.p.m. in each concentration of ammonium chloride; the temperature was maintained at 17·5° C. Ten yearling rainbow trout were placed in each of the eighteen solutions; and their periods of survival were observed. Each test was ended after 12 hr. even if some fish were still alive.

In the absence of ammonia, carbon dioxide was not toxic to the fish within 12 hr. at concentrations up to 30 p.p.m.; 60 p.p.m. carbon dioxide was toxic, however, and the periods of survival decreased as the concentration was increased above this level (Fig. 1). The solution containing ammonium chloride equivalent to 30 p.p.m. nitrogen was markedly toxic when no carbon dioxide was added; but as the concentration of carbon dioxide was increased to 30 p.p.m. the periods of survival lengthened. At concentrations of carbon dioxide between 60 and 240 p.p.m. all solutions were toxic, and there was little difference between the concentration – survival-time curve for carbon dioxide with ammonia and the curve for carbon dioxide alone. Very similar results were obtained with ammonia solutions containing 15 p.p.m. nitrogen.

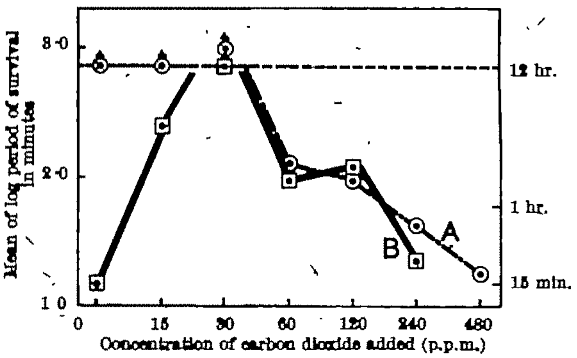

Fig. 1. Toxicity of carbon dioxide and ammonia to rainbow trout. *A*, solutions containing no ammonia. *B*, solutions containing ammonium chloride equivalent to 30 p.p.m. nitrogen

The results show that the presence of carbon dioxide up to a concentration within the range 15–60 p.p.m. reduces the toxicity of ammonia solutions; higher carbon dioxide concentrations are themselves toxic. It has been shown[1,3] that the toxicity of ammonia solutions to fish is influenced by the pH value of the water, because less of the highly toxic un-ionized ammonia and more of the much less toxic ammonium ion is present at a low pH value. The pH values determined during the experiments with ammonia solutions fell with increasing concentrations of carbon dioxide from about 7·91 when none was added to 7·4 with 30 p.p.m. carbon dioxide and to about 6·9 with 120 p.p.m. carbon dioxide. The calculated amounts of un-ionized ammonia in these solutions were 1·08, 0·26 and 0·10 p.p.m. nitrogen respectively. It is virtually certain, therefore, that the lowering of the pH value is a principal, if not the only, cause of the reduction of the toxicity of the ammonia solutions by the addition of carbon dioxide.

Ergothioneine in the Equine Ampullar Secretion

A STRIKING feature of semen and of the reproductive organs in mammals is the diversity in chemical composition and secretory function encountered among different species[1]. Recent studies on the occurrence of ergothioneine provide a good example of this behaviour. This sulphur-containing nitrogenous base, which has been isolated in a crystalline state from the boar vesicular secretion[2] and which has been shown to be capable of protecting spermatozoa against the spermicidal action of sulphydryl-binding substances[2], is present in large quantities in the semen of the boar but not in the semen of man, bull, ram or rabbit.

It has been assumed that the rather specific occurrence of ergothioneine in boar semen is linked with the protective (reducing) property of ergothioneine, which may be of particular value to boar spermatozoa in view of the following factors which distinguish the semen of boar from that of most other species: (i) an exceptionally large volume of ejaculate (up to 500 ml.), (ii) low sperm density (less than 100,000 sperm/µl.), (iii) a protracted period of ejaculation (lasting several minutes or even longer), and (iv) a very low level of seminal fructose (a few mgm. per cent). In so far as these four characteristics are concerned, there is some similarity between the boar and another domestic animal, namely, the stallion. Whereas, however, in the boar the bulk of the seminal plasma is produced by the seminal vesicles and bulbo-urethral glands, in the stallion, and also in the jackass, an important contribution is made by the very large ampullæ of the vasa deferentia, which form two well-developed organs, about 20 cm. long and 2 cm. wide. These organs, which have been studied largely by anatomists and histologists[4], have now been found to secrete large quantities of ergothioneine.

In the secretory fluid collected from the ampullæ of stallions, ergothioneine was found to occur in quantities ranging from 14·5 to 115 mgm. per cent, as against 6 mgm. per cent in the vesicular secretion. An even higher content, 63–167 mgm. per cent, has been observed in the ampullar secretion of the jackass, again in contrast to much smaller quantities in the vesicular secretion. These values have been obtained by the use of Hunter's quantitative method, based on the diazo reaction[5]. Additional evidence for the identity of ergothioneine was obtained through chromatographic analysis[3] as well as by the determination of the bromine-labile sulphur[6].

Apart from establishing yet another source of ergothioneine in Nature, the results described here provide fresh evidence that in two different animal species a given chemical constituent of semen need not necessarily arise from the same reproductive gland; thus, in the pig, ergothioneine is found exclusively in the seminal vesicles; but in the horse and ass, much more ergothioneine is produced by the ampullæ than by the seminal vesicles. Once more, it is shown by biochemical methods that anatomically analogous reproductive organs may differ substantially in their specific secretory function.

Detoxification of Diphtheria Toxin with Formaldehyde mixed with an Amino-Acid

In the preparation of diphtheria vaccine, the commonly used method involves treatment of the crude toxin with formaldehyde followed by purification of the toxoid by usually rather laborious methods, for example, precipitation at the isoelectric point with methanol in the cold.

Purification of the toxin before treatment with formaldehyde can be achieved by a relatively simple process. Thus, fractionated salting out with ammonium sulphate yields products of high purity (about 2,000 Lf./mgm. nitrogen). However, the detoxification of the purified toxin raises new difficulties, as the appropriate amount of formaldehyde has to be accurately determined in pilot experiments in order that excessive denaturation and loss of antigenicity may be avoided.

These difficulties can be overcome in the following way. Formaldehyde combines with some amino-acids in a reversible reaction, the equilibrium for some acids being highly in favour of the complex[1]. A mixture of formaldehyde and such an amino-acid will consequently have a low and almost constant concentration of free formaldehyde. Provided that diphtheria toxin reacts only with free formaldehyde but not with the amino-acid – formaldehyde complex, it should be possible to use a relatively large excess of formaldehyde, most of which will be reversibly bound to the amino-acid, and yet to keep the rate of detoxification at such a low level that complete destruction of toxicity may be secured even at 35° C. without appreciable loss of activity (that is, Lf./ml.). Furthermore, in a controlled system of this type reproducible results with different batches of toxin might be more easily obtained. An amino-acid combining with formaldehyde in an irreversible reaction cannot be used. In this investigation glycine (amino acetic acid) has been employed throughout.

Purification of the toxin. Crude diphtheria toxin, obtained by cultivation of the *PW*8 Toronto strain of *Corynebacterium diphtheriae* in Mueller and Miller's medium, was concentrated to one-tenth of the original volume by ultrafiltration. Ammonium sulphate (720 gm. per litre toxin) was added and the *p*H adjusted to 7 with sodium hydroxide. After 15 hr. at room temperature, the precipitate was separated by filtration and dissolved in water. (The filtrate was discarded.) A neutral saturated solution of ammonium sulphate was added to one-third saturation, and the precipitate formed separated by centrifugation. It was then dissolved in water, and again precipitated at one-third saturation of ammonium sulphate. After 15 hr. at room temperature, the precipitate was removed by centrifugation and discarded. The supernatants were pooled and neutral saturated solution of ammonium sulphate was added to 55 per cent saturation. After 15 hr. at room temperature the supernatant was decanted and the precipitate separated by centrifugation. The precipitate was dissolved in water and dialysed against tap water.

The degree of purity of the toxins obtained by this method was 1,800–2,000 Lf./mgm. nitrogen, the yield being 60–80 per cent of the original activity.

Detoxification. 200 ml. 0·5 *M* glycine, 3·5 ml. 40 per cent formaldehyde and 640 ml. water were mixed and the *p*H adjusted to 7 with sodium hydroxide. 156 ml. diphtheria toxin, containing 3,210 Lf./ml.

and having a purity of 2,050 Lf./mgm. nitrogen, were added and the *p*H adjusted to 7·2–7·4. The final concentrations of formaldehyde and glycine were thus 0·05 *M* and 0·1 *M* respectively, the concentration of toxin being 500 Lf./ml. The mixture was kept at room temperature for four days and then at 35° C. for twenty-five days. The *p*H was checked daily during the first week and adjusted when necessary. After twenty-five days at 35° C. the preparation was non-toxic, the activity being 480 Lf./ml. (that is, 4 per cent loss). The flocculation time was twice that of the purified toxin.

For control a mixture of the same composition but without glycine was kept at room temperature for four days and then at 35° C. After four days at 35° C., the activity was completely destroyed.

The toxoid was precipitated with sodium trichloroacetate at *p*H 4·2 [2], dissolved in water, dialysed, sterilized by filtration and adsorbed on aluminium phosphate.

Antigenicity. Half a human dose (that is, 25 Lf.) was injected subcutaneously into guinea pigs of 500 gm. weight. The animals were bled after four weeks. A pool of sera from seven animals contained 2·8 A.U./ml.

This experiment indicates that diphtheria toxin reacts only with free formaldehyde but not with the amino-acid – formaldehyde complex. The antigenic activity of the toxoid obtained was in excess of standard requirements.

Bacterial Antagonism by *Serratia marcescens*

Arising out of class-work associated with the separation of mixed cultures of *Serratia marcescens* and *Staphylococcus aureus* (*M. pyogenes* v. *aureus*), an inhibitory effect of the *Serratia marcescens* on the *Staph. aureus* has been observed.

The antibiotic responsible differs from that described by Fuller and Horton[1] in several respects. For example, its presence has not been demonstrated in shallow broth cultures of either the usual peptone–'Lemco'–broth or the medium used by Fuller and Horton. Again, using a streak-plate method o peptone–'Lemco'–agar, we have been able to shov that the inhibiting zone is a maximum after tw days incubation at 30° or five days incubation a 22° (Fig. 1).

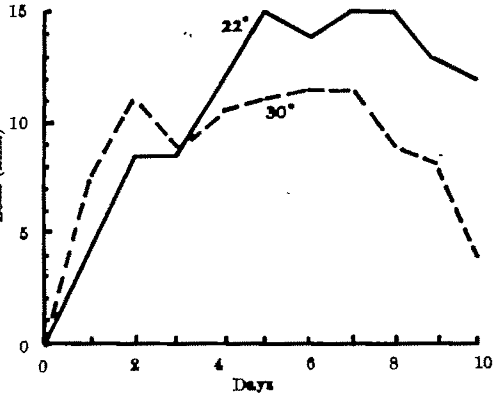

Fig 1 Inhibition of *Staphylococcus aureus* by *Serratia marcescens*

Organisms sensitive to this antibiotic include *Bacillus megatherium*, *B. subtilis*, *B. mycoides* *Corynebacterium hoagii*, *Mycobacterium phlei*, *Micrococcus flavus*, *M. roseus*, *M. viscosus*, *Staph. aureus* *Staph. albus*, *Sarcina lutea*, *Streptococcus lactis* an *Str. faecalis*.

Organisms insensitive to the antibiotic actio included *Alcaligenes faecalis*, *A. viscosus*, *Aerobacte aerogenes*, *Klebsiella pneumoniae*, *Escherichia coli*, *Pseudomonas fluorescens*, *Micrococcus tetragenus* and *Streptococcus cremoris*.

Owing to the lack of suitable facilities, it is not proposed to carry the work any further in these laboratories. The strain of *Serratia marcescens* is, however, available to anyone interested in following up the work.

Progesterone in Human Blood and Tissues

The problem as to whether progesterone is present in human peripheral blood, and in what concentrations, has not yet been solved satisfactorily.

Investigations on the content of progesterone in human blood, made with bioassay methods, have yielded contradictory results. Findings obtained by different methods showed enormous differences of concentration. Hoffmann and von Lám[1] found a maximum of 0·004 γ per c.c. of blood in the luteal phase and a maximum of 0·009 γ per c.c. of blood in pregnancy. Forbes[2] found much higher levels, up to 5·2 γ per c.c. of plasma in the luteal phase and up to 2 γ per c.c. of plasma in pregnancy. On the other hand, hitherto no progesterone has been isolated from peripheral animal[3] or human[4] blood by chemical methods. This led to the conclusion that biological tests are probably lacking in specificity, so that they react upon other substances as well as progesterone.

Considering the great importance of progesterone in the therapy of endocrine disturbances, the solution of this problem seemed indispensable. The development of very sensitive micro-methods permitted an approach to the problem of chemical measurement of progesterone from the experimental side[5,6].

Our method consists of the following steps[6]: extraction of the progesterone and partition in different solvents, isolation by paper chromatography and quantitative determination by ultra-violet spectrophotometric means; definitive identification of these final products with colour-tests, ultra-violet spectra with sulphuric acid and infra-red absorption spectrum. By this method we estimate a maximal loss of 20 per cent. The smallest amount of progesterone which can be detected is 0·05 γ per c.c. blood.

The elimination of the pregnanediol complex has been considered as an indirect criterion of the amount of progesterone produced in the organism. For this reason we considered that the best time for finding progesterone in the blood would be at the time of highest pregnanediol complex elimination. Therefore, we examined the blood of healthy women from the sixth month of pregnancy onwards. Blood samples of less than 50 c.c. were taken from the cubital vein.

The quantities of progesterone found in these blood samples corresponded approximately to the minima detectable by our method of evaluation. Therefore, the yields from several samples were collected and purified once more by paper chromatography. The ultra-violet absorption spectra in a methanol solution and in sulphuric acid showed the characteristic maxima.

The definitive identification of 61 γ of final products obtained by forty-six single extractions and purified by repeated chromatographies was made by the infra-red absorption spectrum after the method of Schiedt and Restle[7]. The infra-red spectrum showed all the characteristic bands of authentic progesterone. This proves that progesterone is contained in the peripheral blood during the second half of pregnancy.

At this time the average concentration of progesterone in plasma is 0·142 γ per c.c.; converting this value to the corresponding quantity of blood, 0·078 γ per c.c. blood is obtained.

In nine collected extracts made up of four to ten single portions each, a minimum of 0·039 γ per c.c. plasma and a maximum of 0·268 γ per c.c. plasma were found. In the corresponding quantities of blood this represents 0·020–0·151 γ per c.c. blood.

No significant variations of the progesterone concentration in blood were found during the second half of pregnancy.

In order to ascertain the speed of elimination of progesterone from human blood, the variations of progesterone concentration after an intravenous injection of 200 mgm. of progesterone dissolved in a solvent consisting of 40 per cent ethyl-urethane and 40 per cent ethyl-urea were investigated. In menopausal or ovariectomized women, we found 2·540 γ per c.c. plasma at 3–5 min. after injection. This corresponds to 1·443 γ per c.c. blood. Two hours after the injection, progesterone, in a concentration of 0·197 γ per c.c. plasma (0·116 γ per c.c. blood), could still be found. Twenty-four hours after injection, progesterone could no longer be found by our method.

In further studies the organs in which progesterone is produced were examined in order to find out how much free progesterone was present in them. Placentas, corpora lutea, corpus luteum cysts and follicle cysts were studied. All organs were examined *in toto*. The results are summed up in Table 1.

A high concentration of progesterone was detected in a mature Graafian follicle immediately before ovulation. We found 49·4 γ progesterone in 6 gm. follicle fluid with a part of the follicle wall of a twenty-eight year old woman, 14 days after menstruation.

Table 1

Materials examined *in toto*	Contents of progesterone (in γ)
Placenta, pregnancy mens. II–III	61·9
Placenta, pregnancy mens. II–III	51·6
Corpus luteum, pregnancy mens. II	56·1
Corpus luteum, pregnancy mens. II–III	33·5
Corpus luteum, pregnancy mens. II–III	26·3
Corpus luteum cyst (containing 16 c.c. of cystic fluid), pregnancy mens. II–III	21·1
Corpus luteum cyst, pregnancy mens. II–III	17·4
Corpus luteum cyst (containing 7 c.c. of cystic fluid), pregnancy mens. II	17·0
Cystic fluid contained in three follicle cysts from cystic ovary (7·6 c.c.)	7·42
Cystic fluid contained in ovarian cysts from eight women (containing 3·5–265 c.c.)	—

These investigations are being continued, in the hope of determining exactly the amount of progesterone contained in the organs where it is produced, as well as in the blood vessels leading to these organs or issuing from them. The aim is to gain a definite knowledge of the amount of progesterone present during the menstrual cycle and in pregnancy.

I am grateful to Dr. U. Schiedt, Max Planck Institut für Biochemie, Tübingen, for the infra-red absorption spectra, and to Ciba A.G. for the generous supply of progesterone for intravenous injection. This work was supported by a grant from the Deutsche Forschungsgemeinschaft.

Determination of the Origin of Opium by means of the Composition of the Ash

METHODS of determining the source of opium samples are urgently required as an aid in tightening control measures and suppressing illegal production in those areas of the world where the illicit traffic in opium originates. The Economic and Social Council of the United Nations in 1948–49 authorized research into devising chemical methods of identifying opium, and invited member Governments to participate in such a programme.

Under this programme, work was undertaken in Canada in 1949 on the composition of opium ash. A preliminary spectrographic survey of minor constituents of fifty-seven samples by Lucas and Burgener with statistical evaluation by Dunnet (unpublished results) gave promising results. It was found that, even though opium is produced from one species *Papaver somniferum*, the composition of the ash varies significantly, depending on the geographical origin of the samples.

To extend this work, and to develop the criteria for the identification of unknown samples, the ash of more than a hundred opiums from Yugoslavia, Turkey (two regions), Iran, India, Indo-China, Korea and China has now been analysed for both major and minor constituents. The elements determined were potassium, calcium, phosphorus, sodium, magnesium, silicon, iron, aluminium, titanium, boron, manganese, molybdenum, lead, tin and copper by spectrographic, colorimetric and flame photometric procedures. As an example of the type of composition variation encountered, the distribution of the potassium percentage in the ash plotted against the calcium percentage is shown in Fig. 1.

The results show that, in general, Indian samples have a high potassium and low calcium content in the ash; the druggist type of Turkish opium has a high calcium and a low potassium content, with most other samples being intermediate. The Far Eastern samples have a high phosphorus content relative to the sum of the cations. Within the Far Eastern group the northern sources (China and Korea) produce opiums with a low calcium content and often a low potassium content, while the South-East Asian samples contain more calcium. All Iranian opium ashes studied contain a relatively large amount of tin and copper which, presumably, are introduced during the handling of the raw opium. This feature is very characteristic of Iranian opium. The ash of Turkish soft opium may closely resemble the ash of Yugoslavian and Indian opiums, but can usually be distinguished by the very low silicon and iron content. Yugoslavian opium ash may contain about the same amount of potassium and calcium as some Indian samples; but the percentage of phosphorus is lower. The amounts of the trace metals, boron, manganese and molybdenum, found in opium also vary and may add corroborative evidence to aid in establishing the origin. The criteria for identification have not yet been extended to other opium-producing areas of the world, since insufficient samples of known origin have been available from these areas for developmental work.

Twenty 'unknown' samples of opium were supplied by the United Nations Secretariat for an experiment designed to test the accuracy of the criteria for discrimination of origin based on the ash composition. The origins of these samples were known to the Secretariat but not to us. In the case of several of these samples positive identification could not be made, and two possible origins were quoted in a report to the Secretariat. However, in every case where a single choice was given the origin identified was correct, and in cases where two possibilities were given, one of these two was correct.

The variation in ash composition of opium probably depends on the varieties within the species *Papaver somniferum*, and on such local features as soil, climatic conditions and agricultural techniques. In the case of Iran, the processing of the raw opium has probably contributed to the variation.

The application of the inherent variations in opium ash to the determination of the origin of the raw opium illustrates the usefulness of this techniqu and its possible application in similar problems o identification.

A full report on this work will be publishe elsewhere.

Test for the Pseudomycorrhizal Group of Soil Fungi

A CONVENIENT method has been employed fo differentiating between mycelia belonging to the so-called pseudomycorrhizal group, that is, forms o *Rhizoctonia* and *Mycelium radicis atrovirens*, and mycelia regarded as 'trivial' soil fungi which, so far have not been observed to infect the roots of forest trees.

Cones of filter-paper, cotton-wool and similar cellulosic materials are placed in Erlenmeyer flasks in such a way that they are constantly moistened by capillary rise from the nutrient solution contained in the flasks in which they stand. *Rhizoctonia* and *M. r. atrovirens*, the most common causes of pseudomycorrhizal infection in Great Britain, grow well on these cones, gradually covering them with a dense layer of mycelium. After three to four weeks growth, the cellulose material shows invasion by the mycelium at points where lesions occur in the fibres. Some of the hyphæ penetrating into the lumen of the fibres form large black sclerotia within the central canal, the zones of infection being easily recognized under the low power of the microscope as black, swollen areas. A number of hyphæ, however, traversing through the lumen do not produce sclerotia. After frequent cell divisions, they can be observed to form numerous irregular fusions giving rise to a well-defined structure (Fig. 1) very similar to that of an intercellular net present in pseudomycorrhizal associations of living root tissues. In contrast to the areas affected by sclerotia, the zones exhibiting net structure are of the same diameter as the uninfected parts of the fibres. It would appear that, in these cultural sets, the lumen of the fibres serves as a substitute for the intercellular spaces of the cortical tissues of the tree root.

We have in progress analyses of the factors inducing net formation under these artificial conditions. They indicate that the 'net' infection is mainly dependent on the constitution of the nutrients supplied and the rate of absorption of liquid by the cellulosic material. Beer wort proved to be a most suitable nutrient medium while, for example, potato-dextrose was not successful. Among the cellulosic

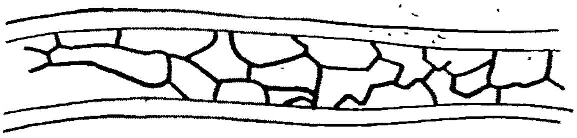

Fig. 1. *Mycelium radicis atrovirens* hyphae forming a 'net' structure in the lumen of a cotton fibre; drawing by Abbé camera (× 600)

materials employed, cotton fibres were observed to be a good substrate; acetylated cotton cellulose, however, did not encourage net formation.

None of the large number of 'trivial' soil fungi ested, for example, *Alternaria*, *Stemphylium*, *Pullularia*, *Chaetomium*, etc., although growing vigorously on the surface of the cones, has been observed o produce a net structure within the fibres. Neither was net formation recorded for true mycorrhiza-formers grown under the cultural conditions described.

Use of Ultra-violet Fluorescent Substances for Observations on Dispersal of *Phytophthora palmivora* Sporangia

Observations have been continued on the take-off of *Phytophthora palmivora* sporangia from cacao (*Theobroma cacao*) pods affected by this fungus. The technique of using 'Vaselmed' disks of 'Cellophane' (3 mm. diameter) mounted on pins above the surface of an infected pod has already been described and the take-off of sporangia thereby demonstrated[1].

No information was available as to the number of stray sporangia in the air around a pod. Therefore, the need arose for a method of distinguishing between the sporangia from a particular pod and those which might be merely constituents of what Gregory has referred to[2] as the air 'spora'.

The marking of sporangia was discussed with Dr. A. B. Hadaway, Colonial Insecticide Research Unit, who suggested the possibility of applying a substance such as salicyl aldazine, which fluoresces in ultra-violet light, as a means of recognizing sporangia from a particular source. Tests were started in which a saturated solution of salicyl aldazine in water was sprayed on to the sporangia-bearing surface of an affected pod in the field. Disks were then placed above the pod as already described. The disks were afterwards examined under the microscope with an illumination source rich in ultra-violet light. Preliminary attempts were unproductive, apparently because salicyl aldazine is insufficiently soluble to give an adequate deposit on the sporangia *in situ*. It seemed desirable to use a more soluble substance in order to obtain a greater concentration on the sporangia. However, before the use of salicyl aldazine was abandoned, this substance was applied to sporangia in the dry form, using a small hand bellows. Later, when the disks were examined, a few sporangia were found with particles of salicyl aldazine adhering. This procedure suffered from the disadvantage of introducing an extremely artificial condition, in that the take-off and dispersal of a sporangium would be affected in an unknown way by the accompanying particle. In seeking a suitable soluble substance for use in these studies, I am greatly indebted to Mr. J. A. Radley, Industrial Research and Development Laboratories, Reading, who suggested and supplied samples of three substances (primuline *A*.150 (I.C.I.) (C.I. No. 812); rhodamine 6 *GDN* 500 (I.C.I.); stilbene derivative) for trial in Nigeria. In the course of preliminary but not exhaustive tests, it was decided that primuline *A*.150 would be the most suitable of the three substances supplied. It was used exclusively in further experiments and is later referred to here as primuline, for the sake of brevity. This substance is soluble in water (5 per cent by weight at 30° C.) and gives a greenish-yellow fluorescence. When a saturated solution was sprayed on to sporangia *in situ*, they were readily stained by the primuline and became very conspicuous in ultra-violet light. Incidental observations indicated that primuline did not exert any toxic effect.

Sporangia showing the characteristic primuline fluorescence have been observed on disks exposed in rainless periods when take-off apparently occurred in 'dry' air. The number of sporangia per disk has averaged 0·3 per 12-hr. period. Larger numbers of sporangia (average 1·4 per disk per 12-hr. period) were observed on disks exposed during periods when rain fell, suggesting that rain-splash take-off had occurred. It has already been suggested that sporangia are commonly dispersed in splash-droplets[1]. Non-fluorescent sporangia were observed on some of the disks examined; these sporangia may have come from the air 'spora'; but it is also possible that they may have been sporangia from the primuline-treated pod which had escaped treatment.

The procedure used for these observations on dispersal of *Phytophthora palmivora* by marking sporangia with primuline has served satisfactorily to confirm the phenomenon of take-off in 'dry' air. It is possible that this technique can be usefully applied to similar studies with other fungi. Detailed results will be published elsewhere.

This communication is published with the permission of the Inspector-General of Agriculture, Nigeria. I am indebted to Imperial Chemical Industries, Dyestuffs Division, for information on the solubility and fluorescence of primuline *A*.150.

Somatic Selection in Fungi

In a recent communication, Calpouzos[1] reported that prolonged selection of sporulating material from recent single or mass spore isolates of the fungus *Cercospora musae* gradually increased the intensity and uniformity of sporulation in later cultures even though the spores selected were always of asexual origin. He suggested that if the original isolates had been heterokaryotic this observation was in agreement with the gradual sorting out, by selection, of a nuclear type having a greater spore-producing potential. Although this is a possibility in the case reported by Calpouzos, a similar situation has been encountered in my own experiments under conditions where heterokaryosis is ruled out as a possible explanation.

A normal culture of *Aspergillus nidulans* has both asexual conidia (which are always uninucleate) and sexual ascospores. Transfers may be made by conidia, ascospores or hyphal tips. In the course of routine maintenance it was noted that after a few transfers by single conidia the formation of perithecia became progressively delayed and infrequent; until after the fourteenth transfer no perithecia were produced. Since this fourteenth transfer the line has remained asexual for more than a year. After the fifth and ninth conidial transfers, however, single ascospores were used for starting new cultures. In these sub-lines germination of ascospores was initially poor; but after several generations of transfer by ascospores, germination and perithecial formation improved until the lost characteristics of the normal culture had been regained.

A series of transfers by single ascospores for the ascosporal line, made in parallel with the conidial transfers, led to a marked decrease of asexual spores. From the third and ninth generations of this line, sub-cultures were repeatedly transferred by single conidia, and the sub-lines also regained the normal balance of sexual and asexual spores. Thus a change occurred in these two lines in the direction of the method of propagation (sexual or asexual) used, and it was reversible by reversal of the method of propagation. In the asexual line the gradual change reached its extreme in an irreversible change to an *imperfect* form.

An observation probably related to that in *Aspergillus* was made on homokaryons derived from recently isolated heterokaryons of *Penicillium cyclopium*[1], which is known only in the asexual form. In this case colonies arising from single uninucleate conidia varied in their sporulation, the more fertile arising disproportionately often from spores formed early in the life of the parent mycelium. Transfer by hyphal tips or sterile aerial mycelium appeared to lead to a delay in sporulation if not to a real decrease in the number of spores. On the other hand, parallel cultures obtained by continuous transfer through single conidia resulted in a gradual increase in the intensity of sporulation. The changes were found to be reversible whenever tested.

In a preliminary investigation into the inheritance of the difference in *A. nidulans* an autonomous yellow spore mutation was introduced into the ascospore selected line with sparse conidia, and a heterokaryotic association formed between this marked line and the conidial-selected line[2]. The newly formed heterokaryons sporulated freely, giving both green and yellow conidia. They also gave a normal number of perithecia, some of which originated from the mating of two nuclei from the sexual type parent (being recognized by their giving progeny all with yellow conidia), some from the fusion between nuclei from the sexual and from the asexual type parent (which gave mixed progenies with yellow and green conidia), but some also from the fusion of two nuclei from the asexual type parent (which gave only progeny with green conidia). All spores, whether green or yellow, sexual or asexual, gave mycelia with a normal ratio of conidia and perithecia. Thus, not only are the nuclei of the asexual type parent capable of giving the full range of development in the cytoplasm of the heterokaryon but they are still capable of doing so following their extraction from the heterokaryon by means of asexual conidia. We can only conclude therefore, that the difference between the two selection lines is extranuclear in origin.

Since in fungi all cells, capable of reproducing at all, can form complete organisms and in doing so generally give identical results, the differentiation between ascogenous hyphæ, conidiophores and vegetative mycelia must be due not to the nucleus but to the condition of the cytoplasm in the differentiating region. The normal nucleus is capable of determining and responding to the full range of differentiating cytoplasm so that a full range of organs is produced; but mutated nuclei are known which fail to give this full range, as, for example, where non-sporulating forms are produced (Pontecorvo and Gemmell[4], Sansome[5], Hansen and Snyder[6]). That the differences in *A. nidulans* considered above are not of this nuclear kind is shown by the ability of a nucleus originally of a non-sexual type to give the full range of development when present in the cytoplasm of the heterokaryon. The failure of differentiation must reside in the cytoplasm. Now cytoplasmic differences can arise from chance irregularity in distribution of self-reproducing bodies, or from environmental changes or from nuclear action. In higher organisms, nuclear genes play the predominant part in differentiation by their orderly control of cytoplasmic change. In the present case to relate the progressive and reversible changes in spore frequencies to nuclear differences would be to imply a progressive and reversible rate of mutation of a very unlikely kind. It is much more likely that in both species the changes were due to changes in the cytoplasm that perhaps spring from non-random distribution of its components. This could arise by differential multiplication under environmental stimulus (relatable perhaps to staling of the medium) or as a normal outcome of differentiation. Irrespective of the origin of these cytoplasmic differences, as a result of the selection practised here, they have been progressively built up until larger, more permanent differences such as distinguish tissues in higher organisms have been attained. It would seem that one difference between fungi and most higher organisms lies in the less effective co-ordination of cytoplasmic changes, that is, the less rigid control of the cytoplasm by the nucleus in the fungus. Even so it would appear that cytoplasmic differences can be built up and broken down by somatic selection in rotifers[7] and *Lemna*[8]; so that the control of the fungus is related to changes in higher organisms. The information to be gained from the fungus would thus appear to be of potential value to our understanding of the process of differentiation in general.

I am indebted to Prof. K. Mather and Mr. L. G. Wigan for helpful discussion in the preparation of this report.

Prolonged Stimulation of Wool Growth following Injections of Ox Growth Hormone

DURING an investigation of the pituitary regulation of wool growth, various ox anterior pituitary preparations were injected into normal sheep. The sheep were individually fed a constant weighed ration, and wool growth was measured by clipping an area of 20 cm. × 20 cm. defined by tattoo lines on the midside of the body at weekly or fortnightly intervals. The wool samples were extracted to remove ether-soluble and water-soluble grease, and the oven-dry weight taken as a measure of wool growth over the period between two successive clippings.

In the first experiment, four ewes (two Romney Marsh and two Suffolk) were each injected with 4 ml., daily for fourteen days, of an alkaline saline extract of ox anterior pituitary glands (*F.G.S.* 289) prepared as described by Young[1] and Reid[2]. Four ewes (two of each breed) were maintained as controls. Wool growth was measured over two preliminary periods of fourteen days each prior to commencing injections. Wool growth thereafter was expressed as a percentage of the corresponding mean value for the preliminary period. During the first week of injections, wool growth in the treated group was significantly ($P < 0{\cdot}01$) increased by 17 per cent above that of the controls. A reverse effect was seen during the second week of injections, the wool growth of the treated group being 14 per cent below that of the controls. This effect was not significant, one of the control sheep being sick during the week and showing a depression of wool growth. The value for this sheep was omitted from the comparison. After the cessation of injections, wool growth of the treated sheep significantly ($P < 0{\cdot}05$) increased relative to the controls, the difference reaching nearly 30 per cent fourteen weeks after the cessation of injections, and gradually disappearing over the next ten weeks. There was no significant difference between the two breeds in their responses to treatment. The pituitary extract used was rich in growth hormone but also contained prolactin, thyrotrophic hormone and luteinizing hormone in good amounts.

In another experiment with ewes of the same breeds, four ewes were injected daily with 5 mgm. of ox growth hormone (24 *GH*) for five weeks. The effect on wool growth is shown in Fig. 1. Wool growth in treated ewes of both breeds increased relative to the controls throughout the period of injections ($P < 0{\cdot}01$) and continued above the control-level for twenty-nine weeks after the cessation of injections ($P < 0{\cdot}01$) when the experiment was terminated. The stimulation of wool growth was greater in the Suffolk than in the Romney Marsh ewes both during and after the injection period.

When similar experiments were carried out with Lincoln ewes, a stimulation of wool growth was observed during the period of injections of both anterior pituitary extract and growth hormone; but the response disappeared soon after the cessation of injections except in three ewes (two out of twelve ewes injected with anterior pituitary extract, and one out of eight injected with ox growth hormone). One cannot be sure, of course, that their individual responses were, in fact, due to the treatment.

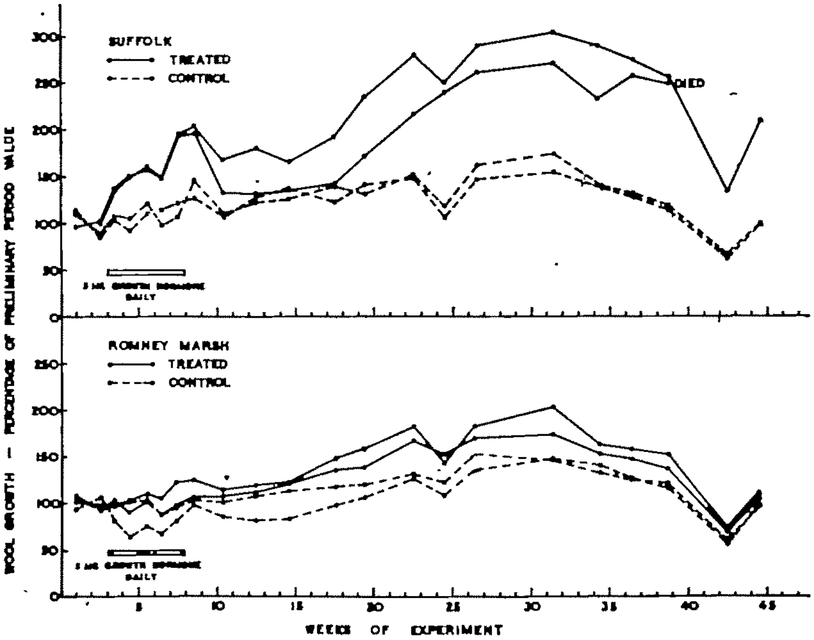

Fig. 1

It was postulated that the prolonged responses of wool growth recorded with the Romney Marsh and Suffolk ewes were due to an immune-type reaction resulting in an increase in the secretion of growth hormone by the sheep's own pituitary or a decrease in its rate of destruction. The sera of the injected sheep were accordingly tested for antibodies to ox growth hormone by the tannic acid hæmagglutination reaction[3]. The results of these tests have been described elsewhere[4]. Antibodies to ox growth hormone were detected in the sera of sheep showing prolonged responses of wool growth. The titre was not correlated with the size of the wool response, but too few observations were available to estimate the correlation with accuracy. More work is in progress to test the hypothesis further.

I am indebted to Dr. E. Reid for his collaboration in the preparation of the pituitary extracts used in the above experiments.

FORTHCOMING EVENTS

Wednesday, September 1st—Wednesday, September 8th

British Association for the Advancement of Science (at Oxford).—Annual Meeting.

Wednesday, September 1

At 8.30 p.m.—Dr. E. D. Adrian, O.M., F.R.S.: "Science and Human Nature" (Presidential Address).

Thursday, September 2

At 10 a.m.—Sir John Cockcroft, F.R.S.: "Recent Developments in Nuclear Physics" (Presidential Address, Section A).

At 10 a.m.—Sir John Lennard-Jones, F.R.S.: "New Ideas in Chemistry" (Presidential Address, Section B).

At 10 a.m.—Sir Gavin R. de Beer, F.R.S.: "Archaeopteryx and Evolution" (Presidential Address, Section D).

At 10 a.m.—Prof. W. H. Pearsall, F.R.S.: "Growth and Production" (Presidential Address, Section K).

At 11.45 a.m.—Prof. L. S. Hearnshaw: "Recent Studies in the Psychology of Thinking" (Presidential Address, Section J).

At 2.30 p.m.—Dr. C. B. Williams, F.R.S.: "Phenology—The Study of the Seasons" (Presidential Address, Section X).

Friday, September 3

At 10 a.m.—Prof. E. A. G. Robinson: "The Changing Structure of the British Economy" (Presidential Address, Section F).

At 10 a.m.—Dr. Willis Jackson, F.R.S.: "The Effect of New Materials on Engineering Progress" (Presidential Address, Section G).

At 10 a.m.—Sir Mortimer Wheeler: "Colonial Archaeology" (Presidential Address, Section H).

At 10 a.m.—Mr. Ronald Gould: "The Teacher in the Twentieth Century" (Presidential Address, Section L).

At 10 a.m.—Dr. R. E. Slade: "Agriculture—The Industry and the Science" (Presidential Address, Section M).

At 11.30 a.m.—Prof. J. A. Steers: "The Coast and the Geographer" (Presidential Address, Section E).

At 8 p.m.—Prof. W. E. Le Gros Clark, F.R.S.: "Reason and Fallacy in the Study of Fossil Man".

Sunday, September 5

At 8 p.m.—Prof. C. A. Coulson, F.R.S.: "Science and Religion".

Monday, September 6

At 10 a.m.—Dr. C. J. Stubblefield, F.R.S.: "The Relationship of Palaeontology to Stratigraphy" (Presidential Address, Section C).

At 10 a.m.—Prof. A. D. Macdonald: "The Relief of Pain" (Presidential Address, Section I).

At 8 p.m.—Dr. F. P. Bowden, F.R.S.: "Friction".

APPOINTMENTS VACANT

Applications are invited for the following appointments on or before the dates mentioned:

Assistant Advisory Officer (with an honours degree in agriculture or pure science, and a special interest in grassland work) in Agricultural Botany—The Secretary, Edinburgh and East of Scotland College of Agriculture, 13 George Square, Edinburgh 8 (September 4).

Assistant, Grade A (with graduate or equivalent qualifications), at Sheffield College of Commerce and Technology, to teach physics in National Certificate Courses in Chemistry and Metallurgy, in advanced level classes for the general certificate of education, and in various City and Guilds courses—The Director of Education, P.O Box 67, Leopold Street, Sheffield (September 4)

Assistant Lecturer in Metallurgy—The Registrar, The University, Manchester 13 (September 11).

Chemists (with a first- or second-class honours degree or equivalent in chemistry, and with research experience, preferably in physical chemistry), with the Ministry of Supply at various research stations mainly in the south of England—The Ministry of Labour and National Service, Technical and Scientific Register (K), 26 King Street, London, S.W.1, quoting F.546/54A (September 11).

Research Demonstrator in Geography—The Registrar, The University, Sheffield (September 11).

Research Officer (with an honours degree in engineering or science or equivalent qualifications) in the Division of Building Research, Commonwealth Scientific and Industrial Research Organization, Highett, Victoria, to participate in a programme of theoretical and experimental research on the properties and uses of lightweight concrete and gypsum plaster as structural materials—The Chief Scientific Liaison Officer, Australian Scientific Liaison Office, Africa House, Kingsway, London, W.C.2, quoting 390/209 (September 18).

Senior Research Officer or Research Officer (with a university degree in veterinary science, with postgraduate research experience in the control of animal diseases or equivalent qualifications) at the Animal Health Research Laboratory, Commonwealth Scientific and Industrial Research Organization, Parkville, Victoria, to undertake the general responsibilities of a veterinary pathologist and bacteriologist in laboratory and field investigations, and to develop an individual interest in one of the research projects—The Chief Scientific Liaison Officer, Australian Scientific Liaison Office, Africa House, Kingsway, London, W.C.2, quoting 201/81 (September 18).

Lecturer in the Department of Organic Chemistry—The Registrar, The University, Liverpool (September 20).

Lecturer (graduate, with qualifications and/or experience in measurements and/or heavy electrical engineering) in Electrical Engineering—The Registrar, The University, Manchester 13 (September 22).

Lecturer in Dressing of Minerals and Coal Preparation—The Registrar, The University, Leeds 2 (September 27).

Lecturer or Assistant Lecturer (with an honours degree in physical oceanography, mathematics or physics, and prepared to spend several weeks each year at sea) in the Department of Oceanography—The Registrar, The University, Liverpool (September 30).

Chemist or Metallurgist (with a first- or second-class honour degree or equivalent in chemistry or metallurgy, and with post graduate research experience, particularly concerning the study of corrosion), with the Ministry of Supply, Port Harcourt, Nigeria, to study the effects of tropical conditions on Service materials and equipment—The Ministry of Labour and National Service, Technical and Scientific Register (K), 26 King Street, London, S.W.1, quoting F564/54A.

Physicist (with a first- or second-class honours degree in physics and considerable experience of instrumentation research and development) in the Rocket Propulsion Department, Ministry of Supply Westcott, Bucks, to lead a small section on rocket instrumentation research—The Ministry of Labour and National Service, Technical and Scientific Register (K), 26 King Street, London, S.W.1, quoting 285/54A

Research Assistant in the field of Physical Chemistry (reaction kinetics)—The Secretary, University College, Exeter.

Scientific Assistant (with a degree in agriculture or natural science, a knowledge of languages, and ability to write clear concise abstracts in English), for duties which will mainly consist of examining and abstracting world scientific literature on grassland and field-crop research—The Director, Commonwealth Bureau of Pastures and Field Crops, Hurley, near Maidenhead, Berks.

Scientific Officer (with a first- or second-class honours degree in chemistry or equivalent qualifications, and a sound theoretical knowledge of inorganic and physical chemistry, and experience of modern methods of inorganic analysis), at the Capenhurst Works of the United Kingdom Atomic Energy Authority, near Chester, to carry out research and development work on analytical methods—United Kingdom Atomic Energy Authority, Industrial Group Headquarters, P.O. Box 19, Risley, Warrington, quoting 650

Scientific Officer (with a first- or second-class honours degree in physics with subsidiary mathematics, and preferably with some knowledge of electronics), at Fort Halstead, Kent, for experimental small-scale work on fundamental problems in connexion with the study of phenomena associated with explosions—The Senior Recruitment Officer, Atomic Weapons Research Establishment, Aldermaston, Berks, quoting 209/WGH/2.

Scientific Officers (with a first- or second-class honours degree in engineering, physics or mathematics or equivalent qualifications) in the Department of Scientific and Industrial Research, Mechanical Engineering Research Laboratory, East Kilbride, Glasgow, for research in several branches of mechanical engineering, for example, fluid mechanics, heat transfer, lubrication and improvement of mechanisms—The Ministry of Labour and National Service, Technical and Scientific Register (K), 26 King Street, London, S.W.1, quoting C 551/54A.

Senior Technician in the Department of Botany—The Secretary, Bedford College (University of London), Regent's Park, London, N.W.1.

REPORTS and other PUBLICATIONS

(not included in the monthly Books Supplement)

Great Britain and Ireland

Department of Scientific and Industrial Research. Summary of Progress of the Geological Survey of Great Britain and the Museum of Practical Geology, for the year 1953, with Report of the Geological Survey Board and Report of the Director. Pp. iv+90. United States Naval Observatory. Circular No. 51: Positions, Areas and Counts of Sunspots, March–April, 1954. By Dr. Winifred Sawtell Cameron. Pp. 4. (Washington, D.C.: U.S. Naval Observatory, 1954.) [57

SOCIAL RESPONSIBILITY IN THE MODERN WORLD

RECENT presidential addresses to the British Association have frequently considered the impact of science on society—generally an aspect of hat impact which the president could discuss with pecial authority—and have sought to indicate to he layman some implications of the advance in knowledge and technique for the world to-day. That esponsibility is frankly accepted by this year's president. Dr. E. D. Adrian, whose address is printed on p. 433, believes that the Association should show he layman where the scientific age is leading him and that the success of the Association's meetings is o be judged by its impact on public opinion.

The theme of Dr. Adrian's address, however, is not so much the impact of science on society, as its impact on man himself. To appreciate the difference it is unnecessary to look back so far as Dr. Adrian himself did, to the famous meeting of 1860 which, as he pointed out, emphasized both that man himself is part of the physical world and also man's determination to go on searching for truth—a determination which has been sternly challenged even in the West during the past twenty years. We need look no further than the meeting at Oxford just sixty years ago. At that meeting, at which, in his presidential address, the Marquis of Salisbury referred particularly to our ignorance of the nature of atomic structure, of the ether, and of the causes and origins of life, Sir Oliver Lodge gave the first public demonstration of wireless signalling by means of electromagnetic waves, and Lord Rayleigh and Prof. William Ramsay gave a preliminary account of a new gaseous constituent of the atmosphere. The isolation of argon and helium and the other rare gases still lay in the future, with Becquerel's discovery of radioactivity. Even when next the Association met at Oxford in 1926, although Rutherford had indicated the possibility of atomic fission at a price, the discovery of the neutron lay half a dozen years ahead. Atomic physics and radiochemistry were still to develop, and even broadcasting was a relative novelty which had yet to exert its full power over the mind and habits of society.

On any comparison of the impact of scientific discovery and its applications on society between the meetings of the Association at Oxford in 1894 and 1926, and between that of 1926 and the present, the changes in habit, in opportunities for good and for ill have been far more profound in the second period. As Dr. Adrian pointed out, in atomic physics we face discoveries which could be used to devastate half the world, and if so applied would at least make life in the other half extremely precarious. Moreover, the direct effects of atomic explosions, though of chief concern to the strategist, are not the only dangers: repeated atomic explosions might lead to a degree of general radioactivity which no one can tolerate or escape. The dangers of contamination associated with the supply of atomic energy for industrial use can be avoided by suitable precautions; but in a major war such precautions would soon be set aside, if indeed they could be organized effectively. Dr. Adrian is almost certainly right in suggesting that a long war between powers well armed with atomic bombs would involve an order of radioactive contamination which neither victors nor vanquished could escape.

This additional risk of catastrophe does not, he argued, make our predicament much worse than that of earlier generations. Our predicament is the inevitable result of our curiosity and of the physical nature of the world in which we live; but if we can make our behaviour worthy of our increased knowledge, we can live safely. In other words, scientific advance has imposed on man the need for standards of conduct and forms of social organization which are appropriate for the new powers which are put into man's hands and the changed conditions under which he has to live. If man is to use wisely and safely the immense powers now at his command, he must accept the discipline that such use demands and adapt himself and his institutions accordingly.

Advances in atomic physics are not the only advances in science which make such demands on man. Advances in medical science can be misapplied, and drugs can be used for subduing men's minds as well as for the relief of pain and the cure of disease. Prof. A. V. Hill two years ago pointed to some of the implications of the eradication of disease in the way of social discipline for the backward areas of the world; and, as Dr. Adrian reminds his audience this year, a drug or a system of education which would make us all do as we are told, a method of producing radical conversion to a new system of belief or a knowledge of new ways of rousing patriotic ardour, could all be used with consequences as grim as the genetical deterioration in a radioactive world. The psychiatrist who discovers a cure for paranoia may find he has also revealed a convenient way of producing it.

How precarious is the division between the beneficial and harmful effects of any particular discovery has been emphasized by Mr. Charles Morgan and other modern novelists; and it cannot be too firmly insisted that if we continue to tolerate war, there is no kind of scientific investigation which might not be used for making war more destructive, no discovery in the field of human conduct which could be guaranteed harmless. The alternative to social discipline is, in fact, the renunciation of the whole process of discovery and investigation. To rely on increased knowledge for defence as well as attack is more likely to postpone than avert catastrophe, and the core of Dr. Adrian's address lies in his plea for the individual and social readjustment which these grave possibilities demand as a condition of the continuance of civilization.

The scientist, said Dr. Adrian, has a dual responsibility. He must apply his science to learn as much as possible about the mental and physical causes of our behaviour, and he must study human nature to prevent its failures. He cannot, however, wait; for the discoveries might make us act more wisely. He must take men and women as they are, and make it his task at meetings like those of the British Association to point out that the human race cannot survive more than a few thousand large atomic explosions whether they hit or miss their targets.

If the British Association could make this known universally, Dr. Adrian believes it would have justified its existence, and to do so may just come within its declared purposes: "to give a stronger and more systematic direction of inquiry" or "to obtain a more general attention to the objects of science and a removal of any disadvantages of a public kind which impede its progress". He is less confident that a fuller understanding of the physiology of the brain or use of the means at our disposal to ensure clear heads or even tempers after a period of strain or fatigue would assist materially our efforts to live peacefully. Such means may diminish friction and misunderstanding, but we must find out what human behaviour is like before we try to explain how it is produced; and Dr. Adrian's address is an impressive plea for the many branches of social science to provide a dispassionate study of what actually happens in our society. In our pattern of human behaviour the units are men and women, rather than cells or molecules, on one hand, or on the other hand the large groups, with which it is often far easier to deal. When all allowance is made for the differences between the units, the general principles which determine their behaviour should stand out the more clearly because we are dealing with millions and not only individuals. With the increased knowledge psychologists now possess of the irrational factors which can sway the smaller groups as well as the family and the individual, Dr. Adrian believes the stage is set for what might well be the most important scientific development of this century.

Scientists and laymen alike may be growing more aware of the value of social investigation and of the degree of certainty it could bring; but they are scarcely as yet convinced that the kind of observation that the social scientist can make is really objective and precise. Few are ready, as Dr. Adrian remarks, to believe that the social scientists are more open-minded than themselves, and that they are capable of the open-mindedness and an almost superhuman power of selection which the nature of their material demands—of seeing the wood as well as the trees in it. Recognition of the difficulty of controlled experiments encourages reluctance to act on the findings of social scientists even when we can see that there are facts to be ascertained about our relations to one another, our usefulness in society and about the risks we take, and that the search for these facts could be conducted on reasonably scientific lines.

While therefore the social scientist deserves more generous support and a fitting place in the full stream of academic life, we should not expect too much. We may well find out a great deal about the tensions which lead to war without seeing how to eliminate war. Nevertheless, biological studies warrant the suggestion that human beings are not to be thought of as incapable of improvement. Alone in the animal kingdom, we possess a nervous system which enables us to order our ideas in words, and a way of thought which allows us to compare a new problem with an old; and our increasing background of experience makes Dr. Adrian confident that we are constantly acquiring new habits and new ways of thought. Our brains must have been so modified by what we have learnt that they are physically and chemically different, and better adapted for the complex social life of our time. We have more knowledge at our disposal, and if all goes well with our training, our brains should be more civilized than those of our fathers, and those of the next generation more civilized than ours.

It may well be that the scientific investigation of mankind can help the process of civilization by determining the weak points in our equipment and suggesting remedies; though such scientific activities may play only a limited part in the development of human society in this scientific age. The power we have acquired over the forces of Nature may indeed permit us to increase our mental training as well as our standard of comfort; but it does not follow that in many parts of the world the university, as we know it, will play the part in civilizing the most intelligent citizens that Dr. Adrian predicts. The university could not, admittedly, have opened its doors and extended its influence without the very inventions that have been blamed for our troubles—cheap printing and improved means of communication and transport. Whether the university is to be a fully effective civilizing influence depends on two factors: the threat to intellectual freedom, and our sense of social responsibility and self-discipline.

The control over Nature which science has given us has enabled us to improve our natures by more education in the arts of civilized living, and we may be able to do so more rapidly if we extend our insight into human behaviour and if we know where we are going. But we can no longer take it for granted that the British Association and other bodies will be able to foster this and every type of inquiry. Although it is human nature to inquire, to learn by experience, and to profit by what it finds out, that instinct, that right of inquiry, is threatened to an extent unknown since the Association was founded. Not only in Germany, in Italy, in Japan, in the U.S.S.R., in China, but even in the United States, man's right to knowledge and freedom of investigation have been challenged to an extent which made, for example, Columbia University centre its bicentennial celebrations around the theme "Man's Right of Knowledge and the Free Use thereof".

That threat cannot safely be disregarded while we seek to foster investigations which may indicate more precisely exactly how such anti-scientific forces arise and just how it is the values and ethics of science and of scholarship generally come to be repudiated. By and large, mankind knows why those values and that ethic are sometimes repudiated. It is not fresh knowledge that will enable mankind to restore generally the conditions in which creative work flourishes, and solutions for the problems of mankind are sought with uninhibited, vigorous and imaginative minds: it is moral courage to act with wisdom and responsibility on what we already know.

No survey of the horizons which man's mind has yet to explore, and no plea for freedom of investigation and for clear unhampered communication of ideas, is adequate which takes no account of this need for wisdom and responsibility. "We have," said Sir Charles Sherrington, in his Gifford Lectures on 'Man on His Nature" (p. 404; Cambridge University Press, 1940), "because human, an inalienable prerogative of responsibility which we cannot devolve, no, not as once was thought, even upon the stars. We can share it only with each other." Dr. Adrian mentions such social responsibility; but he does not drive home the real sharpness of the threat in anti-scientific and cultural trends to-day, or the challenge to individual as well as to social responsibility.

Every generation of mankind has to re-make its culture and its values and to re-adapt its institutions to the demands of changing circumstances and in the light of new knowledge; the tempo of change in our generation is such that our intellectual, social and political processes increasingly fail to keep abreast of contemporary needs. Hence there are strains and difficulties not only for institutions and the body politic, but also for the individual. It is in part, of course, a problem of communication, of assisting the individuals who make up the mass of society to understand what is happening under the impact of science, of integrating scientific thought and tradition into the rest of the general culture of our time. Only by so doing can we prepare men and women for the discipline demanded in an age of atomic power, broadcasting, television, aviation and the new powers of controlling disease, and leave them no longer bewildered by natural forces they do not comprehend, victims of ignorance, superstition and fear.

We can accordingly only draw comfort from the belief that new techniques and the growth of higher education will make successive generations more civilized if scientists address themselves seriously both to the task of exposition and interpretation, and to that of studying the limitations of our existing intellectual tools and frames of thought and their adequacy for the relations and conditions of to-day. As Dr. P. W. Bridgman has pointed out, we have to examine such social concepts as human rights, duties and responsibilities in the light of the environment with which technological change has surrounded them, and to revise if need be the conceptual foundation of our social and political system in the light of such an examination. In particular, we must have regard to the imperfection with which social organization functions in large communities, where the individual is liable to lose the sense of community and responsibility, and where what were virtues in a small community may even be inverted.

Dr. Bridgman may well be right to suggest that any such appraisal will result in a society in which relations between the individual and society rest on virtues comparatively unfamiliar. What is even more important, however, is that the process of human improvement which he and Dr. Adrian visualize does not rest solely on the furtherance of scientific inquiry into problems of human or civil biology, the physiology of the brain, human behaviour and social, industrial or economic relations. It rests equally on the co-operation and understanding of the ordinary citizen—on the sharing with him of the responsibility of which Sherrington spoke—and working out with him the changes and adaptations required to avert the grave dangers to which mankind is exposed and strengthen the control which at present we exert. Whether the future is regarded with pessimism or with optimism, however, depends less on the ability of men and women to adapt themselves to new circumstances or on the number of those trained to cope scientifically with their environment, than on the capacity of men and women to exercise the self-discipline demanded. It also depends on the wisdom and imagination which informs their political and social decisions, and on the emergence of standards of conduct, ideals, traditions and values and a view of life no less noble than those that inspired our forefathers and enabled them to hand on to us so rich a cultural and spiritual heritage, in which science itself is one of the great human endeavours and experiences.

THOMAS JEFFERSON, UNITED STATES PRESIDENT AND FARMER

Thomas Jefferson's Farm Book, with Commentary and Relevant Extracts from Other Writings

Edited by Edwin Morris Betts. (Memoirs of the American Philosophical Society, Volume 35.) Pp. xxiii + 178 + 552 + 8 plates. (Published for the American Philosophical Society.) (Princeton, N.J.: Princeton University Press; London: Oxford University Press, 1953.) 15 dollars; 120s. net.

It is a remarkable fact that two of the great founders of the United States were not only busy statesmen but also large farmers deeply interested in improving their land and in raising the standards of their own and their neighbours' agriculture. It is gratifying to us in these islands to recall that it was to Britain that they looked for the models on which to work, and which they were able to modify successfully to suit their local conditions. British students of agricultural history are familiar with the volume of letters written by George Washington to Arthur Young giving an account of his husbandry at Mount Vernon, Virginia, as well as more general information about the rural economy of other parts of the country: this was published in 1801, two years after his death. The American Philosophical Society has now given us a facsimile of the "Farm Book" of Thomas Jefferson, who lived at Monticello, near Charlottesville, Virginia, about 125 miles south-west from Washington, D.C., and who, like other Virginians of the time, increased his estates until finally they extended to some ten thousand acres. Much of his property was woodland; but several hundred acres were cleared and farmed:

the operations covered a wide range, for the estate had to be nearly self-supporting, providing not only most of the food but also clothes and shoes for the work-people and their families, nails for the carpenters, and other necessities.

Thomas Jefferson was born in 1743, was educated at the College of William and Mary, Williamsburg, and began life as a lawyer; at the age of twenty-six he entered public life, continuing therein for some forty years. His father died while he was still a boy, leaving him five thousand acres; another five thousand came to him later from his wife's father, but he had to leave them in the hands of managers who were not particularly competent. On his return from France "a ten years abandonment of them to the ravages of overseers", he wrote in 1789, "has brought on them a degree of degradation far beyond what I expected". Only in intervals of his active public life—the longest was from 1793 to 1796—and after his retirement from the second term of his Presidency in 1809, did he have time for close supervision on his own land.

The "Farm Book" covers the period 1774–1826. It is more of a note-book than a systematic diary; but the editor, Mr. E. M. Betts, of the University of Virginia, has included a number of Jefferson's letters which throw a flood of light on the problems of estate management of those days.

The work was done by Negro slaves, of whom he had about two hundred; as they increased by birth any superfluous ones were sold: the sale of a man for £100, the purchase of a woman and two sons for £210 and the transfer of eleven for £550 are among the entries. They seem to have been well fed and well looked after; in principle, Jefferson favoured abolition; in practice, he recognized its impossibility. For their food they were provided with maize meal, wheat flour (which they preferred), pork (600 lb. a year for a man and his wife), molasses, fish and peas. The molasses had to be purchased, but keen watchfulness was necessary as considerable quantities of water were liable to be added in transit.

The cash crops were tobacco and wheat; for home consumption large quantities of maize were needed. In the early days, Jefferson's farm manager had concentrated on maize and tobacco, growing them in a two-year rotation. Little manure was used, and inevitably the productiveness of the soil suffered heavily. Following Washington, he recognized the need for a rotation of crops, including clover, on the Norfolk lines, and among others he tried a five-course: peas, wheat, maize, wheat, clover. He used farmyard manure and also gypsum, about which he became enthusiastic. Much of his animal manure was lost, however, because of forest grazing; to obviate this he designed "a moveable air cowshed, to be set up in the middle of the field which is to be dunged, and soil our cattle in that"—an anticipation of the modern milking bail. However, he recognized that manuring might be uneconomical: "we can buy an acre of new land cheaper than we can manure an old one", he wrote.

He began his public life in the firm belief that the country should be predominantly agricultural. Farmers were for him "the chosen people of God": persons "whose breasts he has made his peculiar deposit for substantial and genuine virtue"; indeed, the establishment and survival of democracy in his view depended on peopling the land with farmers. The workshops that supplied manufactured goods, and "the corrupt cities they bred", should remain in Europe, exporting their goods to America in exchang for tobacco. After the war with Britain, however he favoured more self-sufficiency.

He had a flair for mechanical invention, an perhaps his best contribution to agriculture was hi discovery of an exact formula for the constructio of the mould board of a plough that would cause th minimum of friction in its passage through the soil He experimented with sheep; he had many pigs—he kept a breeding sow for every two labourers—and he gives details of the amount of maize require to fatten a pig: one bushel, he said, will produc 10 lb. increase in weight: assuming the bushe weighed the usual 60 lb., the result is within abou 10 per cent of the figure given by the much late Danish experiments.

Jefferson was not only a statesman and an advanced agriculturist, he was also a man of wide education; this, however, did not save him from the fat that has at times befallen other agricultural improvers he kept open house for his visitors and was often i debt; he might have died a bankrupt but a publi subscription was raised to make his position secure

The book is sumptuously produced and is wel worthy of its distinguished subject: it is a rich stor of material for students of the agricultural history of that important period. The American Philosophical Society is to be congratulated on its enterprise in arranging for production of the book, an Mr. Betts for the prodigious labour and carefu scholarship he has devoted to its preparation.

E. John Russell

MODERN CYTOLOGY

International Review of Cytology

Edited by G. H. Bourne and J. F. Danielli. Vol. 2. Pp. xii+545. (New York: Academic Press, Inc.; London: Academic Books, Ltd., 1953.) 11 dollars.

SYMPOSIA and volumes of reviews must at one time have been intended to spare scientists the burden of reading the original literature in fields of research lying a little to one side of their own; but they have long since become a literary incubus in their own right. This stricture applies far more to those reviews which are in reality mere bibliographic inventories than to articles of the style presented here. The present volume contains more than a dozen lengthy and carefully prepared reviews by recognized workers in the fields of cytology, cytochemistry and microbiology. It is admirably got up—as indeed it should be, at the price.

First among the articles of non-sectarian interest is Hämmerling's admirably translated review of his work on *Acetabularia*—work which no biologist should admit to being ignorant of. At the other extreme, Conway's concentrated theoretical discussion of the redox pump will presumably have the smallest following, for most biologists admit, with uncalled-for complacency, to a total ignorance of thermodynamics. Between these extremes are a number of reviews of orthodox pattern: cytochemical findings are described, their validity inquired into, and their significance pondered upon. Gaillard's summary of a wide variety of researches into the behaviour of cells *in vitro* stands rather apart from this classification, and so does the article shared between Mudd and Sutcliffe on the cytology of bacterial cells. Both contain evidence that is not so compendiously presented elsewhere.

In limited space, only one of the several articles that deserves it can be called specially to the attention of specialists in other fields: that in which H. R. Mahler writes on those complex many-stage enzymic reactions which remain functionally in gear in cell-free extracts containing mitochondria and smaller particles. The *kind* of system that gives functional coherence to the metabolic activities of the cytoplasm is slowly beginning to appear, and it seems to be particulate rather than, in the ordinary sense, 'skeletal'. Indeed, the cytoskeleton seems to have a rather ether-like status: one feels that something of the kind should be there, but more than one observation (for example, on ultracentrifugation) that could rank as an *experimentum crucis* can be reconciled to its non-existence. Now that complex reaction sequences appear to have an anatomical as well as a functional unity, it might be argued that the whole concept of 'separate' enzymes has no place inside the cell, however well it has done duty by the perhaps highly specialized and unrepresentative enzymes that are secreted by cells and work outside them. The argument is tempting, but it will not do. 'Separateness' does not stand or fall by separability, and the enzymes of complex many-stage reactions could be identified by specific inhibitors and substrate competences (or, in micro-organisms, by the skilful use of gene mutations) even if not one of them had been isolated. As it happens, many have been; but what is important about these complex reactions is not their divisibility but their actual indivision, and the biologist will be satisfied to learn of the existence of a level of integration that is so much larger than the molecule and so much smaller than the cell.

P. B. MEDAWAR

SENSORY GATEWAY TO THE MIND

The Human Senses

By Prof. Frank A. Geldard. (Wiley Publication in Psychology.) Pp. x+365. (New York: John Wiley and Sons, Inc.; London: Chapman and Hall, Ltd., 1953.) 40*s.* net.

THE study of the human senses has long been and still remains among the most rewarding fields of psychological inquiry. More than a third of Stevens's "Handbook of Experimental Psychology" is devoted to it. A book exclusively occupied with the subject is therefore to be welcomed. The present effort covers partly the same ground as Piéron's "The Sensations", the English version of which appeared in 1952, though in mastery of the subject it scarcely bears comparison with its distinguished predecessor.

The usefulness of Prof. Geldard's book lies chiefly in its careful review of the recent literature on those aspects of the subject in which he is primarily interested, and those aspects are at least as much physiological as psychological. His own publications include papers on visual phenomena, retinal fatigue and brightness contrast, and on somesthesis. He has also made an exhaustive study of the so-called vibratory sense, arriving at the conclusion that it is not a separate sense but simply 'pressure in movement'. But he is equally at home in the chapters on hearing, temperature and labyrinthine sensitivity, kinæsthesis, smell and taste, though he makes little attempt at synthesis or critical evaluation of rival theories.

Prof. Geldard has not confined himself to American sources. The omission of any reference to the researches of Piéron, doyen of sensory psychophysiology, is all the more noticeable. Nor does the chapter on "The Skin and its Simuli" leave the reader with any glimmering of the haptic qualities of the hand as studied by Révész or Katz.

At one brief stage, in the chapter on colour vision, the author decides to drop the psychophysiological approach and assume a phenomenal viewpoint. It is a pity he did not sustain this second viewpoint throughout. He might then have found it unnecessary "to sidestep the vexing problem of form perception". He might also have found it possible to give more adequate consideration to the problem of pain; no part of the book reveals the limitations of a purely psychophysiological approach more sharply than the discussion of pain. Conceivably he might also have been led to see the importance of intermodal phenomena in sense perception.

Prof. Geldard's initial manifesto raises our expectations. "The highroad to the understanding of human nature," he declares, "is by way of an appreciation of man's senses and of the fundamental role they play in the attainment of knowledge and the regulation of behaviour." This may be the case; but we shall never convince anyone that it is unless we extend our interests to the personal and social aspects of sense perception. Prof. Geldard's inclinations do not seem to reach so far. He does not seem to share the view that the psychologist's task is not to concern himself with eyes, ears and skin as such but with a person seeing, hearing, touching. His restriction of interest is scarcely calculated to lead the reader on the "highroad to the understanding of human behaviour".

JOHN COHEN

THE PRACTICE OF FORESTRY

Forestry

By Prof. H. G. Champion. (The Home University Library of Modern Knowledge, No. 226.) Pp. vi+230. (London: Oxford University Press, 1954.) 6*s.* net.

THERE has been a long-standing need for a simple survey of what is meant by forestry. It is, of course, difficult to write an outline of any large subject, and the method of approach depends partly on the background of the author. Prof. Champion spent a considerable part of his professional life in India, and he has travelled widely in other parts of the world, both tropical and temperate. He has accordingly drawn his illustrations from a wide field. This is the distinctive quality of the book, and it adds greatly to its interest.

The book is comprehensive and the reader may rest assured that he has got at least a glimpse of every facet of the subject. The first chapter deals with "Forests and Trees", and brings together varied information from all over the world: the oldest trees, the tallest trees, the greatest girths, as well as short discussions on all aspects of the life-history of trees from light requirements and pollination to mycorrhiza. This is one of the most interesting chapters in the book. The second chapter, entitled "Structure of Forests", presents the forest as a plant community, discussing not only its structure in an ecological sense, but also the effect of competition, certain aspects of succession, the classification of forests on climate, and the ecological influences of man on the forest. Again, the illustrations are drawn from a world background. Chapter 3 discusses briefly the varied products from the forest, not only timber as such and as a source of cellulose, but also bamboos, fibres, gums, resins, medicines, fodder, etc. Then follows a brief but interesting discussion of the history of forest clearance to provide agricultural land, for timber products, and for hygienic purposes, such as an anti-malarial measure and for tsetse control.

Under the title of "Forest Influences" the author outlines the effect of forests on rainfall, water regime including erosion, wind and temperature, as well as a brief reference to the forest as a habitat of animal and plant life. The chapter on "Forest Conservation and Protection" discusses fire protection, control of grazing and protection against animals, insects and fungi, as well as natural agencies such as wind. The next chapter outlines methods of surveying forest resources, methods of extraction of timber, and the preparation of products from sawn timber and pulpwood to wood distillation and resin derivatives. The next three chapters deal with sylvicultural techniques used in the natural and artificial regeneration of woods and their subsequent tending; generalities are spiced with sufficient detail to make them interesting. Under the title of "Growth of Crops", the techniques of the measurement and management of forests are discussed, while the chapter on "Reclamation and Afforestation" draws its examples from the Culbin Sands in Scotland to the papyrus swamps of Uganda. There is a short chapter on forest policy, law, research and education, while the last gives a brief picture of forestry in the United Kingdom.

In the concluding paragraph, the author considers that it is inevitable that there will be a further reduction in the area at present under forest in certain parts of the world, particularly the less developed, but that this loss will be made good, at least in part, by afforestation of land mistakenly cleared of forest and also land not previously woodland, but which can now be made to carry trees by improved techniques, as in Great Britain, and also by improved production per acre. He has no doubt as to the future of wood as a major world raw material.

This book worthily upholds the reputation of the series for serious but non-technical exposition of a subject. It is remarkable for the amount and variety of the information that the author has presented so skilfully, concisely and lucidly. H. M. STEVEN

MONKEYS AS PETS

The Monkey Book

By Ernest P. Walker. Pp. xii+154. (New York: The Macmillan Company, 1954.) 6.50 dollars.

THIS book, by the assistant director of the National Zoological Park at the Smithsonian Institution, Washington, tells the owner or would-be owner of a pet monkey all that he should know. Mr. Walker has not only successfully supervised the keeping of monkeys in captivity for many years, but also has been answering questions on the subject for as long—now he has set forth his experience and knowledge in an attractive volume. The book will be of great value not only to private keepers of pets but also to those concerned with the care of monkeys in zoos and research laboratories.

The work is divided into two parts; the first part deals with general questions of animal management as applied to the primates, and is full of valuable information ranging from feeding, cages, exercise and health to psychology, and what to do when a pet escapes. This is excellent, and the chapter entitled "Psychology", pointing out that the psychological problem of keeping pets happy is of even more importance than the problem of supplying them with food, should be studied by everyone who keeps wild animals in captivity. A sub-section of the first part giving instructions for the maintenance of cultures of mealworms, wax moths and crickets as food for captive animals is particularly helpful.

The second part of the book deals systematically with all the more-or-less valid groups of species of living primates other than man, and a page is devoted to each of the genera recognized by the author, from lemurs and lorises to anthropoid apes. An introduction gives a short explanation of classification and then a brief description is given of representative species of each genus, with notes on distribution, habits and food, and advice on management in captivity, the probability of obtaining specimens from dealers, and the range of market prices. A special feature of the book is the excellent series of illustrations, mostly from photographs but some from drawings, that gives a splendid pictorial guide to the variety of forms throughout the primates.

The author believes that no pet, if properly treated, will give more satisfaction and companionship than a monkey. The instructions for the care of pet monkeys given in this book will enable owners to derive the maximum of enjoyment from their favourites and will prevent the premature loss of many animals.

The book concludes with a well-chosen select bibliography and a full index. It is a pity that its very high price, for a book of its type and size, will put it beyond the reach of many of those pet enthusiasts outside the United States who would benefit most from possessing it.

L. HARRISON MATTHEWS

COALFIELDS OF GREAT BRITAIN

The Coalfields of Great Britain

Edited by Sir Arthur Trueman. Pp. xi+396+7 plates. (London: Edward Arnold (Publishers), Ltd., 1954.) 63s. net.

THIS book is a welcome successor, well suited to present-day requirements, of Walcott Gibson's "Coal in Great Britain", the second edition of which appeared in 1927. During the intervening period, many striking advances have been made in the study of the Carboniferous coals and associated strata with which the present book is almost exclusively concerned. More especially, mention should be made of the palaeontological results achieved by Sir Arthur Trueman and other well-known workers, and the detailed re-mapping of the coalfields by the geologists of the Geological Survey. Greater precision has been achieved in most branches of the subject, and many of its aspects have been revolutionized by discoveries of recent years, including, it may be added, those of the authors themselves. All this material, old and new, has been dealt with by Sir Arthur Trueman and his expert collaborators with commendable clarity, and also adequately. Indeed, an outstanding feature of the work is its well-balanced presentation of a subject so charged with detail as is coalfield geology. The two needs which the book aims to meet, those of the ologist and the worker in coalfield industries, have een clearly kept in view, and both interests have een served without sacrifice of scientific method or the requirements of the practical point of view. erhaps a chapter dealing with the fossils of the oal Measures and associated strata and their use as ratigraphical indicators may be fittingly singled ut for mention. For it serves as an example of eatment of a highly technical subject in a manner which the results can be appreciated and applied ike by the geologist and the mining engineer.

The chapter dealing with fossils forms one of a ries of opening chapters written by Sir Arthur rueman which comprise nearly a quarter of the olume. In these chapters, the essential points in gard to the geology of coal and the Coal Measures re described in an admirably simple and yet comrehensive way. The subject of coal as a rock is llowed by a description of the rocks of the Coal Measures. Next, geological structures are dealt with; en fossils of the Coal Measures and their use; and stly, the origin of the British coalfields.

Individual coalfields are next described in a series f eleven chapters. The main plan in each case is to pply a general introduction followed by accounts f the succession and structure, details of the stratiraphy and, finally, notes on coal reserves, references eing appended to each account. Where required by dividual writers of these chapters, additional atures are included, such as the anthracites of outh Wales, and the character of the coals in other ases; the history of development of the local ining industry; proved or possible extensions of a orked coalfield; and the occurrence of igneous ocks, especially in Scotland. Not only coal, but lso other materials of economic importance such as edded iron-ores and fireclays, are reviewed. In eneral, a variety of interests are served *pari passu* ith more important objects.

A brief statement of the authors concerned and ontents of these detailed chapters may be given. rof. L. R. Moore deals with the South Wales coaleld, and with the coalfields of the Forest of Dean, omerset and Glamorgan. The Kent coalfield and ther possible concealed coalfields south of the English Midlands are treated by Dr. C. J. Stubbleeld. The Yorkshire–Nottingham, Lancashire and orth Staffordshire coalfields are described respectvely by Mr. Wilfrid Edwards, Dr. F. M. Trotter and rof. F. Wolverson Cope; those of North Wales by rof. Alan Wood and of the South Midlands by Dr. . H. Mitchell. Accounts of the Northumberland nd Durham fields are given by Dr. W. Hopkins, nd of Cumberland (mainly Whitehaven coalfield) y Dr. Trotter. Finally, the coalfields of Scotland re described by Dr. Murray Macgregor.

The book is adequately illustrated with a number f well-drawn maps, horizontal sections and comarative vertical sections of the local successions of oal-seams, together with drawings of representative nd zonal fossils and photographs of plants. An ndex is supplied at the end of the volume. This ne work will undoubtedly be widely read and be losely scrutinized by the many workers concerned n the subject. It is one of great economic as well as cientific interest, and Sir Arthur Trueman and his o-authors are to be warmly congratulated on their chievement. In its pages a critic can find little for omment except to praise, and a reader, whether xpert or student, will gain both pleasure and nlightenment.

J. E. Richey

ORGANIC CHEMISTRY IN THE ARTS AND MANUFACTURES

Industrial and Manufacturing Chemistry

By Geoffrey Martin. Part 1: Organic. Seventh edition, revised by Edward I. Cooke. Pp. xxi+752. (Kingston Hill: Technical Press, Ltd., 1952.) 90*s*. net.

BETWEEN the first and seventh editions of this book lies a period of forty years; indeed, a thirty-year interval separates the sixth edition and the present revised seventh, and during this period many branches of industrial chemistry have been completely revolutionized, while others, unknown forty years ago, have arisen, undergone development and reached an important place in the present-day industrial field. New chemical techniques and new methods of manufacturing old-established products have followed expansion in chemical knowledge, chemical engineering advances and metallurgical developments of the past forty years. But much of this finds no record in the present book.

The present editor, Mr. E. I. Cooke, faced with the stupendous task of dealing with the twenty-four sections into which this book is divided, has succeeded with his collaborators in completely re-writing some sections, dealing respectively with petroleum refining, manufacture of condensed milk and milk powders, the fatty acids industry, fuel gas industries and coal tar. Much has been done to improve the sections dealing with sugar, rubber and synthetic drugs: a former section on explosives has been omitted and replaced by one on the plastics industry, which unfortunately had to be curtailed due to considerations of space.

But a very large part of the book bears the stamp of the original edition; in most of the sections there are no references to original literature later than 1912 and, almost throughout, the statistical information given relates to the years around 1910–12 and is thus completely valueless. Also, this defect is not remedied by the very sketchy statistical information in Appendix 3. Much of the book, in fact, can be considered as little more than a historical review of the subject-matter to the stage it had reached some forty years ago; but from this point of view there is much to recommend the volume. Yet, if it is to continue to serve a useful purpose every section of it needs drastic treatment to bring it up to date—a task likely to involve its subdivision into two if not three volumes.

Extensive developments have taken place during the past few years in methods of extracting and refining fatty oils, in continuous hydrogenation and in the manufacture of margarine, now an important article of dietary throughout the Western world, though only four pages are here allotted to its consideration. The treatment of essential oils, perfumery materials and synthetics is quite inadequate. The term 'artificial silk' went out of use many years ago, being replaced by the word 'rayon', which finds no use, however, in the present volume, though the relevant section on the cellulose industry is generally well written. Similar remarks apply to the manufacture of alcohol and industrial solvents, where considerable development has occurred during the past thirty years so that we no longer strive to get methyl alcohol and acetone in commercial quantity by wood distillation.

The major technological change in the detergent industry, no longer based exclusively on soap, has brought new products and created new difficulties. The continuous soap-making process and continuous soap drying are revolutionizing the industry, causing thereby an immense saving in labour and steam. Changes such as these should have found mention in the relevant section.

Appendixes 1 and 2 and the two indexes appear to have been well done. The book is well produced and generally free from typographical errors.

H. M. Langton

A NEW PERIODIC TABLE

A New Periodic Table of the Elements Based on the Structure of the Atom

By Dr. S. I. Tomkeieff. Pp. 30+2 charts. (London: Chapman and Hall, Ltd., 1954.) 10*s*. net.

To demonstrate the periodicity in the properties of the chemical elements, Lothar Meyer chose the most direct representation: he plotted the elements in the order of their atomic weights on the abscissa, and the values of the property in question on the ordinate. At the same time, Mendeléef published the Periodic Law in the form of tables; he had to decide whether the short or the long period were to be chosen for the length of the rows; but this was the only arbitrariness.

During the following decades innumerable attempts were made to improve on Meyer and Mendeléef. All sorts of representations, trees with branches, concentric circles, spirals, figure-eights, and various three-dimensioned curves—mostly drawn on the surface of cylinders and cones—were tried; behind all this was the hope to get nearer to the mystery of the periodic system if a more perfect arrangement could be found. But the scientific result of all these attempts was nil; an understanding of the periodic system could only be achieved on the basis of quantum mechanics.

It is somewhat astonishing to see that quite recently "A New Periodic Table of the Elements" has been published which is a revival of the old discarded attempts. The curves, for example, which represent the specific gravity of the elements, are based on one of the well-tried spirals and can, naturally, not avoid the old drawbacks: such elaborate curves are tedious to draw, provide no help to the memory, and do not contain any information which could not be included in simpler representations. How much more clearly does the periodicity of the specific gravity show up if plotted according to Lothar Meyer's straightforward method! The author recommends even a cone-shaped periodic chart, another repetition of previous suggestions; whoever takes the trouble to follow the advice to cut the drawing out and to gum it together as a cone, will scarcely get any insight into the sequence of chemical elements which the usual tables do not give.

It is not very obvious why the author calls his table "based on the Structure of the Atom". It is true that the introductory pages contain an elementary description of the shell structure of the atoms, but this text has no connexion with the graphic part of the publication. It is also doubtful if the "Table of Elements"—extending over fourteen lavishly printed pages—will be of great help to the readers. One of the columns describes the colour o the elements, necessarily with the frequent monotonous repetition of the descriptions "silvery white or "iron-grey"; this column should make it clea that the main value of the periodic system is no based on the properties of the elements as 'simpl bodies', but on the periodicity which they show i their compounds. It is also questionable if th information provided in the column "normal stat of the element" is very instructive without givin more details; we are, for example, told that normally iodine is a metal.

Being a geologist, the author may have reason t suppose that some of his colleagues will find such periodic table useful; but it is not certain tha chemists or physicists or, for that matter, geologist who have sufficient knowledge of chemical an physical publications on the periodic system, wi obtain much help from his book.

F. A. Paneth

THE STABILITY OF THE SUN

Dialogue Concerning the Two Chief World Systems—Ptolemaic and Copernican

By Galileo Galilei. Translated by Stillman Drake foreword by Albert Einstein. Pp. xxvii+496 (Berkeley and Los Angeles: University of Californi Press; London: Cambridge University Press, 1953. 75*s*. net.

Thomas Salusbury, in the address to th reader which prefaced his translation of th book now in question, wrote in 1661, ". . . tha singular and unimitable Piece of Reason and Demonstration the Systeme of Galileo. The subject of it i a new and Noble part of Astronomy, to wit th Doctrine and Hypothesis of the Mobility of the Eart and the Stability of the Sun". This is a very jus epitome of the famous *Dialogue*, in which th Ptolemaic system is held up to ridicule and th Copernican system abundantly justified. It is perhaps, strange that nothing should be said of th Tychonic system, which had been elaborated by th greatest astronomical observer of the time, but ther it is. Galileo was concerned with the Copernica system alone and did not even mention th fundamental discovery of the elliptic form of th planetary orbits, familiar as he was with Kepler' work and highly as he thought of it in general Strange!

The dialogue is between three characters, Salviat and Sagredo, friends of Galileo distinguished by nobl birth and keen intellect, and a third character denote by the name Simplicio. Both Salviati and Sagred were dead at the time when the book was written into Salviati's mouth are put the words of Galile himself, while Sagredo represents a witty and astut man versed in the general learning of his time. T him are given the most biting comments on th arguments of Simplicio, the peripatetic philosopher while Salviati-Galileo, with his tongue in his cheek remarks, for instance, "Sagredo, you are too causti and sarcastic. Let us put all joking aside, for we ar dealing with serious matters". It has been surmised that Simplicio was meant to represent Pope Urban VIII, but this is unlikely on several grounds. The Pope, Maffeo Barberini before his elevation, had bee a friend and patron of Galileo and was certainly n extreme Aristotelian, and Galileo, although n courtier, would scarcely have invited certain retribution by putting, as has been suggested, arguments supplied by the Pope into the mouth of a figure held up to ridicule. Galileo says that he has given "the good Peripatetic" the name because of his excessive affection towards the *Commentaries* which the neoplatonist Simplicius wrote on Aristotle. While it is not well to take everything that Galileo said in this book at its face value, there seems no reason why this should not be correct.

The *Dialogue*, while not equal to the *Discourses* as a record of original advance in the fundamentals of science, is of the greatest importance both for the immense effect that it had in winning support for the new scientific outlook and for its bearing on Galileo's personal history. The effectiveness of the arguments and ridicule brought to bear against the Ptolemaic system is widely acknowledged beyond the circle of those who have had recourse to the book. The way in which it shows the hold that certain of the older notions still had upon Galileo is less generally recognized—less still, probably, the actual errors which it reveals, particularly in the matters of the cause of the tides and the nature of comets, where Galileo was less correct than certain of his contemporaries. For all those interested in the great man's mind and in the conflicting currents of his period the book is of supreme significance, but hitherto the only English version has been the extremely rare one by Salusbury to which reference has been made.

This new translation, by Mr. Stillman Drake, is evidently a labour of love. In his excellent and modest preface the translator excuses his occasional departure from strict literalness by very properly saying that easy reading is the great requirement. He cites Galileo's dislike of pedantry: he might have quoted his predecessor Salusbury, who wrote "The Book being for Subject and Design intended chiefly for Gentlemen, I have bin as careless of using a studied Pedantry in my Style; as careful in contriving a pleasant and beautiful Impression". To-day the style of Salusbury's conscientious work, even if it were generally available, would offer difficulties to most readers. The present translation achieves an admirable balance, avoiding on the one hand colloquialisms that would be inappropriate in a classic of this kind and on the other hand a rigid verbal adherence to the text that would be troublesome. It is couched in a simple and straightforward English that has, nevertheless, well preserved the character of the original and is furnished with excellent notes which give the reader just what help he is likely to require, without holding him up by too frequent interruption. In spite of, or perhaps because of, their brevity these notes demonstrate how well qualified the translator is for his task.

The book further boasts a preface by Einstein which will be read with the attention that anything from his pen deserves. This is printed in German on the left-hand pages, with an English translation opposite. This translation is dictionary-literal, with occasionally a droll effect, as when we are told that "Apart from its revolutionary factual content the *Dialogue* represents a downright roguish attempt . . .". The roguish Galileo, at sixty-six years old, is an appealing picture. But such things are trifles. The book, which is beautifully produced, is to be warmly welcomed as offering scholarly and substantial evidence of the growing interest in the classics which lie at the foundations of modern science.

E. N. DA C. ANDRADE

AUTOMATIC CONTROL FOR ECONOMIC SYSTEMS

The Mechanism of Economic Systems

An Approach to the Problem of Economic Stabilisation from the Point of View of Control-System Engineering. By Prof. Arnold Tustin. Pp. xi+161. (London: William Heinemann, Ltd., 1954.) 25*s.* net.

UPON the conventionally trained economist this book will have some of the effects of the sculpture of Reg Butler or Barbara Hepworth on those who admire the statues in our streets: "I can't get to grips with it"; "I don't see the point of this extraordinary technique"; "It's all wrong".

It is, I think, easy to see how this exceedingly unusual book came to be written. Prof. Tustin is a very eminent designer of the means whereby electrical mechanisms acquire 'self-control' of essentially the same sort as that given to a steam-engine by its centrifugal governor. Struck by the misery and danger which arise from the booms and slumps of orthodox economic systems, he plans to stabilize these systems by building into their essential structure some features inspired by control-system engineering and working by exactly the same formal principles. But this is not all. The discomfort caused to mathematicians by the work of Oliver Heaviside (whose name appears in the text but is omitted from the index) has in the past dozen or fifteen years very largely been removed by the translation of his methods and results into the language of the Laplace transform, by which the description of the behaviour of any variable as a function of time can be replaced by its description as the sum of a set of exponentially growing or diminishing sinusoids (and thus in effect as a function of frequency), and calculations concerning it thus brought within reach of the compact elegance of vector algebra. It is, I think, the beauty and power of these mathematical methods, almost as much as the urgency of the economic problem and the hope of solution inspired by the wonderful success, in its own sphere, of control-system engineering, which has driven Prof. Tustin to attempt the conversion of economists to his gospel.

To effect this conversion he has first to teach them his language, for few economists are expert in harmonic analysis or even in vector algebra. This education he attempts in a sympathetic, ingenious and optimistic chapter of some sixty-six pages and thirty diagrams, which the non-mathematical reader is urged to "read, at first, straight through, in a light-hearted and optimistic spirit, so as to get the broad idea". I do not deny that such a man, if his lack of mathematics is accidental and not inborn, will have his imagination caught by many a stray gleam from this rich river of ideas and may even feel himself carried along by its urgent enthusiasm of exposition. But to expect the average student of economics to wrestle with this chapter, let alone to master it and add it to his effective equipment of mental tools, is wildly over-sanguine. It is still true that mathematical aptitude does much more for a man in physics or engineering, where it is indispensable, than it does in economics, where formal mathematical procedures are rather like a pair of skis, contributing tremendously to one's speed in special favourable conditions but elsewhere useless. In consequence, economics departments have comparatively few mathematically capable students, attracting instead people of equal mental calibre but with a bent towards philosophy or history. For that small group of professional economists who are mathematicians by nature but not by training, Prof. Tustin's Chapter 3 will be invaluable. This chapter could, I think, in spite of the imaginative efforts which have been made to meet the uninstructed reader half-way, be considerably improved in detail. We read, for example, from p. 55 onwards, the expression "modes of free motion"; but this phrase is not defined until several pages later. Such points may seem insignificant; but they can be fatal to a reader's effort to follow an argument.

The great unproved assumption, on which Prof. Tustin's whole thesis and programme rest, is that an economic system can be treated as a machine which cannot hide in the heart of its nature and being any autonomous capacity for responding differently, to-morrow, to a given situation from its response at a similar situation to-day. It is not, that is to say, essentially impossible to know what the economy will do in given circumstances, and it is not essentially impossible to know the circumstances themselves through and through so that nothing which matters is hidden from us. It may be, for all I know, that this assumption will be confirmed. No experiment could have a more overwhelming claim on the interest of all economists, or indeed of philosophers in general, than to find out if Prof. Tustin is justified.

G. L. S. Shackle

FOOD AND POPULATION

The Limits of the Earth

By Fairfield Osborn. Pp. 175. (London: Faber and Faber, Ltd., 1954.) 12*s*. 6*d*. net.

The author of "Our Plundered Planet", which succeeded in bringing to a large section of the American public some idea of the current profligate use of natural resources, now presents primarily to the same audience a broad picture of increasing population pressure on world food output. He does not attempt, as the title of the book might suggest, either a definition or a delimitation of the *oecumene* or habitable area of the globe, but passes in review, based on such statistics as are available, through the principal regions. Accepting a world population increase of 75,000 a day, he assesses their ability to meet the food needs of the increase.

Australia, New Zealand, Canada and Argentina are considered as the four main 'food surplus' countries, but where nationalism, rightly condemned industrialization and urbanization all threaten the home food supply and deprive the world of badly needed food surpluses. The Amazon is regarded with a certain cautious optimism; but tropical Africa, whatever its future line of development, can help the world position but little because the "African will take the land for his own". South Africa is regarded as the supreme example of the forces of science and technology frustrated by social and political conditions. The chapter on the United States underlines the author's insistence that the resources of the erstwhile "land of boundless resources" are in fact strictly limited.

The regional treatment is popular rather than profound, and least satisfactory is the chapter on Europe, where the economic position is naïvely over-simplified to fit some of the author's preconceived theories: thus, "when petroleum came into general use, the coal of England and Wales began to lose its high premium value. The strength of England's economic structure simultaneously began to diminish"; Holland has lost the East Indies, and Sweden is pioneering in new ways of population control untrammelled by religious dogma and therefore "contrasts in the ways of life of peoples living in close proximity could not be more vividly exemplified than by comparing the situation of Holland with that of Sweden" (p. 27).

A chapter on "Horizons and Mirages", devoted to additional resources, touches briefly on possibilities of increasing fisheries, using plankton, seaweeds and pond culture, and technical developments in agriculture such as soil conditioners and synthesis of proteins. On the other hand, certain obvious developments really within our grasp the author seems content to ignore. He appears satisfied, for example, with low American acre-yields needing three acres of improved farm land to support one person (against one acre over much of Europe) and quotes the U.S.S.R. with its far greater climatic handicaps as about the same standard in land requirements *per capita*. The stultifying effect of tariffs and other international trade barriers does not get a mention: the assumption seems to be that each political unit must support its own population from its own home food resources. A special word of praise is due to the publishers for continuing to bring current American thought before a wider public.

L. Dudley Stamp

METALLURGY OF CHROMIUM

Chromium

By Dr. A. H. Sully. (Metallurgy of the Rarer Metals No. 1.) Pp. xii+272. (London: Butterworths Scientific Publications; New York: Academic Press, Inc., 1954.) 35*s*. net.

This book is described as the first of a series on the metallurgy of "what are commonly referred to as 'rare metals'". The book is well printed and attractively illustrated, and contains much information of value to both students and research workers. It is divided into seven parts which deal with: (1) history and occurrence of chromium; (2) production of chromium ferro-alloys and pure chromium; (3) physical properties of pure chromium; (4) melting and casting, powder metallurgy and workability of chromium; (5) electroplating and properties of electrodeposits; (6) chromizing; (7) constitution and properties of chromium alloys.

The author's style is rather diffuse, and many sentences could be shortened without loss of clarity or subject-matter. In general, however, the writing is clear and easily understood, although occasional unfortunate mistakes or ambiguous sentences are to be found. Thus the statement on p. 254 is an incorrect description of the work of Raynor and Pfeil, and suggests the formation of a phase Cr,Al, which does not exist, while the first two sentences of the paragraph 4.4.6. are unfortunate. These are, however, minor faults in a book which will be read with much profit by all who are interested in chromium or its alloys. It emphasizes the difficulties of preparing the metal in a state of high purity, and also the lack of knowledge about the really pure metal. It is well established that the temperature variations of some properties, such as the electrical resistance, undergo abnormal and quite unexplained changes about room temperature, while the apparently unrelated change from brittle to ductile fracture occurs between 50° and 100° C., and is of extreme interest. The physical properties of transition metals such as chromium and their alloys are, in fact, a direct challenge to both theoretical and experimental workers, and a reading of this book will suggest many subjects for research. W. Hume-Rothery

A THEORY OF SOCIAL CHANGE

Political Systems of Highland Burma

A Study of Kachin Social Structure. By E. R. Leach. Pp. xii+324. (London: The London School of Economics and Political Science (University of London), and G. Bell and Sons, Ltd., 1954.) 35s. net.

THIS book, an account of the social structure of the Kachin–Shan population of north-east Burma, has a value quite independent of its descriptive content. To-day a very powerful and extensive school of anthropologists adopts what is known as the 'functionalist' approach. Institutions are thought of as functioning within a social structure which, itself, consists of individuals who are so connected up by social relations as to form an integrated whole. The social system is a functional unity and vice versa—the functional unit is a social system. All institutions support one another, all mutually determine one another, and the result will be the picture of a society in stable equilibrium.

Dr. E. R. Leach attacks this theory root and branch. He is interested in cultural change, and he frankly confesses that he finds no place for a theory of internal change in the functionalist approach. Why, he argues, should we suppose that equilibrium is 'normal'? Why should we even suppose that the societies hitherto pictured by functionalists as being in stable equilibrium really are so? On the contrary, there is every reason to suppose that these societies do change, that they are at any given moment in a state of flux. In fact, Dr. Leach goes on, the functionalists do not and have not described the societies as they really are. What they have produced as a true picture of these societies is, in fact, nothing but a highly intellectualized conceptual model; and the reason for this, to his mind, is that they are attempting to impart a precision into the mutual relationships of individuals in such societies which in fact does not exist.

The anthropologist is using a set of scientific, highly precise and highly abstract categories, and into these he is trying to fit the data of native life; but in fact the native himself does not express his social relationships except in a symbolic and highly inconsistent form. He expresses it, that is to say, through ritual. He expresses it through myth. These specific and concrete activities are, moreover, interpretable in many ways, and individuals manipulate them to suit their own self-interest and in particular their interest in acquiring power and authority. In this way the system of myth and ritual is ambiguous enough to permit shifts of power-structure and to legitimize such shifts of power-structure once they have occurred. Thus Dr. Leach would (I think) hold that only unless an anthropologist is prepared to take as his assumption the vagueness and inconsistency of myth and ritual can he advance an explanation of indigenous political and social change. If myth and ritual were as tidy as the functionalists' assumptions tend to make them, then there is no room for shifts of power and status within the system described. It is only when myth and ritual are regarded as being a sort of arsenal from which legitimizing authority can be extracted that a theory of indigenous change becomes possible at all.

The major part of the book is devoted to an attempt to work out this theory in terms of the Kachin–Shan population. Here again Dr. Leach is an iconoclast: he admits blandly that his own interpretation of their cultures is at variance with practically everything that has hitherto been published.

His view can be briefly put in the following way: we have here three sub-types of social structure—there is the Shan type, which is feudal and hierarchical; the Kachin *gumlao* type, which is equalitarian; and in between them, the Kachin *gumsa* type, which he maintains is in unstable equilibrium. This is a sort of cross-roads. It represents societies which are moving either from the *gumlao* to the Shan type or from the Shan type to the *gumlao* type. The *gumsa* type may move in either direction; its relations are not fixed. "I assume," he says, "that within a somewhat arbitrarily defined area—namely, the Kachin Hills Area—a social system exists. The valleys between the hills are included in this area so that Shan and Kachin are, at this level, part of a single social system. Within this major social system there are, at any given time, a number of significantly different sub-systems which are interdependent. Three such sub-systems might be typed as Shan, Kachin *gumsa*, Kachin *gumlao*. Considered simply as patterns of organisation, these sub-systems may be thought of as variations on a theme. The Kachin *gumsa* organisation modified in one direction would be indistinguishable from the Shan; modified in another direction it would be indistinguishable from Kachin *gumlao*. Viewed historically such modifications actually occur and it is legitimate to speak of Kachins becoming Shans or of Shans becoming Kachins. When therefore I, as an anthropologist, examine a particular Kachin or Shan locality I need to recognise that any such equilibrium as may appear to exist may in fact be of a very transient and unstable kind."

This thesis Dr. Leach pursues through material of great intricacy. Yet is this single example, drawn as it is from one particular area, typical of all situations? *Prima facie*, one would not think so. It is perfectly possible, and indeed highly probable, that certain communities are in fact in the state of equilibrium. On the other hand, it must be conceded that it was high time that a field anthropologist put his finger on a crucial difficulty in functionalist theory—that is, the great problems it raises in constructing theories of indigenous change. The importance of this book therefore stands independently of the truth or falsity of Dr. Leach's proof. Its major importance is as a well-deserved challenge to a dominant anthropological theory. S. E. Finer

THE RADON CONTENT OF THE ATMOSPHERE

By W. ANDERSON, PROF. W. V. MAYNEORD and R. C. TURNER

Physics Department, Institute of Cancer Research,
Royal Cancer Hospital, London

MEASUREMENTS of the radon content of the atmosphere were made so long ago as 1905 by Eve[1,2] in Montreal, in 1908 by Satterley[3] in Cambridge and Ashman[4] in Chicago. The values obtained by these workers ranged from $2 \cdot 0 \times 10^{-14}$ to $2 \cdot 0 \times 10^{-13}$ curie per litre, and the results as a whole seemed to support the original suggestion of Elster and Geitel[5] in 1903 that the radon in the atmosphere arises mainly from the soil. These workers noted that the highest level of active material in the atmosphere was found in fog conditions. It is interesting to note that these early workers sometimes discarded the values obtained from smoky atmospheres as appearing to be high or erratic. Since this early work, little seems to have been added to the subject except for isolated series of measurements[6]. The subject seemed of importance only in laboratories where bulk radium was being handled[7]. Even in the case of the Meuse Valley fog of 1930[8], no observations of radioactive content were reported, although investigations were carried out on a large number of chemical constituents of the fog. The purpose of this article is to present measurements relevant to this subject which have been made by us during the past two years.

Early in 1952, a series of measurements was made of the radon contents of various rooms and laboratories in the Physics Department of the Institute of Cancer Research, Royal Cancer Hospital, London, by drawing air samples of 10,000 litres through fine-grain Whatman filter papers by means of a vacuum cleaner fitted with an air-flow meter. The activity of the filter-paper samples, which was afterwards shown to have a half-life corresponding to radium A, B and C, was estimated in a lead castle arrangement of known geometry using a *GM4* Geiger counter and scaling system. The values deduced, assuming equilibrium, for various rooms, ranged from 2×10^{-15} curie of radon per litre upwards, depending to some extent on the past history of the particular site. Air samples taken on the roof of the building on sunny, dry days showed values of only 2×10^{-15} curie per litre, that is, fifty times less than the 10^{-13} average value found by the authors above.

Uncertainty as to the fraction of the atmospheric radium A, B and C being collected by such filter papers led to a series of measurements being made during which filter samples and whole-air samples were taken simultaneously, the latter being collected in previously evacuated flasks of known volume. The filter-paper activities measured with the Geiger system showed values only 2–3 per cent of those measured at the National Physical Laboratory on the whole-air samples. The latter measurements were made by transferring the air to a previously calibrated ion chamber and observing the ionization current when the radon had reached equilibrium with its solid decay products.

The inference at this stage appeared to be that the filter-paper method had a low collection efficiency of only 2–3 per cent, and that this might be the reason for the low values obtained. The ion chamber method of measurement seemed altogether less equivocal, and the construction was undertaken of a suitable three-litre chamber used with a Townsend balanced Lindeman electrometer. Before this equipment became available, the London 'smog' of December 1952 occurred and only the filter-paper method could be used for measurement.

The highest activity found on the filter papers on the first day of the smog proved to be equivalent to 8×10^{-13} curie of radon per litre, that is, four hundred times the clear, sunny day value of 2×10^{-15} curie per litre. If this value of 8×10^{-13} curie per litre in fact represented only 2–3 per cent of the total activity present, then the maximum activity of the smog on the first day could have been 4×10^{-11} curie per litre; but it must be remembered that the fraction of the active deposit collected under smog conditions may be much larger than in a clear atmosphere.

Using a reflectometer (and calibrations supplied by the Fuel Research Board) the blackenings of a daily series of filter-paper samples were converted into approximate weights in milligrams per cubic metre of solid matter from the air and these weights plotted against the measured activities of the samples. The resultant graph (Fig. 1) shows increasing activities with increasing weight of solid matter collected by the filter, from the lowest observed values to the highest figure of 3·8 mgm. per cubic metre found on the first day of the smog. There seems little doubt that when the solid matter in suspension consists of particles or aggregates of particles large enough to be collected by such filter papers, then the activity of the filter sample is related to the weight of solid matter collected by it. On the other hand, when the suspended particles are so small that the collection efficiency is very low, such a method could give a

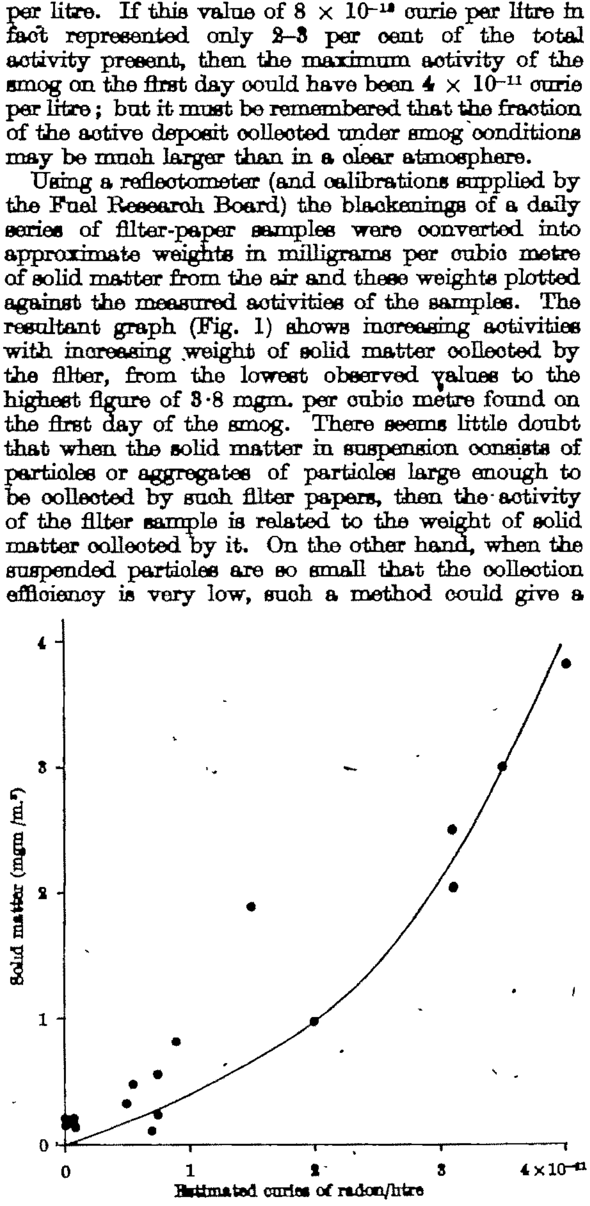

Fig. 1

low and completely misleading value for the atmospheric radon.

In May 1953, the ion-chamber apparatus became available and an extensive series of whole-air measurements was undertaken. The values obtained were greater by factors of 10–100 than those given by the filter-paper method, and the average roof value turned out to be 2–3 × 10^{-12} curie per litre, which is some twenty times that obtained early in the century by the original workers. It was suggested that these higher figures might be specific to London, and in the absence of any further smog or even fog conditions attention was turned to the possible causes of this higher radon concentration. The explanation of the relatively high radon-levels observed during fog conditions may lie partially in the retention, by the fog blanket, of radon diffusing naturally from the soil and from city structures. These conditions could reduce the dilution normally arising from mixing with higher atmospheric layers. In seeking other relevant factors, we have been led to consider the possibility that a significant fraction of atmospheric radon is derived from the burning of coal.

A few studies[9–11] have been reported in the literature on the radium content of certain coals, and values found ranging from 0·05 to 9·0 × 10^{-12} gm. radium/gm. coal ash, or 0·001 to 1·0 × 10^{-12} gm. radium/gm. coal. We have carried out preliminary estimations on six samples of coal, as supplied for domestic use, and have found values ranging from 2 to 4 × 10^{-12} gm. radium/gm. ash, or 0·05 to 0·3 × 10^{-12} gm. radium/gm. coal. The measurements were made by estimating in the ion chamber the equilibrium radon released from samples of coal ash, using modifications of both classical methods, namely, boiling off from acid solutions, or fusion with alkali carbonates[12]. Some of the samples were taken from the combined ash obtained from the burning of several kilograms of domestic coal; later, more representative samples of known origin and rank were made available. The active material was characterized unequivocally by measuring its rate of decay and also the rate of decay of the 'active deposit' remaining in the ionization chamber after replacement of the gases with aged nitrogen. Good agreement was found between values obtained by the two methods. Careful control experiments conducted on the reagents used gave negative results.

Measurements have been carried out by the fusion method on the radon content of ash, derived from coal burned in a domestic grate, at various intervals after the burning process. The results indicate that 70–80 per cent of the equilibrium radon is liberated into the atmosphere during normal burning.

We have further demonstrated that the combustion of coal gas contributes to the atmospheric radon content. Preliminary measurements on coal gas, from the normal main, introduced directly into the ionization chamber, indicated the presence of radioactivity equivalent to about 0·5 × 10^{-12} c. radon/lit. of gas. A simple method of concentrating the active material was devised in which the gas was burned with aged cylinder oxygen and the combustion gases led into the ionization chamber after removal of carbon dioxide and water vapour. In this way a five- to seven-fold concentration was achieved, and at the same time the gases were freed from undesirable tarry constituents. The activity was shown to be due to radon, using the same criteria described above. Values obtained in several tests over a few weeks ranged from 0·3 to 1 × 10^{-12} c. radon/lit. coal gas. Careful control was again exercised on the reagents and equipment employed in this work. Successive positive results of the same order of activities obtained over several weeks using the same cylinder of oxygen removed the possibility of radon contamination from this source.

The need for great care in these experiments was emphasized in earlier tests which we had conducted and in which rather higher radon values than quoted above had been found from coal gas combustion. In a control run designed to parallel the combustion experiment, carbon dioxide and nitrogen from cylinders were passed through the combustion assembly; approximately half the amount of radon found in the test run was measured in this control. It was discovered that the radon appearing in the control had been liberated from the soda-lime used for the absorption of carbon dioxide. An independent estimation placed the radium level in the soda-lime at 0·25 × 10^{-12} c./gm. Under the experimental conditions during combustion, approximately 100 gm. soda-lime were used, and were found to yield 9 × 10^{-12} c. radon (= 36 per cent total radon available). This phenomenon, unusual in that the radon is liberated under comparatively mild temperature conditions (the soda-lime is warmed to 60–80° C. by the heat of reaction), might be understood in terms of the rupture of the occluding structures caused by the chemical changes accompanying absorption of carbon dioxide. In subsequent work the soda-lime was replaced by solutions of potassium hydroxide; the control runs were then found to give negative results. It is interesting to note that the classical fusion method of radon estimation[13], which gave values generally double those obtained from the corresponding solution method, employed soda-lime tubes for removal of the carbon dioxide evolved.

It is not possible at present to assess with any accuracy what fraction of atmospheric radon may be attributed to the burning of coal and coal gas. There are wide variations with respect to time and location of the contributions from such processes, and furthermore, comparatively few figures are available on atmospheric radon-levels. The radium content of coal, and the radon content of coal gas, appear very small when considered per gram of coal or per litre of coal gas; but, on the other hand, these materials are consumed in very large quantities daily. For example, in the Greater London Area during 1953, the daily consumptions were: coal, 55,000 tons, and coal gas, 10^{10} litres. It would therefore seem desirable that further information be obtained on the significance of such contributions to total radon concentration in the atmosphere. The increased levels measured during fog conditions would find at least partial explanation if these processes are significant.

We are at present extending the scope of our measurements of the radium content of British coals and of atmospheric radioactivity at a variety of locations. The work forms part of a wider research into possible health hazards associated with prolonged exposure to small amounts of radioactive materials.

We gratefully acknowledge the help of Mr. W. J. Callow, of the National Physical Laboratory, and Dr. E. T. Wilkins, of the Fuel Research Board. We are also indebted to Sir Charles Ellis and Mr. A. M. Wandless (National Coal Board) for providing coal samples. Acknowledgments are also due to the Governors of the Royal Cancer Hospital, who supported the work by a fellowship to one of us (W. A.). Valuable technical assistance in the experimental work was given by Mr. J. G. Crookall.

NEW FACTS ABOUT COELACANTHS

By Prof. J. MILLOT

Director, Institut de Recherche Scientifique de Madagascar

THE researches upon the Coelacanths which my co-workers and I are actively pursuing, not only in the Muséum National d'Histoire naturelle at Paris and the Institut de Recherche Scientifique de Madagascar but also in the field round about the Comoro Islands, are gradually bringing into sharper focus our picture of these remarkable fishes. I have already published various papers and observations concerning them in *La Revue de Madagascar* (December 1953), in the Paris *La Nature* (April 1954), in *The Times* (June 3, 1954) and in a bulky supplement to *Le Naturaliste Malgache* (June 1954). In the present article I am able to present further new information.

From the point of view of anatomy, we are still in the initial period of descriptive studies: comparisons and interpretations, though so very tempting, would still be premature. In my article in *The Times* I have given the first indications of the arrangement of the heart and of the persistence of a vestige of a pulmonary organ. To these I am now able to add observations relating to the digestive system and kidney.

The œsophagus, remarkably wide, strongly fluted along its length and very muscular, allows the animal quite easily to swallow entire living fishes of fifteen centimetres or more, for such have been recovered intact. It is continuous with the stomach, without any anatomical differentiation: the transition from one organ to the other cannot be distinguished save under the microscope, following the transformation of the mucosa and the appearance of the characteristic long, tubular glands of the fundus present throughout the vertebrate series and already perfectly differentiated in the Coelacanths. The stomach is, like the oesophagus, very capacious, longitudinally furrowed and yellowish in colour. Its thick musculosa is exceptionally dense. Its shape is that of a V opening anteriorly and having two wide limbs of unequal length: the dorsal one, following directly upon the oesophagus, is relatively short (twenty centimetres or so) although the blunt point of the V is situated beyond the opening of the cloaca; the other limb, ventral and of more than double the length, gradually narrows and ends by a tubular pyloric portion curved into a knee-bend in the anterior part of the abdominal cavity. It opens through an annular sphincter (the pronounced differentiation of which contrasts with the total absence of a cardia) into a very short chamber, an adumbration probably of the bursa entiana or *zwischen darm* which is found more or less developed in many fishes. This, devoid of any appendage or cæcum, is in the Coelacanths no more than the antechamber to a sub-fusiform spiral intestine *en rouleau* showing nearly a score of concentric turns.

This spiral intestine, in one form or another characteristic of primitive fishes, is directly followed by the hind-gut (coprodæum), in which may be distinguished (*a*) a sub-horizontal rectum which rises in its terminal portion at the level of the vent to bend at a right-angle towards this, and (*b*) a cloacal pouch directed almost vertically downwards and the inner posterior wall of which bears a urino-genital papilla and receives besides the secretion of a median and unpaired nodular gland which is bound to it. The latter, of serous type, surrounded by a tough capsule and the size of a large hazel-nut, is of very dense texture and exceptionally firm consistency; it is probably homologous with the digitiform gland of Selachians, although of very different structure. The inner walls of the rectum and cloaca are thin and distensible, but reinforced by longitudinal muscle bands.

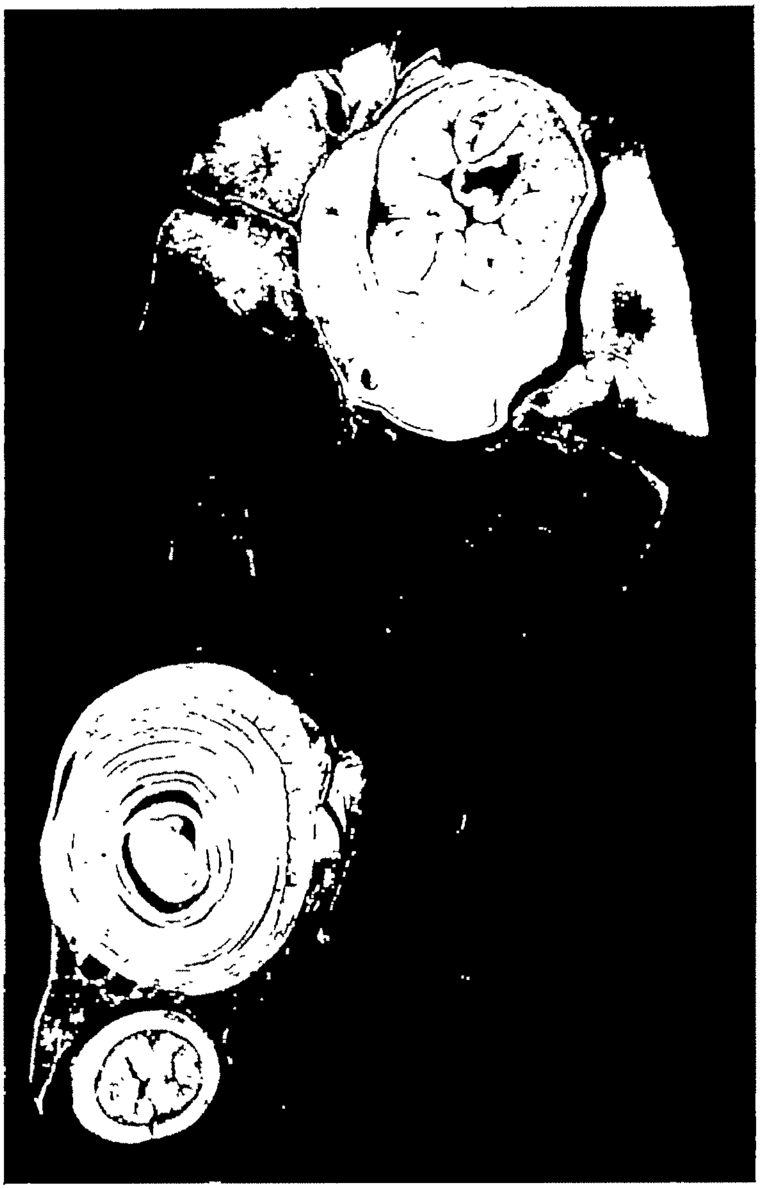
The liver, the pale slate colour of which varies appreciably from one specimen to another, comprises two lobes: the right occupies two-thirds of the length of the visceral mass; the left is a little broader but only about half as long. The hepatic cells are rich in fatty inclusions, but not specialized more or less exclusively for the storage of fat reserves as is the case with many sharks. The gall-bladder, partially buried in the bridge of connecting tissue which unites the anterior ends of the lobes of the liver, is relatively voluminous; by tapping that of specimen C^3 I was able to extract 50 c.c. of bile.

The pancreas, also well developed, forms a long yellow band, in section triangular, in structure partly fatty, occupying on the right side of the visceral mass all the depression situated between the ventral branch of the gastric V, the spiral intestine and the rectum.

The kidneys are fused together into a single median organ the position of which is unusual: it is in fact applied to the ventral wall of the abdominal cavity, behind the cloacal opening, although the testes are situated in the middle of the dorsal part of the visceral mass and therefore entirely pre-cloacal. There are two symmetrical ureters the free portions of which are quite short and expand dorsally each into a voluminous ear-shaped bladder. The bladder is thus in Coelacanths a paired formation, though the kidney is unpaired—an uncommon arrangement. The urethras approach symmetrically toward the sides of the urino-genital papilla before opening into it.

The kidney is provided with large pine-cone-shaped glomeruli and with well-developed Malpighian tubules. Its structure, markedly different from that of other fish kidneys which I have had occasion to examine, is of the highest interest; but it is complicated and requires prolonged and intricate study. Eosinophile secretions have been observed in certain tubules, as well as cavities lined with ciliated epithelium, which are probably nephridial but the disposition of which I have not yet been able to work out. Unlike that of many Teleosteans, the kidney does not contain any lymphoidal tissue, but shows considerable infiltrations of pseudo-eosinophile leucocytes. The extreme abundance of these leucocytes, their intense and diffuse hæmapoiesis, the more or less penetrating sheaths which they form around the greater part of the abdominal organs, seem likewise to be one of the histological peculiarities of the Coelacanths.

From the point of view of biology, some quite recent complementary investigations which I have just carried out with Commander Cousteau and his team from the *Calypso* confirm that the modern Coelacanths inhabit, around the Comoro Islands, basalt rocky bottoms which slope very steeply (25°–45°). They seem to live normally on the actual bottom or quite close to it, between 200 and 400 metres depth at least; specimen C^4, for example, was taken fifty centimetres from the bottom in a depth of 370 metres and over a slope of 45°. But there is every possibility that their habitat may extend very much deeper still. It would be as well, in fact, to emphasize that fishing off the Comoro coasts has never yet been carried out beyond 370–380 metres depth, and that two of these fishes have been taken at that extreme limit. The fact, moreover, that among the five specimens captured there is no adult female leads us to believe that these may be out of reach because they live at a depth of more than 400 metres.



Complete transverse section through the anterior quarter of the abdominal viscera of Coelacanth C^4

Note, in the centre of the upper portion, the oesophagus (wrinkled opening) and, closely applied to its ventral surface, the vestige of the pulmonary organ, represented by a fatty crescent-shaped mass centring around a very short tubular diverticulum. The centre of the photograph is occupied by the two large hepatic lobes, here very dark. Below these lies the spiral intestine. At the very bottom of the illustration is the narrow pyloric region of the stomach with, to its left, the pancreas, which is triangular in section

Preparation made with the collaboration of Dr. Decérisy. Photo: J. M. Banflé

An attractive theory has been formulated in Grand Comoro, where the last three specimens were taken: namely, that the Coelacanths live in the upwellings of fresh water off that island, the hydrographic conditions of which are very peculiar. There is a great deal of rain—more than 5 metres rainfall per annum in certain places—but nevertheless the island suffers from a serious and permanent shortage of water. There is not a single river, and even after the heaviest downpours there is an almost complete absence of surface water; this is because the soil is formed of very permeable volcanic scoria into which practically the entire rainfall is absorbed. This then flows away into the sea by a multitude of coastal springs and important submarine upwellings, in such a way that during a spell of drought, when the level of the reservoirs falls in the most alarming manner, the people often come at low tide to draw water from these littoral springs. Now Coelacanths, as we know, have during long periods in the past lived in brackish or nearly fresh waters—from which comes the very interesting notion that they may have been able to survive among the Comoros, and among the Comoros only, because the submarine upwellings of fresh water would have assured them the maintenance of their ancestral environment at depths where reduced competition allowed them a better chance of existence.

Unfortunately, the most ingenious explanations are not always the true ones. This one does not seem to be tenable because, for one thing, the upwellings in question do not seem to occur except in the intertidal zone; and again, because also the seawater samples taken by my collaborator Menaché in the places where the Coelacanths of Anjouan were captured have revealed quite normal marine salinities. Further, there is every likelihood that the samples of water which have just been obtained by the *Calypso* at the location and depth at which the first Coelacanth of Grand Comoro was taken will produce similar results.

NEWS and VIEWS

James Cook Medal of the Royal Society of New South Wales: Sir David Rivett, K.C.M.G., F.R.S.

THE Royal Society of New South Wales has awarded the James Cook Medal for 1953 to Sir David Rivett. The presentation was made by the president of the Society, Prof. R. S. Nyholm, of the N.S.W. University of Technology and professor-elect of chemistry in University College, London. Prof. Nyholm remarked that Sir David Rivett, after graduating at the University of Melbourne, proceeded in 1907 as a Rhodes Scholar to Oxford. At Oxford, and later at the Nobel Institute, Stockholm, he carried out research in physical chemistry. He returned to Australia as lecturer in chemistry at the University of Melbourne in 1911, where he succeeded Sir David Orme Masson in the chair of chemistry in 1924. His main research interests were in the field of heterogeneous equilibria, to which he made many major contributions. Rivett had frequently stressed the importance of scientific research in the development of Australian primary and secondary industries. It was not surprising, therefore, that when the Institute of Science and Industry was reconstituted in 1926 as the Council for Scientific and Industrial Research, the Commonwealth Government appointed him as the chief executive officer and deputy-chairman. The success of the Council (now the Commonwealth Scientific and Industrial Research Organization) has been due, in a large measure, to Rivett's vision and leadership. Many difficulties were encountered in the formative years through Federal and State jealousies, impatience of politicians expecting quick results, and the often niggardly provision of money by Governments. Rivett overcame these difficulties by his persuasiveness in negotiation, courageous public utterances and his high personal and scientific integrity. The growth of fundamental research work in the Council was constantly encouraged by Rivett and, by the time he retired from direct work with the Council in 1949, fundamental studies occupied a major part of its activities. Rivett's leadership in science has been recognized by the conferring of a knighthood in 1936 and election to fellowship of the Royal Society in 1941. He was president of the Australian and New Zealand Association for the Advancement of Science during 1936–39 and president of the Society of Chemical Industry of Great Britain in 1950. The James Cook Medal is awarded annually "for outstanding contributions to Science and Human Welfare in and for the Southern Hemisphere".

Indian Independence Day Decorations

AMONG decorations awarded by the President of India on Independence Day were the following:

The Bharat Ratna to Sir C. V. Raman, F.R.S., director of the Raman Research Institute, Bangalore.

The Padma Vibhushnan Pahela Varg (first class) to Dr. S. Bose (physicist) and Dr. Z. Hussain (educationist).

The Padma Vibhushnan Dusra Varg (second class) to Dr. H. J. Bhabha, F.R.S., director of the Tata Institute of Fundamental Research, Bombay; Sir Shanti S. Bhatnagar, F.R.S., secretary to the Ministry of Natural Resources and Scientific Research and director of Scientific and Industrial Research, Government of India; and Sir K. S. Krishnan, F.R.S., director of the National Physical Laboratory of India, New Delhi.

Agriculture at Reading: Mr. A. N. Duckham, C.B.E.

THE appointment of Mr. A. N. Duckham to the chair of agriculture at Reading in succession to Prof. H. G. Sanders (see *Nature*, April 10, p. 662) will be warmly welcomed. From the Agricultural VI at Oundle he went in 1922 to Cambridge, where he took the Natural Science Tripos and the diploma in agriculture. In the latter he obtained the very rare 'distinction', and an essay based on his thesis work on baby beef was awarded the silver medal for research by the Royal Agricultural Society of England. From 1927 onwards he was concerned mostly with pigs at Cambridge (where with Mr. H. R. Davidson he started and ran the East Anglian pig recording scheme), Belfast and Aberdeen, and in 1935 he became the research officer of the Bacon Development Board. In addition, he carried through two special assignments with conspicuous success: a survey of the economics of grass drying for the Empire Marketing Board, and the preparation of an account of animal industry in the British Empire which involved much travel. War brought service with the Ministry of Food as chairman of that Ministry's agricultural committees and collaboration with Sir Jack Drummond on dietary problems in Great Britain and other countries. He attended the Hot Springs Conference in 1942 and has continued as agricultural adviser to the United Kingdom delegation to the U.N. Food and Agriculture Organization. In 1945 he was appointed agricultural attaché at Washington, where he was extremely successful. After his return to become head of the General Division of the Ministry of Agriculture, he produced a monograph on American agriculture which is held in very high esteem. The University of Reading will gain one whose knowledge of agriculture is almost world wide, and whose interests also include painting and music.

Bernard Price Institute of Geophysical Research, Johannesburg: Prof. A. L. Hales

THE University of the Witwatersrand has appointed Prof. A. L. Hales to succeed Dr. B. F. J. Schonland as director of the Bernard Price Institute of Geophysical Research, Johannesburg, when the latter leaves on October 1 of this year to take up his new position in Britain as assistant director of the Atomic Energy Research Establishment, Harwell. Prof. Hales, who at present occupies the chair of applied mathematics in the University of Cape Town, took his M.Sc. degree at the University and then proceeded to Cambridge, where he studied under Sir Harold Jeffreys. His first university appointments were in the Departments of Mathematics and of Applied Mathematics at the University of the Witwatersrand. After war service, including geophysical work in the Middle East theatre, he served on the staff of the Bernard Price Institute during 1945–49 before proceeding to Cape Town. Prof. Hales has made a number of important contributions to geophysical subjects connected with the crustal structure of the earth and the theory of mountain building. Some years ago he carried out a gravity survey of southern Africa in association with Dr. D. I. Gough.

National Institute of Agricultural Botany, Cambridge: Report for 1953

At the annual general meeting of the Fellows of the National Institute of Agricultural Botany, Cambridge, on July 16, the chairman, Prof. T. J. Jenkin, presented the annual report of the Council for the year ending December 31, 1953 (pp. 48. From the Institute), and referred to some new developments in the work of the Institute proposed for the future. From the report, it is evident that the year under review was one of both progress and consolidation, and the improved staffing, authorized by the Ministry of Agriculture in 1952, has been fully implemented. Since publication of the results of field trials is one of the Institute's chief concerns, it is satisfactory that two issues of its *Journal* appeared during the year, together with new or revised editions of seven "Farmer's Leaflets", while interim comments on the performance of some seventy different varieties of cereals, varieties or strains of root and fodder crops, beans, peas, vegetables and potatoes were available in the report itself. Development of the Field Inspection and Certification schemes co-ordinated by the Seed Production Committee of the Institute continued, and the acreage of cereal seed crops inspected under the Field Approval Scheme reached a total of 66,000 in 1953, compared with 26,800 in 1947.

As regards the future, Prof. Jenkin announced that the Ministry of Agriculture has agreed to the request of the Welsh Plant Breeding Station that the Institute should accept responsibility for the production of stock seed and for the certification of the Aberystwyth strains of grasses and clovers. It is recognized, however, that two or three years must elapse before the necessary equipment and facilities can be provided to enable the Institute to undertake full responsibility in this matter. Developments in the international field are also contemplated, for help of the Institute has been sought by the Organization for European Economic Co-operation to co-ordinate two new projects. The first of these is a scheme for international grass strain trials designed to test the value of strains. This will involve three stages—namely, identification and classification, preliminary assessment and agronomic trials—and will be undertaken in close co-operation with the Grassland Research Station at Hurley. The second is an attempt to obtain greater uniformity in the terminology used to designate the different stages of herbage seed production, for at present each country has its own system, and confusion is liable to occur with regard to certification schemes. The meeting concluded with an address by Sir John Russell (see p. 446 of this issue).

The Royal Botanic Gardens, Kew

With the publication of the first number of the *Kew Bulletin* for 1954, the work of the Royal Botanic Gardens, Kew, during 1953 is reviewed in some detail. This is a matter of general interest, to the public and to professional botanists alike. During the year the centenary of the Herbarium and Library was celebrated by an exhibition illustrating the work of these Departments during the past hundred years (see *Nature*, 171, 1086; 1953). The continuing activity of the herbarium is well illustrated by the following statistics: specimens received from outside sources, 60,496; sheets received on loan, 4,558; sheets sent on loan, 4,446; sheets distributed as duplicates, 12,268; sheets mounted (with certain exclusions), 46,465; and so on. Visits by botanists numbered 3,964. Inquiries and plant consignments dealt with numbered 2,667. In the midst of the routine tasks, of which there are many, the long-term projects have been pursued, for example, the preparation of the "Flora of Tropical East Africa", and other floras, and members of the staff have taken an active part in contemporary botanical and other activities. Special work on particular systematic groups has also been undertaken, for example, Bignoniaceae, Orchidaceae, vascular cryptogams, etc. An outstanding event of the year was the publication of Supplement XI (1941–50) of the *Index Kewensis*, and progress has been made with the succeeding volume. The work of the Library, the Museum and of the Jodrell Laboratory, where work on the systematic anatomy of the monocotyledons is being steadily pursued, as well as routine inquiries, some of a curious character, is also reviewed. In the Gardens, the work in the arboretum, the alpine and herbaceous sections, and the temperate, decorative, tropical and other departments is recorded and discussed. The *Bulletin* concludes with a list of publications and the roll of scientific and administrative staff.

Science in China To-day

An interesting but pessimistic appreciation of the position of scientists in Communist China is contributed to *Science* (119, 785; 1954) by A. Z. Chang, now working at the Centre for International Studies, Massachusetts Institute of Technology. Reviewing the education and activities of those of the fifty scientific workers constituting the national committee of the 'Ko-lien' (All-China Association for Natural Sciences) for whom information is available, Dr. Chang points out that their average age so far as is known is more than fifty-five years, and none is a product of post-war education. Of the eleven institutes within the Academia Sinica, six are directed by leading scientists who are members of the 'Ko-lien' National Committee and three others by scientists who are not members of that Committee. Most of these leading scientists retain their teaching positions while serving in government positions; of the fifty members of the 'Ko-Lien' National Committee, fifteen retain full-time professorships and five serve on committees. A few hold key positions in functional departments. Throughout the Second World War there was no evidence that the Communists made any progress in training or absorbing scientific personnel, while the leading scientific workers of the older generation are being subjected gradually to as great pressure as any other intellectual group. Dr. Chang considers that the most serious challenge is the particular Communist concept of science in general and the Communist inherent antagonism against 'bourgeois science' in general; in main construction projects the Communists rely more on their ability and ruthlessness in organizing masses than on technical knowledge. Indigenous technology and the scientific approach on the China mainland are in a highly State-controlled condition to-day, and the future of science in this area is likely to conform to that within the general Soviet pattern.

Scientific Research in South African Universities

The Library and Information Division of the Council for Scientific and Industrial Research, Pretoria, has published a "Register of Current

Scientific Research at South African Universities" (pp. 212; 1953), this being the second volume, the first volume, covering research in progress during 1951, having been issued in 1952, and it is hoped to issue the register annually in future. It is a companion to the "Register of Current Research in the Humanities", issued annually since 1946 by the Council. Investigations are arranged by subjects according to the university department, with occasional cross-references, and the departments are listed alphabetically under their English names. Details of the scope of the investigations are given in the language in which it was received from the university department, but the omission to translate subjects or titles consistently into English somewhat militates against the usefulness of the register. Particulars of the qualifications and status of the investigator and of the director of the investigation are included.

East African Research Board: Report for 1953

THE eleventh annual report of the East African Industrial Research Board of the East African High Commission (pp. 11. Nairobi: Government Printer, 1954) covers the year ended December 31, 1953, and records good progress in the project to extract hecogenin from sisal waste on a pilot scale. Pure hecogenin acetate is now becoming available in the United Kingdom in research quantities for the synthesis of cortisone and related compounds, and a hydraulic press and extrusion cylinder has been designed for the expression of juice from sisal waste which should prove more efficient than the squeezing rolls hitherto used. Work on the refining of sisal wax indicates that fractional extraction with alcohols will yield more highly coloured fractions first, which might be used where colour is unimportant, and that later fractions might be used to obtain a paler product. The method of pelletizing fine kainite for heating in a rotary kiln has been worked out on a commercial scale, and the addition of alumina as bauxite has proved to be the most reactive for converting the silica, released from the kyanite molecule on calcining, to mullite. Detailed performance tests have been made on the use of wood producer gas in dual-fuel diesel engines, but experiments on the fermentation of sisal waste and papyrus roots and stalks to give combustible gases had to be suspended, although yields of 400–500 c.c. gas containing about 60 per cent of methane and 40 per cent carbon dioxide can be expected per gram of dry sisal waste with an output 0·9–1·5 times the volume of the digesting mass per day. Preliminary experiments indicate the possibility of producing pepsin of more consistent quality by processing the latex obtained from the juice of the pawpaw fruit. Trials with a Swiss mechanical briquetting machine indicated that the machine was unsuitable for handling coffee parchment, cotton seed husk and brine coffee husk without further treatment, but excellent briquettes were obtained from sawdust and satisfactory briquettes from brine coffee husk which had been passed through a disintegrator. An investigation into the whole process of coffee curing was commenced.

National Foundation for Scientific Research, Brussels: Report for 1952–53

THE twenty-sixth annual report of the National Foundation for Scientific Research, Brussels, covering the year 1952–53 (pp. 231; 1954), records the completion under the Inter-university Microfilm Commission, created in October 1949, of an inventory of microfilms in the archives of the French Departments of Lille and Dijon, copies of which are deposited in each of the Belgian universities. The Council made a third grant of 1,485,000 francs to the Special Commissión for Clinical Research, which has been distributed by the Commission among the four university centres engaged in work on cortisone and adrenocorticotropic hormone, and brief reports from each centre on this work, with a list of publications, are included. A sum of two million francs was put at the disposal of the Royal Observatory of Belgium for the establishment of a radioastronomy laboratory. Brief accounts are included of the work on calculating machines at the Universities of Brussels, Ghent, Liège and Louvain, for which a further credit of 50,000 francs has been voted, while 200,000 francs were voted for the reconstruction of the Marine Biology Station at Wimereux, destroyed during the War. Ninety-three grants, totalling 247,289 francs, were made to assist Belgian scientists and research workers to attend overseas conferences and meetings. Extraordinary credits granted during the year, totalling 6,110,000 francs, included two million francs to the Inter-university Microfilm Commission, 25,000 francs to the International Institute of Meteorology, Stockholm, 50,000 francs to the Zoological Station, Naples, and 250,000 to Prof. R. de Langhe for his archæological expedition to explore systematically the grottoes of the borders of the Dead Sea and the desert of Judea in Palestine. Lists of recipients of research grants for 1953–54 and of publications during 1952–53 by recipients of grants are included. The report includes an account of the distribution of radioisotopes in Belgium and the researches carried on by this means in the university laboratories and at the Institute of Cancer, as well as in the Polytechnic Faculty of Mons, the State Agronomic Institute at Gembloux and in industry and horticulture.

Central American Scientific Institutions and Scientists

A FIRST list for Central America in the series "Scientific Institutions and Scientists in Latin America", covering Costa Rica, El Salvador, Guatemala, Honduras, Nicaragua and Panama (pp. 202; 1954), has been issued by the United Nations Educational, Scientific and Cultural Organization, at Montevideo. The list was prepared by the Organization's Field Science Co-operation Office for Latin America, with the collaboration of Ibero-American organizations, and is expected to be completed in several volumes during the next few months. Under each country are given lists, in Spanish, first of institutions and second of scientific workers; these include the address of the institution and some details of its functions, interests and officials, and, for the scientists, of their special interests, career and publications.

The Scientist: A New Pakistani Journal

IN Nos. 2 and 3 of the first volume of a new journal, *The Scientist*, which has recently been started in Pakistan, there are articles upon the following topics: the agricultural industries of Pakistan; the problem of Pakistan railways; symmetrical incomplete block designs; a field key to the identification of fishes; the biology of a mango defoliator; and the theory of liquids. *The Scientist* is published by the Department of Zoology, University of Karachi, the chief editor being Dr. M. A. H. Qadri.

Scientific Literature in New Delhi

THE "Insdoc List of Current Scientific Literature", the first issue of which is dated June 1, 1954 (pp. 16. New Delhi: National Scientific Documentation Centre; Rs. 10 a year), is being published semi-monthly to inform scientific workers in India and neighbouring countries of the latest papers published in some two hundred and fifty leading scientific and technical periodicals of the world. It also includes information on scientific reports received at the National Physical Laboratory—Insdoc Library, New Delhi, as well as the titles of translations available or on which information has been received. Titles of papers in languages other than English are given in English translation. The entries are arranged in broad subject groups according to the Colon Classification, but Universal Decimal Classification numbers are also given.

Bibliography of French Biological Books

THE first issue (No. 9, December 1953) of the second series of the "French Bibliographical Digest", which is planned to give a selected bibliography of significant scientific and technical books, of at least university level, published in France since 1949, includes an article by Prof. L. Plantefol on botany in France to-day and a list of French scientific and technical periodicals. Under each subject the abstracts or reviews of each book are given alphabetically by authors, and there is also an index of authors. The entries in this issue are limited to biology, botany and zoology, and the Digest is intended primarily to introduce French books to the United States. It will be supplied free, upon request, to libraries, university departments and scientific workers who indicate the subjects in which they are interested. It is edited and published by the Cultural Division of the French Embassy, 972 Fifth Avenue, New York City, 21.

Yale Medical Library and Historical Library: Report for 1952–53

THE annual report of the Yale Medical Library, which includes the report of the Historical Library, for the year ended June 30, 1953 (pp. 47. New Haven, Conn.: Yale Medical Library, 1953), stresses changes made to increase the availability of periodicals. The 'current use' of a periodical appears to continue for about five years, the second year after publication being the time of heaviest use and also the time when the periodical is at the binders. Two periodicals were used as much as 158 of the least popular on the list combined, and with thirty-eight others these two periodicals accounted for nearly 50 per cent of the use made of periodicals. By duplicating subscriptions to the more heavily used periodicals, discontinuing the binding of four hundred little-used periodicals, restricting the more complete set to use within the Library, and certain other changes, it is hoped to check the sharp decline in the recorded use of the Library. A list of periodicals available in the reading room is appended, and the report of the Historical Library gives details of important accessions during the year.

The Early Developments in Atomic Energy

AT the meeting of the Education Group of the Institute of Physics on October 20, 1953, Prof. O. R. Frisch, of the University of Cambridge, who was one of the pioneer workers in the atomic energy project during the Second World War, delivered an interesting talk on "Atomic Energy—how it all Began". The text is reprinted as a special article in the March number of the *British Journal of Applied Physics* (5, 81; 1954). Prof. Frisch gives a brief review of important developments following the first direct manifestation of atomic energy by Becquerel in 1896, in particular of Rutherford's 1912 picture of the atomic nucleus and of Chadwick's discovery of the neutron in 1932. He then discusses why physicists with all the data available in 1935 did not discover fission at that time. Next, the exciting events which followed Hahn and Strassmann's publication in 1939 are most vividly told, and Prof. Frisch includes some personal reminiscences of details of his conversations and discussions with Prof. Lise Meitner. Finally, the feasibility of controlled and explosive controlled reactions and the development of controlled nuclear reactors are discussed. Prof. Frisch concludes by remarking that he likes to remember the days when chain reactors were a new toy for physicists to play with and recalls how for a few exciting weeks in Los Alamos he and others were allowed to study the growing amounts of uranium-235 which were then being prepared for the first atomic bomb.

Diamond Tool Industry during 1953

AN eight-page brochure, entitled "The Diamond Tool Industry in 1953", issued free of charge by the Industrial Diamond Information Bureau, 32–34 Holborn Viaduct, London, E.C.1, is the ninth in the series of reports on the diamond tool industry and summarizes the main developments during 1953 under the following headings: physical properties; hardness; surface finish; fine boring and turning; trueing of grinding wheels; diamond powders; impregnated diamond tools; sintered carbide grinding; glass grinding and stone working; rock drilling; wire drawing; diamond use and salvage; new machining methods; and jewel bearing production. Reference is made to 155 articles, and a detailed bibliography is appended. The report, which will be of interest to all those engaged in the use and production of diamond tools, has been compiled from the monthly "Bibliography of Industrial Diamond Applications", also published by the Industrial Diamond Information Bureau.

Protecting Cleaned Iron Objects

IN the *Museums Journal* of May 1954, L. Biek, E. S. Cripps and D. M. D. Thacker, of the Ancient Monuments Branch, Ministry of Works, describe a series of experiments undertaken to protect iron objects that have been cleaned. Some keys, of the eighteenth to early nineteenth centuries, were used. All were heavily rusted, with some deep pockets of hard oxide. The keys were cleaned in an inhibited phosphoric acid formulation ('Deoxidine No. 125', I.C.I.) and scrubbed with steel wire brushes to remove the rust. They were then soaked in acetone to prevent the formation of the rust-coloured film which appears when wet ironwork dries in air. Various protective coverings were then applied, including bleached beeswax, chlorinated rubber solution, celluloid solution, polyvinyl acetate solution in toluene, polymethacrylic ester solution ('Bedacryl' 144 TL., I.C.I.) and graphite powder rubbed into the surface. The amount of rusting was assessed and other factors, such as convenience, cost, time and appearance, were taken into account. By and large, waxing seems to have a slight advantage over steel wire brushing followed by 'Bedacryl'; coating with polyvinyl acetate and the graphite/'Bedacryl' treatment are also satisfactory.

Education for Management

The British Institute of Management has now published the second of the booklets dealing with education and training in the field of management. The first was concerned with the facilities available in technical colleges and other educational institutions, while the second describes short courses held at residential establishments and by professional and other bodies. These include courses for senior management organized at the Administrative Staff College and by the National Council of Y.M.C.A.'s; courses for middle management and other supervisors arranged by certain professional and voluntary organizations, adult education colleges, university departments and such bodies as the Hull Junior Chamber of Commerce; courses for young workers, apprentices and other entrants to industry, organized mainly at residential educational colleges; courses for trade unionists organized mainly by the National Council of Labour Colleges; as well as courses in such topics as joint consultation, communications, work study and method engineering held at a variety of centres. The booklet also contains details of special courses arranged for education, training and personnel officers. The sponsors of the booklet are to be commended both for undertaking such an important work and for the succinctness and accuracy of their presentation.

The Fourth Douglas Lea Memorial Lecture

The fourth Douglas Lea Memorial Lecture, entitled "Douglas Lea: Physicist into Biologist", will be delivered by Prof. C. A. Coulson, Rouse Ball professor of applied mathematics in the University of Oxford, at a meeting of the Hospital Physicists' Association on October 1 in the Reid-Knox Hall of the British Institute of Radiology, 32 Welbeck Street, London, W.1, at 8 p.m. The meeting is open to the public.

Announcements

The eighth annual congress and festival of scientific films of the International Scientific Film Association will be held in Rome during November 6–12 at the University City and also at the National Research Council. Public performances of outstanding films of general appeal will be given, and specialized films will be shown and papers read at the meetings of the sections concerned with the film in medicine and veterinary science, in industry and technology, in scientific research, and in other subjects. Inquiries in Britain concerning the congress should be sent to the Scientific Film Association, 164 Shaftesbury Avenue, London, W.C.2. All other inquiries should be sent to the Segreteria VIII Congresso Internazionale della Cinematografia Scientifica, Commissione per la Cinematografia Scientifica del Consiglio Nazionale delle Ricerche, Piazzale delle Scienze 7, Roma.

The fourth annual Eastern Joint Computer Conference and Exhibition, which is jointly sponsored by the American Institute of Electrical Engineers, the Institute of Radio Engineers and the Association for Computing Machinery, will be held in the Bellevue-Stratford Hotel, Philadelphia, Pa., during December 8–10, the theme this year being the "Design and Application of Small Digital Computers". Proceedings of the Conference will be published by the sponsoring societies and may be ordered from any one of them. The meeting will be open to all. Applications for registration should be sent to the Eastern Joint Computer Conference, P.O. Box 7825, Philadelphia 1, Pa.

The Iron and Steel Institute, in association with the Institute of Metals, is organizing a symposium on powder metallurgy, to be held in Church House, Westminster, London, S.W.1, during December 1–2. Both ferrous and non-ferrous aspects of powder metallurgy will be considered, and there will be a small exhibition of components used in the various processes. The papers will be divided into three groups: metal powders and their assessment; research and production practice; and production and properties of engineering materials. The symposium will be open to all, whether or not they are members of either Institute, on application to the Secretary of the Iron and Steel Institute, 4 Grosvenor Gardens, London, S.W.1, from whom further information can be obtained.

The autumn conference of the Scientific and Technical Group of the Royal Photographic Society will be held this year on October 2 in the Lecture Theatre of the Stephenson Building, King's College, Newcastle upon Tyne, in conjunction with the University of Durham. The theme will be "The Scientific and Technical Applications of Photography", and, besides the reading of eight papers, visits will be made to the Departments of Naval Architecture, Physical Chemistry, and Photography of King's College. The conference will be open to all, no tickets being necessary. Further information can be obtained from Mr. C. J. Duncan, Director, Department of Photography, Medical School, Newcastle upon Tyne 1, or from the honorary conference secretary of the Scientific and Technical Group, Dr. R. S. Schultze, Research Library, Kodak, Ltd., Harrow, Middlesex.

The Edison Swan Electric Co., Ltd. (155 Charing Cross Road, London, W.C.2), has published the third in its series of educational booklets, entitled "Electrons", this latest one being on screened-grid and pentode valves. It surveys the disadvantages of the triode in order to show how, for certain purposes, improvement can be obtained by an additional grid as in the screened-grid or tetrode valve, and by two additional grids as in the pentode. In addition to explanatory circuit diagrams, the booklet contains a specially prepared sectional drawing of the Ediswan Mazda high-slope screened radio-frequency pentode 6F1 valve, showing the electrode assembly and full details as to its operating conditions.

The "Bibliography of Articles appearing in Turkish Periodicals, No. 5" (pp. 138. Istanbul: Milli Egitim Basimevi), covering the period October–December 1952, contains some nine hundred entries, arranged according to the Universal Decimal Classification (first two figures only), and alphabetically by authors within each section. Slightly more than half the entries fall under science and applied science or technology. A list of periodicals covered, with the place of publication, and an author index are included, and the explanatory preface is in Turkish and in French.

BRITISH ASSOCIATION MEETING AT OXFORD

SCIENCE AND HUMAN NATURE

By Dr. E. D. ADRIAN, O.M., P.R.S.

PRESIDENTIAL ADDRESS

THREE hundred years ago a scientific society used to meet in Oxford every week in the rooms of Dr. Wilkins of Wadham College. It was the first of its kind in Britain and it had what we should now call an escapist motive. Fifty years before, Francis Bacon had published his great plan for a new road to knowledge, by concerted observation and experiment, and Harvey soon after had made the experiments which proved the circulation of the blood. But then the country had been torn by civil war. It had killed its King and could not see how to reach settled government. Dr. Wilkins had collected a band of scholars of inquiring mind, Boyle, Wren, Willis and others whose names are now part of the history of science, and they met together to take what comfort they could in the new kind of knowledge which could be confirmed by experiment instead of the appeal to authority. "Their first purpose was no more than only the satisfaction of breathing a freer air and of conversing in quiet with one another without being engaged in the passions and madness of that dismal age."

So it was in Oxford that the scientific age was conceived in England, with the conflicting loyalties of the Commonwealth as a background, and I can admit Oxford's claim the more cheerfully because Dr. Wilkins moved to Cambridge and was for a short time Master of Trinity College, just before Isaac Newton came there as a young undergraduate.

When the King came to his own again the temper of opinion changed. There were great prospects ahead. The philosophers moved to London, convinced that their inquiries would lead to material prosperity as well as to deeper knowledge. They founded the Royal Society, and Isaac Newton's "Principia" established the mechanical order of the world. The material progress followed more slowly; but one hundred years after Newton's death it had already begun to affect the lives of half the people in Britain. Scientists, as usual, were in no doubt about the value of what they were doing and they felt it was high time to share their faith and some of their responsibilities.

In 1831, therefore, the British Association was founded for the advancement of science and at the annual meeting our leading scientists assembled in one big town after another to spread the news of this fresh source of knowledge and of material advance; and the Association has gone round ever since on much the same errand, announcing new discoveries and airing controversies before an audience which has grown steadily in size and in its understanding of what the scientists are about.

But now the products of science are everywhere. Knowledge of the material world is constantly growing, and its consequences are of such a spectacular nature that everyone is aware of them: few people now can doubt that the scientist's picture of the world must have some validity if it enables him to deliver such remarkable goods. So it has come about that the advancement of science is in everyone's mind. Why then are we here to-day? What is there left for the British Association to do if it can only preach to the converted?

For scientists it can do a great deal. We are all specialists nowadays, and here we can learn what is happening in fields outside our own; but it is true that these meetings must lack some of the appeal they had when the whole territory of science was so much smaller. Progress is too rapid for the new discoveries to be saved up as a birthday present, and controversies have become too technical to be aired in the market place. Yet there is one very great and worthy task which needs the help of a body like ours which brings scientists and laymen together. The Association must show the layman where the scientific age is leading him. It is by its impact on public opinion that the success of these meetings must be judged.

No meeting of the Association at Oxford could pass without reference to that famous occasion when its impact on public opinion was highest, when it was made quite clear that the pursuit of natural science would mean a painful revision of beliefs as well as a gain of material comfort, when it claimed acceptance for the theory that denied the special creation of mankind.

It was in 1860, the year after the publication of Darwin's book on "The Origin of Species". Bishop Wilberforce was to speak and Huxley was Darwin's champion. The audience was too large for the lecture room and they moved to the long west room of the Museum; but the first paper was dull, it was on "The Intellectual Development of Europe considered with reference to the views of Mr. Darwin", and after an hour of it the audience was restless and wanted something more dramatic. They had it from the Bishop, who spoke with eloquence and wit against the idea that man and the monkey could have a common ancestor. He ended with an ill-conceived joke about Huxley's claim that he was descended from the apes; but he sat down to general acclamation and the fluttering handkerchiefs waved by the ladies. Huxley had a more harshly coloured picture to present: the aim of life was merely to go on living, the road to progress was by the slaughter of the weak and the survival of the strong, and man was cousin to senseless brutes. The scientists were demanding that the search must go on, that the evidence must be followed wherever it led, but until then it had not led to anything quite so bleak.

All this was no doubt implicit in Huxley's speech; but the audience at the British Association is human and what really stirred them was Huxley's grand indignation at the idea of a bishop condescending to such a paltry joke on so high a theme. His scorn forced the excitement to such a pitch that one lady fainted and had to be carried out, and afterwards no one, not even Huxley, could remember exactly what he had said. It did not matter so much, for the chief issue was no longer the origin of species, but whether Bishop Wilberforce had really been guilty of a breach of good manners. But the dispute had been on the scientific plane and the evidence could not be ruled out because it was unpalatable:

within a few years the battle for Darwin's theory was won and it seemed that the discoveries of science had forced the human race to give up beliefs on which it had relied for centuries.

Naturally the change came gradually, bringing discord into a good many families where the rising generation were zealous converts to the new creed. But now the scars are mostly healed. Advancing understanding of what was really at stake has made it possible for both sides to keep their ideals. The theory of evolution has lost its power to arouse passionate resentment or passionate faith.

I have mentioned that meeting for two reasons: because it emphasized that man himself was part of the natural world and because it emphasized also his right, at all events his determination, to go on searching for knowledge, for without his curiosity he would be nothing.

We all know where our curiosity has now landed us: with advances in atomic physics which might be applied to devastate half the world, and if they were so applied would certainly make life in the other half extremely precarious. Our grandfathers here were faced with scientific discoveries which were no laughing matter, for to many of them they spelled the end of all worthy human aims; but we face discoveries which might spell the end of all human aims, worthy or not.

We can regret that atomic bombs are possible without regretting the discoveries that have led to them. Advances in natural science cannot avoid advancing the methods of warfare; they do so when they make armies more healthy as well as when they increase the power of their weapons. But although the strategists have to think mainly of immense explosions and great devastation, it would be a mistake to suppose that these are the only dangers. Even if we can survive them we must face the possibility that repeated atomic explosions will lead to a degree of general radioactivity which no one can tolerate or escape.

The level would not rise rapidly and there is a large margin in hand; but the physicists can estimate the persistent contamination which must follow an atomic explosion of a given magnitude and the biologists can assign limits to the amount of contamination which could be let loose on the world without serious danger to every part of it. When atomic energy is used for supplying power for industry the dangers of contamination are real enough, but due precautions can be taken to avoid them. In a major war they would soon be set aside. Powerful nations who think they could win quickly might accept the risk. A few hundred large bombs would not raise the level of radiation to the point where it would become a general danger, and no doubt a country of small area like ours could be reduced to ashes by a relatively small mass of explosion. Though the ashes would be deadly, the rest of the world might escape them. But a long war between powers well armed with bombs would certainly involve an order of radioactive contamination which would involve us all—victors as well as vanquished.

Arguments that war does not pay will not count much when ideals are threatened. It is true that a war which would probably end in wholesale destruction can appeal only to people who are desperate; but they can be made desperate and that is the end we have to guard against. There are conceivable safeguards, of course; but controls and conventions are not foolproof, and in future whenever the world is split into two opposing groups with large stores of atomic weapons it must face this added risk of catastrophe.

Yet we have surely no right to feel that our predicament is so much worse than that of earlier generations. Our grandfathers could do nothing to ward off the danger which seemed to face their cherished beliefs; but our fate is in our own hands. We are afraid, and rightly, because we cannot trust ourselves to act peaceably, because we know that unless we are ready to give up some of our old loyalties we may be forced into a fight which might end the human race. Our predicament is the inevitable result of our curiosity and of the physical nature of the world we live in; but if we can make our behaviour worthy of our increased knowledge we can live safely. The scientist, therefore, has a double responsibility. He must apply his science to learn as much as possible about the mental and physical causes which make us behave as we do, he must study human nature to prevent its failures; but he cannot wait for the discoveries which might make us act more wisely: he must take us as we are and make it his task at meetings like this to point out that the human race cannot stand more than a few thousand large atomic explosions whether they hit their target or miss it. If we can make this known universally our Association will not have failed in its purpose.

It may be optimistic to think that our dangers would recede if we had a better understanding of human reactions: in fact, if we must continue to make war there is no kind of scientific investigation which might not be used for making it more effective, and there can be no guarantee that discoveries in the field of human conduct would be harmless. A drug or a system of education which would make us all do as we are told, a method of producing radical conversion to a new system of belief, a knowledge of new ways of rousing patriotic ardour, all these might be used with consequences almost as grim as the genetical deterioration in a radioactive world. The psychiatrist who discovers a cure for paranoia may find that he has also revealed a convenient way of producing it.

Our novelists have made us aware of these dangers; but it is some comfort to feel that in this case the increased knowledge could be used for defence as well as attack. We can only be protected from radioactivity by living in caves on uncontaminated food and drink; but an increased knowledge of how the mind can be influenced could certainly forestall many of the influences which might be used for undermining our integrity.

It is certainly true that discoveries relating to our own nature may mean a painful readjustment of our beliefs: that, however, is a fair price for increased understanding and, in fact, our ideas about our own behaviour have already been assailed in such a way that further revelations are unlikely to shock us. There is a fairly close parallel between the impact of the theory of natural selection one hundred years ago and that of Freud's theories on our own generation. The British Association does not come into it, because Freud's evidence was all on the medical side; but his views made the same kind of attack on our pride and met with the same passionate resentment or approval. The theory of unconscious forces moulding our thought has certainly diminished our stature as intelligent beings; yet the parallel still holds, for again we have recovered our equanimity.

We are reconciled to the unconscious, though we may not have digested all the elaborations of psychoanalytic theory. We are no doubt less sure of ourselves, inclined to spare the rod and to put nothing in its place; but, on the whole, Freud has left us with a better understanding of human conduct and we are not down-hearted at finding it less rational then we used to suppose.

Freud would have liked to build up a system based on the physiology of the brain; but he was soon too deeply committed to the psychological side. Pavlov's conception of human behaviour was based on brain physiology and it was less disturbing because it did not go into such uncomfortable detail. It is now perhaps more disturbing than Freud's, because Pavlov's notion of the conditioned reflex has come to dominate one side of the world; but we must not think the less of it because it has been used for justifying a political system foreign to ours. Pavlov and Freud were both scientists of surprising originality. They gave a new impetus to research on human activity; but the fields they explored are still waiting for the next advance to show how much they will yield.

The difficulty is that there are so many fields of inquiry to cover, each with its own limited range of facts and deductions. Freud studied dreams and neuroses and explained them as the product of repressed desires. Pavlov studied learning in animals and explained it in terms of conditioned reflexes. But physiologists ever since Galvani have studied the reactions of nerve fibres and nerve cells, the units of the nervous system, in the hope of explaining what they do in the terms of physics and chemistry. This approach at the lowest level can tell us little about the way in which units are organized; but when we keep to physical and chemical problems we are in the familiar territory of the exact sciences, we know how experiments should be conducted and there are great technical advances at our disposal. It is when we begin to think of organisms rather than molecules that we seem to part company with mechanism.

At this end of the scale, then, our actions are found to depend on the vast mass of cellular material which makes up the nervous system, receiving signals about the outside world from the sense organs and sending out signals to the muscles to produce the complex movements of intelligent behaviour. The nervous signals can be recorded and analysed because they are revealed by brief electrical effects, and we are rapidly gaining a fairly clear picture of the energy transformations which make them possible (and incidentally we should never have gone so far if there had been no radioactive sodium and potassium for tracing ionic movements).

The sensory inflow brings information about the events taking place outside us and progress reports to show how successfully we are dealing with them; signals from the muscles are needed to adjust the simplest movements and we are handicapped if we cannot hear what we are saying and cannot watch our step. But the great central mass of nerve cells has to fabricate a radically different pattern of messages to send out to the muscles and it is a pattern which depends on past as well as present information, on what happened to us a year ago as well as on what is happening now. Unfortunately, it is a great deal easier to study the immediate reactions of the nervous system than the more persistent changes which alter its habits and give us our memories. We know next to nothing about the plasticity which is the most important feature of the brain and that is the next hurdle for the biophysicists and biochemists.

But we do know that the cells of the brain do not behave as passive agents for conducting and combining the signals that reach them. As long as we are awake many of them are in continuous rhythmic activity. The system has its own reserves of energy and is unstable; at all events, it is so constituted that a slight disturbance of equilibrium will start up a cycle of discharge and recovery repeated many times a second and extended through much of its substance. It is no great surprise to find that we are driven to our daily activity by a cell system of this kind with energy to be dissipated; but we are now learning something about the interplay of the different parts of the system. It is found, for example, that a relatively small collection of cells at the base of the brain has a profound effect on the general level of activity, so that we are aroused when it is stimulated and fall into coma if it is injured. We can see too how the chief focus of disturbance shifts from one region of the cerebrum to another when we transfer our attention. In fact, we are beginning to trace a closer connexion between what is going on in the different parts of the brain and what we happen to be doing from moment to moment. For what it is worth, we can see a physical reason for our restless lives and our insatiable curiosity.

One may well feel that the most detailed knowledge of brain physiology will never help us much in our efforts to live peaceably; but it would be rash to prophesy. Certainly there are people now who lead more placid, if perhaps less useful lives, because their anxieties have been diminished by leucotomy, an operation on the frontal lobes of the brain; and long before the advent of leucotomy we had become accustomed to adjusting the activity of our nervous system by chemical agents. Tea and coffee, alcohol and tobacco are the stimulants and sedatives of the pre-scientific age and now, to quote the preacher, there is no end to the works of the apothecary, and we seem to be much less afraid of using the confections he gives us to take away our pains.

Only the writers of science fiction would suggest a future in which the problems of civilization will be dealt with by tampering with the brains of some or all of mankind. It will help us a little to settle our differences if we have the means of ensuring a clear head and an even temper after a long journey and a resetting of the daily rhythm; but clearly we must look beyond physiology for an adequate picture of the human brain in action. Though it should start at the molecular or the cellular level, the evidence for it must include the activities of the finished product. We must find out what human behaviour is like before we try to explain how it is produced.

We do know, of course, an immense deal about human behaviour, from our own experience and from the accumulated wisdom of the past; but it is only in recent times that we have tried to check our knowledge by the methods of natural science. The development of physical science dates from the time when direct observation and experiment were accepted as better guides than the principles which had seemed self-evident to the philosophers and the schoolmen. They were wise enough, but it was found that they could be mistaken. So now we can look to the many branches of social science to make a dispassionate study of what actually happens in our society without regard to what might be expected to happen if we are to believe all we have been taught.

The picture of human behaviour which the social scientist has to draw is of a system in which the units are men and women rather than cells or molecules. It is true that one man behaves very differently from another—it is part of our political creed that they must be allowed, within limits, to differ as much as they like. But, although we can insist that the units are not all alike, the general principles which determine their behaviour ought to stand out when we deal with millions rather than individuals.

There is, in fact, one branch of social science which can adopt this plan without difficulty. This is the science of economics, which considers only the human activities of producing and consuming, and studies the way in which these activities are to be balanced. When the balance is lost, credit and currencies fail and we may blame the economists for the plight we are in; but the status of their science is unquestioned, and no one would dream of saying that our complex civilization could have done as well without them.

It must be admitted, however, that the strength of economic theories rests very largely on the fact that they can be worked out with very little regard to human nature. Men must be assumed to be capable of trading with one another and they must have a variety of skills and needs and possessions; but that is all, or nearly all, that the economist has to consider. Few of the many branches of social science can proceed on such a simple basis, and it is because of this that the subject as a whole has still to win full recognition in Britain where the science of economics is so firmly established.

Theories describing or explaining other kinds of social activity are nothing new, they existed long before the theories of economics; but the economists have had the figures to check their conclusions and until recently the sociologists have had little but their own philosophy and their own reading of history. Even Durkheim, who broke away from the philosophic tradition, could only point the way to a truly objective study of human society. Now the position is quite different. A century and a half ago it had only just been decided that the population of Britain was on the increase. Many had thought that might be so, but there were no figures to show whether they were right or wrong. Now there are all the modern techniques for fact finding, the questionnaires, the punched cards, the sorting machines and the statistical methods. It is far easier now to deal with large groups, and the psychologists have far more knowledge of the irrational factors which can sway the smaller groups as well as the family and the individual. The stage seems to be set for the new development, and it might well be the most important scientific development of this century. Why are we still so reluctant to think well of it?

The answer, I suppose, is that we are not yet convinced that the kind of observations that the social scientist can make will be sufficiently objective and sufficiently precise. Those of us who work in laboratories have a far easier task in selecting what we should observe, yet we know how difficult it is for us to select and observe fairly. We have to school ourselves not to reject the exceptional result as worthless when it does not fit a cherished theory: we have to be continually aware of our own fallibility even though we have all the figures and controls to keep us straight. We are loth to believe that the social scientists are more open-minded than we are, and the material they have to deal with seems to need an almost superhuman open-mindedness combined with an almost superhuman power of selection, of seeing the wood as well as the trees in it. We feel that we should be lost in such a wood where everyone must feel the bias of his own upbringing and social ties, where there is so much that cannot be measured and may or may not be relevant and where there is rarely an opportunity of checking the conclusions by experiment.

Our distrust is probably intensified by the layman's tendency to speak of experiments in the social field as though they were comparable with the experiments which obey all the exacting rules of the laboratory. There we can at least hope to proceed by changing one factor at a time. The social scientist would be the last to cherish any such hope: his whole training warns him of the complexity of any situation where human beings are involved. But many people seem to think that if something in the social field is done in a new and usually more expensive way we have only to call it an experiment to justify the conclusions we wish to draw. Certainly we must try new methods and hope to find out why they succeed or fail; but although a new way to check juvenile delinquency or develop a housing estate may give the most favourable results, it is very seldom an experiment from which one can infer the precise factors that have made for its success. A change in the birth-rate, a wet summer or a newspaper campaign are the kind of disturbing element which would be too obvious to mention were it not that everyone who has worked in a laboratory must be aware of having overlooked disturbing factors which should have been just as obvious. We were lucky if our control experiments saved us from exposing our folly; but controls are far easier in the laboratory than in the world outside.

This is a minor grudge. If we harbour it we shall be visiting the sins of the enthusiast on the very people who exist to keep them in check, and we must surely welcome any new branch of study which tries to substitute the methods of natural science for unchecked speculation. It is very easy for us to forget our own rules when we allow our feelings to take charge, to say that a result was too obvious to be worth the proof if we happen to like it, and if we dislike it to say that statistics can be made to prove anything. Perhaps we have forgotten how much we distrusted some new development near our own field of science because it was unfamiliar and because we thought its backers claimed too much for it. We ought to remember that the now flourishing science of biochemistry was once distrusted by chemists as well as physiologists. It is human nature for the guild of natural scientists to delay admitting a new member until he has paid his dues and satisfied the examiners of his competence in the craft.

At present there are many kinds of investigation grouped under the umbrella of social science: the groups seem to have little in common and few of them can put their results into figures; but I think all of us, scientists and laymen alike, are becoming more aware of the value of social investigation and of the degree of certainty it can bring. We may have distrusted the army psychologists who classed us by our aptitudes, we may have read the Kinsey report from unscientific motives and we may continue to allow the accident-prone to drive their motor-cars. We can see none the less that there are facts to be found out about our usefulness in society, about our relations to one another and about the risks we take. We can see too that the search for these facts can be conducted on reasonably scientific lines. It is too early to be cautious in spending money on large-scale investigations. They are bound to be costly, and those of the social scientist deserve not only the support of national and international funds. There is this kind of support for the subject already; but it is too important a plant to be left in the hot-house atmosphere of research institutes and Unesco teams. It deserves to be in full contact with all the conservative and academic people in universities, the lawyers and historians as well as the economists, biologists and statisticians. There must be more social scientists in our universities so that the rising generation can see what they are like.

I have put in this plea for a subject about which I know so little because it seems to be developing more rapidly in other countries, particularly in the United States. We are handicapped, no doubt, by smaller resources and perhaps by the remains of a national temperament which has made us prefer to work by ourselves and not as members of a large team. We ought not to expect too much. Social scientists, like economists, may be able to foretell the consequences which are likely to follow in a particular situation; but the statesman who goes to consult them may come away with little to comfort him and may turn to the quack doctor in the next street. We may find out a great deal about the tensions which lead to war without seeing the way to keep ourselves clear of it.

But human beings, when we consider them as material for the biologist, are not to be thought of as incapable of improvement. Other kinds of animal have been found to possess unexpected power of communicating with one another; but we are the one kind endowed with a brain which gives us the power of communicating by putting our impressions into words and appreciating the meaning of the words we hear. Speech would be little use to us unless we could remember what it means; but memory, the ability to learn, is a property of the simplest kinds of nervous system. We alone possess a nervous system which gives us the power to order our ideas in words. We alone have this way of thought which allows us to compare a new problem with an old one.

With this unique equipment for thinking and communicating we can form our habits not only from what happens to us personally but from what happens to our fellows and from what has happened to countless generations in the past; and although the storage capacity of a single human brain is limited, we have learnt to make permanent records of what has occurred, in visible symbols, so that what cannot be remembered can be found in a book. In this scientific era our store of knowledge is growing so fast that we shall soon need new ways to keep it available. Books have done duty for a thousand years and we should be sorry to lose them; but we can change our habits rapidly and it is already old-fashioned to write a letter with a pen.

This increasing background of experience has meant that we are constantly acquiring new habits and new ways of thought. It does not take us very long to see the way round old quarrels. Darwin and Freud no longer trouble us. We are no doubt born with brains like those of our remote ancestors and when we are grown up we have no more native intelligence than they had; but our brains must have been so modified by what we have learnt that they are physically and chemically different, better adapted for the complex social life of our time. We have more knowledge at our disposal. If all goes well with our training, the brains we have ought to be more civilized than those of our fathers and those of the next generation more civilized than ours.

I have claimed that the scientific investigation of mankind can help the process of civilization by finding the weak points in our equipment and suggesting remedies; but these scientific activities will play only a limited part in the development of human society in the scientific age. The power we have acquired over the forces of Nature has made it possible to increase our mental training as well as our standard of comfort. Of the two or three thousand million people in the world, perhaps not more than five million are receiving a full university training, though no doubt more are trained in a narrow technology. Yet the number has risen steeply in spite of wars, perhaps even because of them, and it continues to rise. In the United Kingdom we have 85,000 students at our universities, about 1 in 30 of the whole age-group, and that may be all we should contemplate with our present system. A few years ago, however, it was only 1 in 60, and there must be many parts of the world where the university, as we know it, is only now beginning to play its part in civilizing the most intelligent citizens. This could never have happened without all the scientific inventions which have been blamed for our troubles, the improved transport, the cheap printing, the electricity and the internal combustion engine. And a university training would have been far less civilizing if it had never left the old authoritarian pattern which roused Huxley to speak in Oxford nearly one hundred years ago.

University students, however intelligent, are not usually considered to be the most peaceful members of the community. They have been more welcome in small country towns than in the capitals where they can join revolts against the government of the day, and they tend wherever they are to be critical of those in authority. Long may students remain so. If they were not, if they believed all they read in an officially inspired press, or even what they were taught by unrestrained professors of the greatest integrity, there would be little chance of their learning how to use their knowledge for solving the new problems of our time. The plodding methods of the laboratory and the card index must be there to check their enthusiasm and to show them how the problems have come about. Even if they get no help from that, it is something to know that there are many more people in the world to-day with brains better trained to deal with their environment by learning how its problems have been dealt with in the past.

The British Association is concerned with the advance of natural science. It began when we had little control over the forces of Nature, and we have now so much that we might soon become able to destroy two-thirds of the world by pressing a button. Yet the control which has been achieved by science has made it possible for us to improve our own natures by more education in the arts of civilized life. We may perhaps improve ourselves more rapidly if we can gain more insight into human behaviour. That is something which the Association can encourage; but it is only a small part of what it must do. It must not cease to encourage every kind of scientific inquiry, for it is human nature to inquire, to learn by experience, and to profit by what it finds out.

SUMMARIES OF ADDRESSES OF PRESIDENTS OF SECTIONS

RECENT DEVELOPMENTS IN NUCLEAR PHYSICS

THE post-war development of accelerators for atomic particles has enabled a new high-energy branch of nuclear physics to be developed, the main objective of which is the study of the forces between nucleons and their relation to mesons and the meson fields. This forms the subject of the presidential address to Section A (Mathematics and Physics) by Sir John Cockcroft.

In Britain we have brought into operation within the past year, for the study of this field of physics, a billion-volt proton synchrotron, a 400-million volt cyclotron and a 330-million volt electron synchrotron, while the Harwell cyclotron has produced protons and neutrons of energies up to 180 million volts. In the United States, in addition to machines of these types, proton synchrotrons of 2 and 6 billion volts are now operating.

Experiments on the scattering of protons by protons and protons by neutrons have demonstrated the exchange nature of the nuclear forces. The scattering of protons in succession from carbon and hydrogen targets have shown that protons after scattering have about 80 per cent of their spin axes pointing in one direction, that is, they become polarized. This results in four times as many being scattered to the left as compared to the right from the second target. This demonstrates another characteristic of nuclear forces—the very strong interaction between the spin of the nucleon and its orbital motion—which produces a non-central force.

The high-energy collision of nucleons produce π-mesons at nuclear energies greater than 200 million volts. At energies of a billion volts pairs of heavier mesons have been created. One of them is the excited proton first discovered by Rochester and Butler, originally called the V^0 meson. The other is a θ^0 meson, which decays into two π-mesons.

These and other mesons are very closely connected with nuclear forces. In nucleon collisions of medium energy, momentum is transferred through the intermediary of the 'meson cloud' associated with a nucleon. When the collisions are energetic enough, the π-mesons materialize, live for a hundred-millionth of a second and decay. In still closer encounters the heavy meson must play a similar part in nuclear forces, giving rise to shorter-range components of the force.

Mesons are now produced in such large numbers by the accelerators that they can be used for experiments on the properties of the meson. Thus the π-meson has been shown to have zero spin—like an alpha-particle or light quantum. It can form a compound nucleus with a nucleon of a very high degree of excitation. It can also form mesic atoms in which the meson plays a similar part to an electron in the atom, and mesic X-rays are produced in orbital transitions.

The address concludes with a reference to the dangers and peaceful potentialities of these powerful nuclear forces.

NEW IDEAS IN CHEMISTRY

SIR JOHN LENNARD-JONES, president of Section B (Chemistry), remarks in his presidential address to that Section that when the British Association last met in Oxford in 1926 physicists pictured electrons in atoms as rotating in orbits around a central nucleus like a solar system. Though this view had great success in clarifying the behaviour of atoms under the influence of light, and in providing a theoretical basis for the periodic table of elements, it had little influence on chemistry, for it did not prove possible to extend the mode of description to molecules. It was the wave theory of matter which opened the way. This provided a novel way of describing the states of electrons in atoms and molecules and a new technique for calculating their stationary states.

In the new theory two ideas were found to have an important place. The first one was that electrons are indistinguishable from one another, so that an interchange of any two does not produce an observable change. The second one was that electrons in atoms and molecules obey strictly the rule that no two take the same role at the same time. Electrons are said to have the 'property of exclusion'. No theoretical proof has been given of this—it is injected into current theories as a working rule and is justified only by its success in predicting the properties of matter.

These two ideas, together with the wave description of electrons, have proved of great importance in explaining the properties of molecules; in fact, it may be said that a unification of atomic physics and chemistry has thus been brought about. The property of exclusion appears to be more powerful than the forces of repulsion or attraction such as exist between electrical charges of like or unlike kind. These latter are of short range and cease to be effective beyond lengths of atomic dimensions; but the 'awareness' which one electron seems to have of another of the same kind of spin seems to extend throughout a molecule, however large it may be. Electrons can thus influence each other over distances many times greater than the sizes of the atoms which a molecule may contain.

The property of exclusion implies that electrons of the same spin avoid each other as though there were a powerful force of repulsion between them. This plays a vital part in fixing the shapes of molecules and, in particular, in producing the directed valencies of carbon. The occurrence of 'lone pairs' of electrons and the asymmetric distribution of charge in molecules can be traced back to the same property. Thus this seems to be the primary cause of electron-rich regions and the agent impelling chemical reactions to go.

One of the most interesting and profitable applications of the new ideas has been to the structure of conjugated molecules. Many of their characteristic properties, such as alternating polarity and the shifts of electrons under the influence of substituents, can now be understood in principle in terms of the same concepts used for saturated molecules.

THE RELATIONSHIP OF PALÆONTOLOGY TO STRATIGRAPHY

In his presidential address to Section C (Geology), Dr. C. J. Stubblefield points out that Oxford is a shrine of British palæontology, for from Oxford came the first printed illustrations of British fossils. These appeared in the "Natural History of Oxfordshire", published in 1677, from the work of the first curator of the Ashmolean Museum, Robert Plot. Oxfordshire has other claims for pilgrimage. It contains the birthplace of William Smith; a man whose discovery, that the fossils contained in rocks could be the means of identifying strata, gave a new approach to stratigraphy. Furthermore, the richly fossiliferous Jurassic rocks of which the county is composed have here and elsewhere, by their fossils, provided the key to many basic principles of stratigraphy.

The stratigrapher produces geological maps showing the identification and disposition of the strata in available areas; he describes the geology of the earth's crust. The palæontologist works to ensure accurately determined fossils, with knowledge of their conditions of life, structure, relationships and distribution.

At the time of William Smith's discovery, palæontology was very young; but it was nurtured by three distinguished French biologists, Lamarck, Cuvier and Brongniart. The first two noticed in mapping and tracing upwards the rock succession in the Paris basin that the fossil Mollusca became progressively more like living forms; this observation eventually became perpetuated in the formational names Eocene, Oligocene, Miocene and Pliocene. On a broader basis the changing pattern of life revealed by what is now known to be a quarter or less of the history of the earth's crust is also expressed in J. Phillips's terms Palæozoic, Mesozoic and Cainozoic.

The most striking aspect of the application of palæontology to stratigraphy has been in the classification of the stratal column into successively smaller divisions and in correlating rocks found in different parts of the world.

Palæontology, coupled with an appreciation of lithological changes in contemporaneous deposits, played a prominent part in the establishment of the Devonian or Old Red Sandstone System; in the founding of the Ordovician System the faunas were also an important consideration. Stratal divisions known as stages were formulated by d'Orbigny entirely from palæontological studies, and, in revised and extended form, are useful standards of comparison for regional correlation particularly when considered as unit sequences of zones, that is, of rocks containing successive assemblages of fossils. Such sequences of zones have also helped stratigraphers to find evidence of stratal gaps, and of folding and faulting.

While a geological map is the published outcome of a particular local geological study, in Britain it is now regrettably rare to find, in the accompanying account, pictures of the fossils on which critical age determinations are based. On the other hand, the typical large-scale geological map is required to show the distribution of the different lithological units for several purposes, some non-geological. Though palæontology is used for ensuring accuracy in the local correlations, the mapped divisions should not be too subjectively palæontological. Nevertheless, when such maps are combined for reduction to smaller scales, palæontological data are appreciated as being vital for regional correlation of the rock units.

ARCHAEOPTERYX AND EVOLUTION

In his presidential address to Section D (Zoology), Sir Gavin de Beer states that the specimen of *Archaeopteryx* preserved in the British Museum (Natural History) has been subjected to a complete re-investigation with the help of modern methods. Making use of the fact that fossil bone shows fluorescence under ultra-violet light whereas the matrix does not, the sternum has been discovered and its bony nature confirmed by X-rays. It is flat and accords with all the other features of the fossil to show that in life it was incapable of active flapping flight but glided from branch to branch of trees. The endocranial cast of the brain has been studied, and Dr. Tilly Edinger's surmises have been confirmed. The cerebral hemispheres were smooth, elongated, and narrow. The cerebellum was small and situated behind the mid-brain, instead of overlapping it from behind and pressing it down to a more ventral level as in modern birds. For the purposes of its limited powers of flight *Archaeopteryx* did not require a high degree of cerebellar co-ordination. Portions of additional vertebræ have been found, confirming that the articulation between their centra was simple.

It has long been realized that *Archaeopteryx* presents a beautifully intermediate condition between reptiles and birds. In principle, an organism intermediate between two groups might be intermediate in structure in all or many of its parts; or it might be composed of a number of structures completely characteristic of one group, a number of other structures equally characteristic of the other group, and few or no features intermediate in structure at all. It is quite clear that the transition from reptiles to birds exemplified by *Archaeopteryx* conforms to the latter alternative, for *Archaeopteryx* is a mosaic of typical reptilian and typical avine characters. The reptilian characters are: the long tail of twenty free vertebræ, the simple articulation between the vertebral centra, the short sacrum involving six vertebræ, the separate metacarpal bones and the presence of claws on all digits of the hand, the separate metatarsal bones, the simple ribs and gastralia, the simple brain with elongated narrow cerebral hemispheres and small cerebellum behind the optic lobes. The avine characters of *Archaeopteryx* are: the feathers identical in structure with those of modern birds, the arrangement of the feathers on the arm identical with that in modern birds, the fusion of the clavicles to form the furcula, the backwardly projecting pubes, and the opposable hallux of the foot.

The transition from reptiles to birds is therefore regarded as providing an example of a mode of evolution termed mosaic evolution, and the question arises whether this mode is also found in the transitions between other classes of vertebrates. The structure of the Ichthyostegalia suggests that this was in fact the case in the evolution of amphibia from fish, and *Seymouria* provides evidence of the same thing in the evolution of reptiles from amphibia. The transition from reptiles to mammals is more complicated to follow, largely because the conventional definition of mammals as vertebrates possessing hair and a squamosal-dentary articulation of the jaws has led to the retention within the reptilian class of most of the stages of the conversion of reptiles into mammals. Nevertheless, it is extremely probable from the evidence furnished by the ictidosaurs and by the monotremes that the mosaic mode of evolution applied there also.

The emergence of each of the classes of living vertebrates has been characterized by the acquisition of key-characters which have enabled the organisms to become adapted to and radiate widely in an ecological medium previously denied to them: land-and-water, dry land, air. The break-through into the new medium has been made possible by a change in a very small number of pieces of the mosaic, the other pieces remaining as they were for a considerable time. The significance and wide application of the mosaic mode of evolution was clearly recognized by D. M. S. Watson, who provided irrefutable evidence from *Seymouria* in its support, for which reason it is proposed to refer to it as Watson's Principle.

THE COAST AND THE GEOGRAPHER

IN his presidential address to Section E (Geography), Prof. J. A. Steers points out that the geographer has many, but by no means exclusive, interests in the coast. The borderline between land and sea at any one moment of time may seem relatively stable. But changes, both vertical and horizontal, are constantly going on, and those due to erosion and deposition are clearly noticeable in the course of a few years—and sometimes much less. Vertical changes are measurable locally in decades, and in the period since the beginning of the Ice Age they have been profound.

Vegetation, especially on low coasts, can bring about impressive changes in even a few years, and there is much room for experimental work in this field.

The still wider question of the primary origin of coasts is geological rather than geographical; but the study of off-shore contours and evidence of recent movements of a vertical nature, in so far as they affect an 'original' coastline, are of great geographical interest. Apart from physiographical implications, there are many others which concern the geographer. Not least among these is the general picture of the use of the coast by man—ports, industry, dwellings, holidays, etc. The details of planning are scarcely his direct concern; but in presenting an overall view the geographer by his training in the appreciation of regions ought to be able to contribute something of importance.

The geographer can make valuable observations on the factors—waves, winds, tides, etc.—acting on a coast, and since he is probably working on a problem from a purely personal and scientific point of view he is not likely to be concerned only with short-term factors. Hence his contribution to morphology and other aspects of the coast is of use to students in general as well as to engineers.

But when all is said and done, the understanding of the coast is by no means the province of any one group of workers. The more there can be active and friendly collaboration between engineers, geologists, ecologists, and geographers, the better. To achieve this end, there is no need for any very precise organization.

Geographers have great scope for their own particular interests, and the historian or historical geographer has much to give in this respect. There are many examples in Great Britain, and especially around the Mediterranean and North Seas, where the changes affecting ports and harbours and the growth of deltas need the double approach that a geographer trained in both the historical and physical branches of his subject can make. A great deal of the literature at present dealing with such matters minimizes or even overlooks the significance of this double approach. Moreover, there may well be a practical lesson to be learned from such studies. None, for example, would ignore the long history of change wrought by storm and waves along the East Anglian coast in considering new defence or harbour works.

In tropical waters, too, there is plenty of work for the geographer. Much of the significance of coral reefs, of the sand formations resting in them, and of beach-rock formation has yet to be learned. In this connexion, too, co-operation with a biologist will be more than worth while.

Many of the problems with which the geographer is concerned on a coast may be partly investigated in laboratories in which models of the coast are built. These, however, are expensive and not likely to be made unless valuable land or property is affected. Nevertheless, whenever or wherever it is possible for laboratory experiments to be made, full advantage should be taken of them.

THE CHANGING STRUCTURE OF THE BRITISH ECONOMY

THE development of an economy is a process of adjustment to changing technology and changing quantities and distributions of materials and skills. The economic structure at any moment reflects only imperfectly the needs of that moment, since structure changes slowly, and only in periods of less rapid change are the ideal and actual structures likely to be similar. The main elements of structure are the patterns of employment and activity, of export and import, and of consumption.

In his presidential address to Section F (Economics), Prof. E. A. G. Robinson points out that these patterns have changed greatly in the United Kingdom during the past two and a half centuries, when their measurement has been reasonably possible. When Gregory King first estimated many of the relevant statistics in 1688, the population of the United Kingdom was about 7·4 millions. Its retained imports were equal to about 5¼ per cent of national income; exports were primarily manufactures of indigenous materials; about two-thirds of all man-power was engaged in agriculture, and England was still a net exporter of agricultural produce.

By 1820, the proportion of employment in agriculture had fallen to about 35 per cent; the import ratio had risen to about 12 per cent; manufactures formed about 90 per cent of all exports, and textile manufactures 67 per cent; coal formed about 1 per cent of total exports. Raw material imports were now about 60 per cent of retained imports, of which textile materials accounted for about 24 per cent.

This process of specialization, of dependence on imported materials and on exports of textiles took a more extreme form as the century went on. By 1870 the import ratio had risen to about 28 per cent (its peak was about 33 per cent in the 1880's). The proportion of retained imports represented by food had risen to 35 per cent (of which grain was 9 per cent); but we probably provided three-quarters of our food from home agriculture. Textile exports were still the main source of payment for imports, representing 56 per cent of the whole; exports of metals and metal manufactures were beginning to grow and now formed 21 per cent of the whole.

By 1913 the import ratio was back to 28 per cent; with growing population (it was now about six times that of 1688) we had become dependent to the extent of about 55 per cent of our food consumption on imported food, which now formed about 40 per cent of retained imports. At the same time, we were much more dependent on imported materials; home supplies of wool had covered 50 per cent of consumption in 1860; they covered only 16 per cent by 1913. Textile exports were now 34 per cent of total exports; metal and engineering exports had risen to 27 per cent.

Some of these trends continued through the inter-war years. But the import ratio declined, and by 1937 was 21 per cent, partly as a result of lower import prices, but chiefly as a result of balance-of-payments difficulties. The reliance on imported food increased and imports probably provided 65 per cent of food consumption in the years before 1939; but by 1951 this had been reduced to about 50 per cent. Agriculture, which had given employment to 14 per cent of the working population of Britain in 1870 and 8 per cent in 1913, was now down to about 5¼ per cent. Textile exports declined greatly; by 1937 they were 24 per cent of the whole, and by 1951 only 19 per cent; the share of metals and engineering exports rose to 35 per cent in 1937 and to 49 per cent in 1951.

It is interesting to contrast the structures of the United Kingdom and of Western Germany. They have almost identical populations, very similar areas, but very different structures. In 1953 the United Kingdom import ratio was 26 per cent, that of Western Germany about 16 per cent. Western Germany maintains an industrial production about two-thirds as great as that of the United Kingdom on raw material imports about one-third as great. It is dependent on imports for only about one-fifth of its food consumption. Each country has much to learn from the other.

It may be difficult for the United Kingdom to continue to find markets for exports on a scale sufficient to maintain its existing import ratio. The high degree of specialization of the second half of the nineteenth century was based on a degree of technical leadership which we cannot hope to recover, and on obstacles to the dissemination of scientific and technical knowledge which, once they have disappeared, cannot be recreated. There is probably less technical advantage now from a high degree of specialization and exchange. The United Kingdom's advantage lay also in the fact that everywhere the terms of trade between primary production and manufacture were very favourable to the latter; we were increasing our imports of primary products from countries, particularly in North America, where there were very considerable gains from moving out of primary production. Circumstances may thus demand considerable change in the United Kingdom's structure. But if there is reluctance to modify the structure, the consequences may be balance-of-payments difficulties which can only be remedied by measures that diminish imports by diminishing activity and employment.

EFFECTS OF NEW MATERIALS ON ENGINEERING PROGRESS

THE dependence of engineering progress on improvements in the existing materials of construction and on the discovery and economic development of new ones forms the subject of Dr. Willis Jackson's presidential address to Section G (Engineering).

Choosing his examples mainly from electrical engineering, he deals first with the insulation of high-voltage power cables and submarine cables. In the former, impregnated lapped paper, introduced by Ferranti in 1898, remains the only form of dielectric structure which can be seriously considered for the highest transmission voltages, notwithstanding the wide range of new synthetic materials which have since become available. From some points of view this may appear to suggest too conservative an attitude on the part of the cable manufacturers; but it can be more properly regarded as a tribute to their ingenuity in overcoming the limitations of the constituent materials, paper and oil, and in introducing new techniques of construction, which have proved adequate to meet the increasingly severe operating requirements. In submarine cables, on the other hand, the previously well-established gutta percha insulation has now been displaced by polyethylene (polythene). The material emerged from the research stage just in time to play a vital part in our early war-time radar installations as the dielectric of the high-frequency cables used for interconnecting the transmitter and aerial systems. Stocks of polyethylene-insulated submarine cables were built up later during the War in preparation for the invasion of the Continent, and the trans-Atlantic telephone cable incorporating submerged repeaters, soon to be embarked upon, is to be made of the same material.

Speaking next of the effect which the development of the low-carbon silicon steels has had on the performance of power transformers, Dr. Willis Jackson explains how the marked crystal orientation which can be produced in silicon steel sheet by appropriate cold-rolling and annealing treatments has made it possible to take advantage of the directional properties exhibited by single crystals of ferromagnetic materials. A more spectacular advance has occurred in magnetic materials for telecommunication applications arising from the introduction of the nickel–iron alloys and of powder-core technique and, more recently, from the war-time development of the ferrites, a range of non-conducting materials derived by replacing one of the iron atoms of Fe_3O_4 by atoms of other elements such as nickel, zinc, manganese, etc.

As an illustration of the way in which the discovery, and recognition of the potentialities, of some special property of a material may lead to the development of a new engineering technique, Dr. Willis Jackson describes the evolution of the germanium crystal triode, the transistor, an amplifying device which can perform many of the functions of the thermionic triode valve with the advantages over it of being simpler in construction, much smaller in size and not requiring a heated electrode as its source of charge carriers. Many difficulties have had to be overcome in the extraction and extreme purification of germanium; but the new device has a wide sphere of application in computers, guided missiles and telecommunications equipment generally.

The conversion of the nuclear energy of uranium into electrical energy affords another example of this type of development. The practicability of this conversion is dependent on the use of other materials also possessing special properties, though of a different kind, which have led to the rapid rise to engineering importance of such materials as heavy water, liquid sodium and zirconium.

Finally, after referring to the new ceramic materials based on barium titanate, to the emergence of titanium as a structural material and to the recently discovered beneficial effects on the physical properties of certain plastics which result from their irradiation by high-energy particles, Dr. Willis Jackson emphasizes the growing interdependence of progress in chemistry, physics, metallurgy and engineering.

ARCHÆOLOGY IN THE BRITISH COLONIES

SIR MORTIMER WHEELER'S address to Section H (Archæology) is entitled "Colonial Archæology" and is a plea for the urgent need to safeguard cultural and, in particular, historical and archæological evidence in and relating to British Colonial territories. Sir Mortimer is especially concerned with territories of British East Africa—Zanzibar, Kenya, Uganda and Tanganyika—but he also gives evidence showing that the position is bad in the Somaliland Protectorate and Aden and scarcely less unsatisfactory in West Africa, so that by extrapolation it can be surmised that the conservation of cultural treasures is sadly neglected to a greater or lesser degree throughout all the Colonial territories of the British Commonwealth.

The examples quoted from East Africa make indeed a sorry tale. Sir Mortimer gives chapter and verse of priceless buildings, many of them mosques of unique features, that have been pillaged for one reason or another, often quite recently, and in some cases they have even been deliberately destroyed by public works departments to make way for new roads or to supply building materials. The situation is chaotic in that each Colony has its own regulations with regard to conservation, and even where the laws are comprehensive and sensibly framed, their interpretation or execution is often left to officials with many other pressing duties or to persons with little or no interest in the matter. Now and then the story is relieved by examples of excellent (and timely) work; but these bright spots in the pervading gloom are all too often due to the fortuitous hand of some exceptionally enlightened person who struggles alone amidst apathy.

In July last year a widely attended Conference on African History was held in London under the chairmanship of Prof. C. H. Philips, of the London School of Oriental and African Studies, and from the three-day discussion six resolutions were drafted: the outlines of African history could be reconstructed by the co-operation of historians and archæologists; this implies the adequate preservation of ancient and historical sites, monuments and documents, and the development of museums and public record offices; immediate government action and control is therefore needed in the various territories; ultimately departments of antiquities will need to be set up to plan field-work and publish results; record offices, with archivists to run them, will need to be improved or, in some cases, to be created; and as an immediate step, a school of history and archæology in East Africa needs to be established on the lines of the British schools in Rome, Athens and Ankara. These resolutions have been sympathetically received by the Colonial Office, which is ready to be advised on these points by a committee set up by the British Academy; the committee is at present discussing the matter.

Sir Mortimer is of the opinion that finance is not the prime hindrance. He believes that the foremost need is to introduce an adequate antiquities law for each territory. Then the interpretation of the law must not be left solely to the governors and district commissioners; they must be guided by experts, who will in fact be the staff of a territorial archæological department. Such a department needs as an absolute minimum a director, one or more assistant inspectors, normally of local origin, a skilled local foreman, and a museum-cum-store in the charge of a trained curator. A skeleton staff of this pattern will not be over-expensive, for already many territories are bearing certain charges—for example, museums—often in an ill-organized way. But fundamentally the need is for an awakened appreciation by the general public, particularly those in the territories themselves, of the high priority of these problems. The African must be acclimatized to cultural values as much as to political and social evolution. What Lord Curzon did for India and what the French are already doing in their African Empire must be repeated in the British African territories. Though his address deals for the most part with a sorry record of shortcomings, Sir Mortimer Wheeler believes that the present British Colonial administration is concerned about the situation, and he looks forward to the time when good intentions will be translated into actual deeds.

THE RELIEF OF PAIN

PROF. A. D. MACDONALD, in his presidential address to Section I (Physiology), remarks that the problems of pain were discussed by the Section at St. Andrews during the final day of the 1939 meeting of the British Association. At that time the relief of pain by drugs was largely limited to opiates, though the late Dr. T. F. Todd discussed the value of intrathecal injections of alcohol in the terminal stages of malignant disease of the pelvis. His aim was to block sensation, if possible without destroying the motor pathways.

Since then, because of the many drawbacks to morphine, much research has been devoted to the modification of the morphine molecule and to synthetic substitutes in the hope of reducing the disadvantages of morphine. Much ingenuity has been directed to methods of comparative assay of analgesics; but their study in experimental animals is difficult and probably only of value as a screening measure, to be followed by tests on man in both laboratory and hospital. Many compounds have failed to fulfil their initial promises.

Perhaps the most interesting of the morphine derivatives of recent introduction are lævorphan and dextromethorphan, and of the morphine substitutes pethidine and methadone, both of which may be regarded as stepping-stones to long series of related compounds. As a rule, when a derivative is found to be more powerful as an analgesic, it is more toxic and has other grave disadvantages. Pethidine itself has the support of the Medical Research Council

Committee on Analgesia for Labour and is widely used in combination with nitrous oxide or, better, trichloroethylene. The dithienylbutenylamines are more active than pethidine but inferior to morphine. Methadone is in the morphine class as an analgesic, but is less effective in reducing anxiety and promoting sleep.

Potent analgesics are potential drugs of addiction and are, like morphine, carefully controlled by law. Tolerance and dependence may develop even with pethidine, and the need for a reliable analgesic which is not addiction-producing has still to be met. As a laboratory-worker Prof. Macdonald was fortunate in having, to follow him, Dr. P. O. Wolff, of the World Health Organization, Geneva, to discuss some of the problems of addiction, and Mr. J. Pennybacker, of Oxford, to deal with some of the contributions of neurosurgery to the relief of pain.

RECENT STUDIES IN THE PSYCHOLOGY OF THINKING

THERE is a growing sense among psychologists that the psychology of thinking is not only one of the most important areas of psychology both theoretically and practically, but also that it is an area that can be profitably investigated by scientific methods. Thinking is a complex activity rendered possible only as the result of a long period of evolutionary and individual development, and it depends on the co-operation of favourable organic and environmental conditions. The three major aims of the psychologist are: first, to study in detail the development of thinking from its simplest forms to the most highly developed logical and mathematical thinking; secondly, to study the conditions upon which thinking depends; and thirdly, to throw some light upon the general nature of the processes involved in thinking. The purpose of the presidential address by Prof. L. S. Hearnshaw to Section J (Psychology) is to present a sort of interim report on some of the more recent work and speculations of psychologists in the field of normal psychology.

Among this recent work a very high place must be given to the developmental studies of children's thinking carried out by Piaget in Switzerland. Piaget's recent work is not as yet well known in Great Britain. The importance of Piaget's studies is not merely that they constitute by far the most detailed account of children's thinking from the hour of birth to adolescence that has yet been made; it has much more in the comprehensiveness of their scope and their systematic theoretical organization which links the two poles of biology and logic. His studies of the genesis of mathematical and scientific thinking should be of great interest to scientists.

The work of experimental psychologists, though much more fragmentary than that of Piaget, has thrown some light on the subtlety of the personal, emotional and environmental factors that may influence thinking. Though the results of experiments in this field are still meagre in quantity, they indicate the practicability of an experimental approach which may in the course of time place our intuitive art of thought upon firmer foundations.

The tendency of contemporary psychologists is to regard thinking as a high-level skill, derived and built up, therefore, not, as in older views, from special cognitive elements, but compacted, as all skills must be, of both sensory and motor components. Skills are essentially activities, and skills are learned. The gestalt psychologists rightly emphasized organization as an essential feature of all skills, including thinking; but their further contention that this organization is immediate, unlearned, and unanalysable is much less acceptable. In a series of important experiments with monkeys, Harlow has traced the development of apparently immediate insightful behaviour through the establishment of what he terms "learning sets". Insightful behaviour is an end product, the result of a mature skill gradually acquired by experience, and marked increasingly by flexibility, transfer and generalization.

No theory of thinking as yet comes near comprehending the full range of the phenomena we know as thinking. Thinking cannot be equated with problem solving. An adequate theory must embrace every kind of thinking, normal and pathological. Recent studies suggest, however, that the psychology of thinking is no longer an esoteric study, but a branch of psychology which can be objectively studied, and which joins hands not only with better settled areas of psychology, but also with subjects like biology and logic, which lie beyond its own frontiers.

PLANT GROWTH AND PRODUCTION

IN his presidential address to Section K (Botany), Prof. W. H. Pearsall points out that botanists are faced to-day with many developments arising from new and exciting techniques. These have suggested to many that botany is liable to split up into a great number of highly specialized lines of inquiry. On the contrary, these new methods of inquiry should, from various directions, throw new light on the fundamental botanical problems which centre around the organization and growth of plant cells and tissues. Just as growth is the integration of the plant's activities, so the study of growth will serve to integrate inquiries on different aspects of botany.

If the botanist is thus interested in plant growth as a fundamental process, *per se*, the general public is interested in it because it is the means of producing food and raw materials, of which the world is in danger of being starved. It may be useful, therefore, to look on this latter subject somewhat systematically.

Methods of growth analysis devised by F. G. Gregory and his colleagues show that most plants appear to have similar values for their photosynthetical efficiency in growth. The efficiency of a crop thus depends generally more on climatic variations and on the extent and duration of plant-cover than on the nature of the individual plant. This can be illustrated in various ways, particularly by reference to J. D. Ovington's figures for the annual production of dry matter by various types of planted tree. In natural vegetation, too, dry-weight production seems to fall between similar quantitatively definable limits which bear little relation to the type of plant involved, or to some of the obvious ecological factors. Thus, in terms of annual dry-weight yield, waterlogged swamp-soils may be as productive as drained or normal ones.

It appears that very considerable increases in the production of food or raw materials are possible with more continuous crop-cover and improved methods of land-use; but methods of food collection also merit more attention. The use of animals to concentrate proteins is wasteful, especially as the high value of leaf proteins is now established and new methods of isolating and storing them are becoming available. The development of these conventional methods of increasing production may well satisfy human needs for many years.

However, other points of view are now becoming prominent. It is evident that the current methods of agriculture are open to criticism on three theoretical grounds: they absorb only a very small part of the incident sun's energy—usually less than 0·1 per cent; they are subject to all the vagaries of uncontrollable climatic variation; and finally, the yields compare unfavourably with those of modern industrial processes. For these three reasons an unconventional approach to the problems of food production has frequently been suggested, and the possibility of controlled employment of micro-organisms in a photosynthetical unit has been canvassed. A discussion of the use of an alga like *Chlorella* in this connexion reveals the practical difficulties that are involved, though real advances in the future are likely from the use of this type of organism.

What is really being envisaged is the development of controllable systems in which the organism acts as an enzyme complex, such that both rate of reaction and type of product can be strictly determined. The problem is whether a sufficiently high rate of photosynthesis can be maintained to give the very large increase in yields which would be industrially desirable in such a system. Botanists would emphasize the unrealized possibilities for synthesis existing in such autotrophic systems. They will also realize the greatly increased knowledge of cellular organization which must be acquired before such methods become possible.

THE TEACHER IN THE TWENTIETH CENTURY

MR. RONALD GOULD in his presidential address to Section L (Education) remarks that the quality of teachers will always be one of the determinants of the quality of succeeding generations. The characteristics of a teacher of high quality are technical competence; a knowledge of the subject to be taught; the power to communicate knowledge; a broad educational background; and personality (that combination of personal characteristics, difficult to define but easily recognized, which enables him to stimulate and encourage his pupils individually and collectively).

Three conditions, however, must be satisfied if the qualities of the teaching profession are to be improved. First, teachers must realize the need for continuing their education. The training college course should be extended to three years. More adequate attention could then be paid to the theory and practice of education, and higher educational standards achieved. Further, every serving teacher should look to his own education, working out his own philosophy, striving to achieve that maturity of mind which would enable him to sift the wheat from the chaff in current educational thinking and practice. This could be done by organizing more refresher courses, the extension of exchanges with American and Dominion teachers, and the release of experienced teachers from school, for six months or a year, for the purpose of undertaking worthwhile educational investigation. Above all, teachers should read widely and keep abreast of modern thought.

Second, teachers must be assured of considerable freedom in their professional work. Freedom from the fear of arbitrary dismissal is essential: so are civic freedom, freedom from compulsory duties not concerned with the work of the school, and academic freedom. After long and hard struggles, teachers have now attained security of tenure. Civic freedom is not a freedom established by law but has been conceded by local authorities because of constant pressure from teachers. This freedom, however, is still threatened. Freedom from compulsory extraneous duties has but recently been established, since only a short time ago teachers were sometimes appointed to county schools not on the basis of their qualifications as teachers, but because they were prepared to be choir masters, Sunday school superintendents, parish clerks, or to assume some other responsibility in the district. Academic freedom is of enormous importance. Within the limits imposed by law, public opinion and the broad consensus of professional opinion, the teacher should be free to choose both the content of his curriculum and the methods to be used. All these freedoms have been acquired in the past fifty years.

The third condition necessary to establish real quality in the teaching profession is that all concerned with the education system—teachers, local authorities, the Government and parents—should regard themselves as a partnership. There is now real partnership, in spite of some misunderstandings and conflicts as to the speed of advance or the means to be adopted, for all these parties are conscious that they serve the child. This is, however, a recent conception. In the eighteenth century, there were three basic ideas about the provision of popular education: it was a charity, it was a voluntary and not a State effort, and it was under ecclesiastical auspices. Such conditions made partnership with teachers impossible. There was little change even after the establishment of School Boards in 1870. From 1902, however, relationships between the teachers and H.M. inspectors, and between teachers and local authorities, slowly improved. Under the Education Act, 1944, administrative power in education was divided among the Minister of Education, 146 local authorities, hundreds of divisional executives, thousands of managerial and governing bodies and a quarter of a million teachers. Such a dispersal of power was politically sound. Successive Ministers, to their credit, have willingly shared with others powers legally their own, and the establishment of many advisory committees by the Minister is evidence of the voluntary sharing of power and the desire for a real partnership. Parent–teacher co-operation, too, has shown marked improvement.

The future, however, holds some dangerous possibilities—the possible reform of local government and in 1956 the review of the education grant formula. Neither of these should be allowed to affect adversely the freedom of the teacher and existing partnerships.

AGRICULTURE: THE INDUSTRY AND THE SCIENCE

THE art and practice of agriculture advanced very little during the two thousand years prior to 1900, the principal change being the evolution of a system of farming which combined the Saxon plough with the Roman knowledge of agriculture. But, Dr. R. E. Slade points out in his presidential address to Section M (Agriculture), during the past fifty years there have been great changes. The tractor has replaced the horse; the combine harvester is replacing the reaper and binder and the threshing machine. We have improved the fertility of the land by our knowledge of fertilizers and other mineral requirements. We have supplies of phosphates, potash and nitrogen fertilizers. We have insecticides which protect our crops from practically all insects. We can protect our seeds from fungus diseases and we have selective weed killers by which we can destroy the weeds without affecting the crop. We have developed silage and grass-drying for the preservation of summer crops for the winter. We have applied the advances in medicine to veterinary science and we have got control of most of the ills from which animals suffer. We produce only clean milk, and we have increased the yield of our cows by 20 or 30 per cent. We can keep pigs and poultry under labour-saving intensive conditions without getting into trouble through deficiency diseases.

The agricultural industry in Great Britain comes very much under government control. This control of the industry was designed for war conditions and it has lasted until this year. Some industries were decontrolled almost immediately after the end of the Second World War and were able to reorganize for peace-time production when other nations were unable to flood our market with their goods. While agriculture has been under control, the methods of marketing agricultural produce have remained completely stagnant. Now we have neither the organization nor the physical assets to sell our produce in competition with well-organized imports. Organizations are being improvised; but we sadly lack well-equipped abattoirs, cold-storage plants, bacon factories and milk conversion factories as well as organized markets. The annual gross value of the agricultural produce of Britain is now about £1,000,000,000, so farming is one of our largest industries.

An examination of some examples of the introduction of science into the service of the industry indicates that scientific knowledge and inventions are most rapidly adopted when they are introduced to the industry by well-informed salesmen, backed by scientific advisers. The Milk Marketing Board has had a considerable effect on the development of dairying and has been the intermediary for applying science to the industry.

The Agricultural Research Council under the Lord President of the Council spends about £3,000,000 per annum on research. The Agricultural Improvement Council under the Ministry of Agriculture has experimental husbandry farms, and there is also the Agricultural Advisory-Service which covers the country. There are thus three layers each covering all agriculture: (1) research, (2) experimental husbandry, and (3) advisory service. Each layer is in itself doing very fine work and excellently co-ordinated. But there is no vertical drive through the three layers. Perhaps some day the present organization will have added to it vertical as well as horizontal direction, and there will be a freer interchange of personnel between the different layers. Then we may expect to see our scientific discoveries rapidly brought into use on the farms.

PHENOLOGY—THE STUDY OF THE SEASONS

In an introduction to his presidential address to Section X (Assembly of Corresponding Societies), Dr. C. B. Williams compares the young naturalist in the British Isles with one living in the tropics. In Britain there are books, museums and societies, all ready to help and encourage, and Nature is on the whole benign, so that children can be encouraged to study in the fields. In the tropics, Nature is often malignant and there are so many dangerous animals and plants that children have to be taught to fear until they have the knowledge to study. There are also so few books, museums and societies that many possible naturalists lose their enthusiasm from the lack of companionship in their studies.

The study of phenology—or the sequence of biological events in the changing seasons—is an example of a branch of field natural history, covering both animals and plants, in which for many years most of the work in Britain has been done by amateurs. One of the most remarkable examples of continued amateur effort is the series of observations taken in the village of Hevingham in Norfolk of the first date in each spring of the leafing and flowering of certain trees (hawthorn, oak, ash, etc.), the arrival of certain birds (such as the swallow and cuckoo) and the first appearance of some insects. The observations were started in 1736 by Robert Marsham, were continued by him until his death in 1797, and were carried on by his son until 1810. There was then a gap of twenty-five years; but in 1835 the observations were resumed and have been carried on ever since by different members of the same family. The series covers nearly two hundred and twenty years, with only one relatively short break. In the middle of the past century there was a general spread of interest in the subject, and the Royal Meteorological Society formed a Phenological Committee which issued regular annual reports from 1874 until 1947. All the observations were sent in by amateurs scattered over the country, who reached a maximum of more than six hundred in 1931. Unfortunately, interest then waned and in 1947 the Committee gave up this work.

Observations of this type are of great importance for studying the relation of the dates of natural events to changes in weather, climate and geographical position; and the research scientist and the amateur naturalist should co-operate to put the work on a sound basis.

Unfortunately, the analysis of the records is complicated by many accidental sources of error. Some of these can be avoided by greater care, greater regularity of observation, and an increased number of observers scattered widely over the country. Other errors are more difficult to reduce—such as differences in ease of observation between plants and animals, between birds which sing and those that do not, differences due to variation in the abundance of the animal or plant to be observed, and in the ability and experience of observers. For a proper study of the problem events should be selected to cover the whole year round, without so much emphasis—as in the past—on the return of spring.

An appeal is made by Dr. Williams for a better understanding between the research scientist and the amateur, so that each can appreciate the desires and difficulties of the other.

THE NATIONAL INSTITUTE OF AGRICULTURAL BOTANY: ITS PAST, PRESENT AND FUTURE*

By SIR JOHN RUSSELL, O.B.E., F.R.S.

THE National Institute of Agricultural Botany, Cambridge, was founded in 1919 at the time when scientific plant breeding was first being used for the improvement of agricultural crops; its purpose was to test, multiply and popularize new and desirable varieties as they were produced. With it was incorporated the Seed Testing Station that had been founded two years previously. The work has proved so successful that the original staff of four technical officers has now expanded to fifty-three.

The need for the Institute's work to-day is at least as great as ever it has been: Hunter, Engledow and Bell are still producing new varieties of cereals. Others too are active; during the past twelve months the Institute has received fifty-six new varieties of cereals, more than half of which are already approved or recommended in their own countries. It is a great service to our agricultural community to have these thoroughly tested in Cambridge before they are widely taken up by farmers. Moreover, British agriculture is now in a period of some uncertainty. The clear-cut situation of the Second World War, when calories—in practice, wheat and potatoes—and also milk, were our overmastering needs to be achieved at all costs, no longer exists; nor is the immediate post-war problem of saving dollar imports quite so insistent as it was, especially so far as Canada is concerned. Instead, farmers have a general request to produce all they can. But as against this, farmers are conscious of huge surpluses of wheat and other agricultural products piling up unsaleable in the United States, and many of them fear that if they do go all out for increased production they will simply be creating unsaleable surpluses that will be left on their hands. I do not think they are justified, for the surpluses are mainly local and largely confined to North America; the other great producers, the Argentine, Australia and Europe, produce little more than before the War. If and when the United States reduces its acreage of wheat, the surplus will shrink. The European and Mediterranean buyers of wheat are almost certain to increase their imports as their populations increase and their standard of living rises; some of them have already considerably increased their imports of wheat compared with the pre-war days. So also has Egypt, for the very interesting reason that where wheat will grow so will the valuable long-stapled cotton, and in a recent barter with the U.S.S.R. (February 1952) Egypt obtained in exchange for one acre of cotton as much wheat as would have required three or four acres of land to produce. Taking the long view, I see no reason to fear a continued over-production of wheat any more than I fear a coming shortage for those peoples that can afford to buy it.

If there is some anxiety about the future markets for agricultural produce, there need be none about the British farmers' ability to produce. Some of our soils have been cultivated for a thousand years, and some even for double this period; yet they have suffered neither deterioration nor loss by soil erosion, and the yields of crops have steadily increased and, so far as one can judge, are still steadily increasing. The average yield of wheat in Britain before the Second World War was 18 cwt. per acre; it is now 21·5. Barley has gone up from 16·7 cwt. per acre to 20, and oats from 16·3 to 18. Potatoes and sugar beet also show impressive increases. These values are among the highest in the world. But they do not represent anything like what the fields could produce if only we knew all the secrets. Our present average yield of 21·5 cwt. of wheat per acre is, of course, much exceeded by good farmers, who would commonly expect 30–35 cwt. per acre; but these quantities look puny compared with the yields of well over 3 tons per acre recorded in some of the Institute's trials and the 70 cwt. per acre obtained on a commercial farm in East Anglia quite recently. The average yield of potatoes in Britain, 7·4 tons per acre, and the yield expected by good farmers, 10–12 tons per acre, are put in the shade by the 27 tons per acre obtained in Lincolnshire in 1950. We do not know how these big yields are obtained; but they show clearly that we are nowhere near Nature's limits yet, and if we could only let in a little more light we could hope to get such further knowledge as would enable us considerably to increase our yields. Some good teams of scientific workers at Cambridge, Rothamsted, Oxford and elsewhere are striving to learn more about the growth of crops, and if they are left in peace to get on with the job we may reasonably hope for results, though no one can foretell when they may come.

The achievements since pre-war days have been most impressive. Before the War some 30 per cent of the calories being consumed in Britain were produced; this was the equivalent of feeding 14½ million people. By 1950 the production of calories was the equivalent of feeding 20 million people, an increase of roughly 50 per cent in about twelve years—a really astonishing result. In the meantime, the population had increased, and the new production represented 40 per cent of the nation's need for calories; the 30 per cent of pre-war days is now raised to 40 per cent. But the cost has been heavy. To step up from 30 per cent of our requirements to 40 per cent in 1950, the consumption of fertilizers had more than trebled; the number of tractors increased nearly six times; subsidies for farm operations amounted to £24·37 million; expenditure on the agricultural departments—supervision, advice and other activities of ministry officials—rose from the pre-war £8·9 million to £63·7 million, a sevenfold increase; and the cost of producing the food was such that a subsidy of £246 million was needed to enable it to be sold at the prices actually charged. We could, of course, push up this production of 40 per cent of our requirements to 50 per cent, and quite serious people have even claimed 100 per cent; it would be an interesting parlour game to try and calculate the cost. One fact is impressive. The subsidy of £246 million was for the 40 per cent of food that we produced; whereas for the 60 per cent that we imported the subsidy was only £164 million; this looks like 50 per cent more food at 30 per cent less cost. Actually it is not as simple as that, as the foods are not the same. But the fact remains that the same foods cost more to produce in Britain than they do in Denmark or Holland. One of our most urgent problems is to reduce this cost of production. Good farmers have long tried to do it, many of them with conspicuous success: agricultural economists who study farmers' accounts report differences up to 100 per cent in the cost of production of the same article on different farms in the same region. This article is not the place to discuss the reasons for that, but one can emphasize that the use of high-quality seed and of improved varieties is one of the surest and least-expensive ways of reducing costs of production.

---

* Substance of an address given at the annual general meeting of Fellows of the National Institute of Agricultural Botany on July 16.

No country of comparable size stands in need of so wide a range of crop varieties as Great Britain, because no country of comparable size, except perhaps New Zealand, shows so wide a range of soils and climates in such a small space. A horticulturist to whom time and money were no object could probably persuade one and the same variety of a plant to grow in almost any pocket of soil and climate in the country. But the agriculturist is not so placed, and he must grow the varieties best suited to his conditions and requirements. First he must find them. Plant breeding has now become so highly developed that new varieties are constantly being produced, and there is always the chance that one of them may be better on a particular group of farms than any now in existence. The chance cannot be left untested. The National Institute of Agricultural Botany is prepared to examine any promising new variety provided that it is uniform and really new: to study its behaviour at Cambridge and on twelve testing stations in other parts of the country under farming conditions of high and low fertility—an extremely important point. In the case of cereals, the resistance to certain diseases and the power to stand up against lodging are studied. All normal agricultural crops, including the farmer's vegetable crops, the common brassicas, carrots, peas and others, are included in the Institute's purview—though not all the intensive horticultural crops. If the new variety justifies inclusion in the Institute's recommended varieties, the Institute helps it on to the market, multiplying up the few pounds of seed produced by the breeder to the fifty or eighty tons required for the first distribution to the trade; and then, when the seedsman has put out his allocation to his selected farmers so that they can multiply it still further, the Institute has a voluntary inspection scheme under the Seed Production Committee for all recommended varieties to see whether the crop is pure enough to go as seed. So thorough is the inspection that some 30 per cent of the crops are rejected because of weed infestation, diseases or other causes. A recent development, and one which seems to me of great importance, is that the Institute is now prepared to test some of the plant breeder's intermediates which otherwise might be discarded and lost; this has already been done at Seale-Hayne College in Devon, and an extension is planned into Norfolk and Yorkshire in the next twelve months. So the Institute acts as the link that completes the chain joining the plant breeder, the seed distributor and the farmer, and the link is strengthened by the happy relationships that exist between the Institute's staff and the National Agricultural Advisory Service.

I have had occasion to study the workings of this combination in a number of countries, and I am greatly impressed by its efficiency in Britain. Beginning with the plant breeders, we have, of course, long been fortunate. We have long had among us artists in plant breeding—you can use no other word, for they were so obviously guided by intuition and a vision of perfection for which they must always strive, though they might never attain. Such was Rowland Biffen, who fifty years ago gave us some superb wheats beginning with Little Joss—which was on the market ten years after his first crossings, compared with the fifteen or twenty years needed now; he also gave us Yeoman. Then there was E. S. Beaven, that sturdy individualist, who, scorning all State aid, with indomitable courage and persistence carried on single-handed his barley-breeding for years and produced Plumage-Archer; and there was Findlay, with the artist's eye for the potato and the artist's reluctance to divulge his technique, and Donald MacKelvie who bred the Arran potatoes. All these men, unprotected by any copyright or royalty system (such as functions in Holland) gave their productions to the world, gaining but little themselves. Dr. R. N. Salaman has recorded their labours in his very interesting book on the potato. But they are gone, and so far as I know only John Clarke, of Ballycastle, Northern Ireland, remains as a private breeder devoting most of his time to raising new varieties of potatoes. The leading seed firms, of course, maintain their plant breeding activities with results known to all of us.

But plant breeding itself has changed. I shall not discuss here whether it has become a science or a complex craft; but it has certainly steadily become more and more reduced to precise expressions and subjected to critical statistical treatment: tests of significance are replacing the artist's eye, and a staff of technical assistants is needed to cope with the great mass of detailed observations now involved. Happily, an organization of this sort can be built up wherever a good secondary school exists, and we are perhaps no longer completely dependent on that elusive creature the genius—who cannot be produced by any system of education but only discovered and nurtured. So far as can be seen, the future of plant breeding is assured in Britain. It is equally so in France. The services to Western Europeans of the great plant breeders of France—the Vilmorins, Desprez, Blondeau, Tourneur and others—are well known; indeed, France has more private plant breeders than Britain; so also has Holland. The contributions of Sweden, both from the official plant breeding station at Svalov which gave us Star, Victory and its displacer Sun II oats, and from the Weibulls at Landskrona, are equally valuable. Denmark, too, is building up an important export trade in pedigree seeds. It is an interesting fact that the exceptionally wide range of conditions in Britain makes it possible to use with advantage varieties from all these countries and from Belgium; they, however, in their much more restricted conditions, can neither draw from each other nor from the British to anything like the same extent that we can draw from them. We have even been able to use varieties which in their own country were not specially good: the most notable example of this, of course, is Atle wheat, produced in Sweden by the Weibulls, and discarded because it was too late in ripening; but it is doing remarkably well in Britain, succeeding alike in the Fens and on the thin chalk soils, and is equally popular with millers and with farmers. Yet it might so easily have never survived. Remembering how long the famous Marquis wheat of Canada remained unnoticed among the many plots at Ottawa until Charles Saunders detected it by his inelegant chewing test, one wonders whether there are other plants at present unappreciated on some experimental plots because they are too interesting to throw away but not good enough to carry forward.

Therein, of course, lies one of the great advantages of international collaboration. The Institute at Cambridge has been asked by the Organization for European Economic Co-operation to undertake two important international inquiries: a classification of the various strains of grasses, which will be done in collaboration with Dr. W. Davies, of the Grassland Research Station, Hurley; and the preparation of a scheme for uniform nomenclature and terminology for seeds. The National Institute of Agricultural Botany has also been responsible in conjunction with the French Barley Station at Maule for the preparation of a complete set of descriptions of the more important varieties of barley grown and exchanged throughout Europe. Dr. P. S. Wellington has been asked by the same Organization to conduct an international course on seed testing. Such international activities facilitate discussion and the exchange of information, thus expediting progress with the solution of one's own problems.

The search for improved varieties by plant breeding and selection and the search in the wild places by botanical exploration is going on in many lands, and many interesting and potentially valuable sorts are being produced. But in many countries the work gets but little further. When I was last in India in 1951 seeing with admiration the excellent plant-breeding done at New Delhi, Coimbatore and other centres, I asked as to what proportion of the total acreage is sown with these improved varieties. The answer was very interesting. For sugar cane and cotton the proportion was high. The peasant grows sugar cane for the factory, and delivers it there; from the factory also he receives the seed for the new crop. Nearly 90 per cent of the total area was under improved varieties using selected seed. The same applies to cotton. But for the other crops—the cereals, the millets, and the oil seeds grown for local consumption—the proportion was much less: about 20 per cent in the case of wheat, less for rice (by far the most important food crop in India) and very small for the millets, the pulses and the oil seeds. For these crops there is no effective machinery whereby the improved varieties can get into the peasant's hands; there is no reputable and completely trustworthy seed trade in close touch with the peasants to take over the plant-breeder's small stock, and arrange for its multiplication and distribution to them. A government department has undertaken the task; but retail distribution on a credit basis is not really an appropriate government activity. The same problem arises in Africa. New and better strains of some of the crops have already been produced; but in the absence of a completely reliable seed trade the multiplication and distribution of the seed is impeded. We rather take our seed trade in Britain for granted, and would never doubt a guarantee of one of our great houses: it is difficult for us to realize how drastically this whole business of crop improvement would be hampered without it.

Although systematic plant breeding is so recent a development—within the lifetime of some of us—is has already achieved a surprising number of triumphs. Among cereals the extension of spring wheat it perhaps the most remarkable. Even as recently as twenty years ago there was very little in Britain, and few sorts could really be recommended; but now, thanks to the Swedish plant breeders, some excellent varieties are available. Atle I have already mentioned; another is Atson, also a Weibull product, and a third is Fylgia, which comes from Svalov, and in England in the West Country has proved even better than Atle because it ripens earlier. The Finns also have done great things with spring wheat and have evolved strains requiring less and less time between sowing and harvesting so that they can be grown farther and farther to the north: in 1922 the northern limit of wheat cultivation in Finland was about lat. 63° N.; by 1946 it had been pushed up a line stretching from beyond lat. 66° in the west to lat. 64° in the east—a really remarkable extension. The War stopped further developments; but they are being resumed. The greatest triumphs with spring wheat are, of course, in Canada, where plant breeders have been so successful that the Prairie Provinces, which as late as 1860 were deemed little suited to farming and were sold by the Hudsons Bay Company to the Canadian Government for £300,000, are now the second largest wheat producing region in the world.

There still remain problems for the plant breeder. We have got to face the fact that plant diseases and pests are likely to increase. Of course, we hope they will not, but we are steadily making conditions more favourable for them by improving transport and upsetting Nature's equilibrium in many ways. For many of these diseases and pests the chemist has devised potent destroyers; but not by any means for all—the virus diseases cannot yet be cured though their carriers may be killed. By far the best way of avoiding disease is to grow resistant varieties. Fortunately, resistant varieties are at times found wild; but by one of Nature's little ironies resistance is often tied up with commercial uselessness, and it is for the plant breeder to untie the knot and carry the genes of resistance into commercially desirable varieties.

The supply of home-grown protein ought to be increased. The bean crop is not yet all we could like. Can anything be done about aphis and chocolate spot? Or to ensure heavier podding? It is not easy to understand why so little lucerne is grown. Various lines of work are proceeding at the National Institute of Agricultural Botany which bear directly or indirectly on these problems. Even worse is the shortage of oil-producing crops in Britain. Large quantities of vegetable oil are consumed; but very little is produced. Yet we shall need it in increasing quantities, for it is made into margarine, which is likely more and more to replace butter. Prof. G. E. Blackman at Oxford and the Institute have shown that existing varieties of the edible oil crops are not generally suitable in Britain (I am not referring to linseed). Before the War, Prof. Southworth, of Manitoba, who had been very successful there in improving the soya bean, tried a number of apparently promising sorts at Rothamsted without result. So far, only one oil-producing family seems to grow well in these latitudes: the rape family. The Germans, the Swedes and the Finns have had considerable success with it: varieties have been produced in Sweden giving as much as 600 lb. of oil per acre (the average yield of oil is, of course, much less: in 1951 it was 320 lb. per acre), which would give roughly 600 lb. of margarine: in practice a mixture of oils is used, but rape oil gives roughly its own weight of margarine. Remembering that on well-managed farms in Britain, Holland and New Zealand the yield of butter fat is only 100–150 lb. per acre, and even by intensive close folding and high manuring it goes only to about 200 lb., one can see why margarine is so much cheaper than butter. Unfortunately, about half of the rape oil consists of the 22-carbon atom erucic acid type, while most of the other vegetable oils—palm kernel, coconut, groundnut, sunflower or soya—used for making margarine are of the 18-carbon atom oleic and linoleic acid types, which are perhaps better metabolized by the human body. Would it be possible to change the genetical composition of the rape by irradiation or otherwise so that the 18-carbon atom fats are built up instead of the 22? One scarcely dares to hope this: if it could be done, it would revolutionize our fat problem.

Turning from Britain to lands for the development of which we have responsibility, one of the greatest problems of the African territories is the maintenance of the soil fertility. In Britain we can do it by growing leguminous crops, especially the clovers. In the genial climate of the southern part of Australia subterranean clover has been marvellously successful —so long as the rainfall exceeds some 15–18 in. a year. But over large parts of East and Central Africa the rainfall is too low or, what comes to the same thing, the dry season is too prolonged to allow the growth of clover. It would be a great advance if some leguminous crop could be found or bred that would do for the African farmer what clover has done in Britain and in Australia. The wet regions of Africa call even more urgently for some new soil-ameliorating crops.

The National Institute of Agricultural Botany does not itself deal with these problems; but it does deal with the resulting products, and as cytology and genetics advance, new techniques of plant breeding will certainly be evolved. Already the Swedes have used artificially induced tetraploidy for getting a new variety of rye, and an X-ray technique for a new variety of winter mustard; but this is only a foreshadowing of what may come. (An important monograph on artificially induced mutations has just been published by the Royal Swedish Academy of Agriculture as a memorial to the great Nilsson-Ehle.) When the plant breeder has done all he can in finding and transferring desirable characters, some artificially induced mutation may enable him to make still further advances. In Britain also mutants are being sought: a cobalt unit has been set up at Aberystwyth for this purpose. We may be sure that the numbers of new varieties and strains will continually increase and their range will widen, making more and more demands on the staff of the Institute. We can be equally sure that the Director and staff will cope satisfactorily with these new problems, and in congratulating them on the impressive results of this year's work, we sincerely wish them equal success in the years that are to come.

THE LIPIDS IN FLOUR

OXIDATIVE CHANGES INDUCED BY STORAGE AND IMPROVER TREATMENT

By DR. T. MORAN, C.B.E., DR. J. PACE and E. E. McDERMOTT

Research Association of British Flour Millers, Cereals Research Station, St. Albans

THE fat content of wheaten flour depends on the rate of extraction, increasing from about 0·8 per cent at 40 per cent extraction to about 2·5 per cent in a wholemeal[1]. Flour is thus a relatively poor source of lipids; but they, together with lipid-soluble constituents, are important in problems both of practical and fundamental interest. Thus, for example, while oxidative deterioration of lipids is the factor limiting the prolonged storage of flour[2] yet, on the other hand, some degree of oxidation appears to be associated with the improvement in baking quality which occurs when flour is stored in air or when it is treated with certain chemical improvers. There is also an increase in the degree of oxidation of the lipids during the mixing of dough in breadmaking, and the extent of this oxidation influences the quality of the bread made from untreated flour. Another practical point is that the colour of flour is in part determined by the extent of the oxidation of some of the fat-soluble pigments. Among the questions of more fundamental interest are those concerned with nutritional aspects, including the stability of the fat-soluble, biologically active forms of the tocopherols and the degree of oxidation of the unsaturated fatty acids[3].

Some of the effects produced by the action of the flour improver, chlorine dioxide, on the lipid fraction of flour have already been examined, mainly in a qualitative manner, and reported in a previous communication[4]. It was then noted that, under certain conditions, oxidation led to the formation of polymer-like material, presumably via an initial formation of hydroperoxides[5], and that there was a reduction in tocopherol content. These changes have now been studied in greater detail.

Oxidation of Lipids in Flour subjected to Different Treatments

In the earlier article a qualitative picture of the degree of oxidation or peroxide value was obtained by adapting the thiobarbituric acid method of Wilbur *et al.*[6] to whole flour suspensions. This method, which has also been used on milk[7,8], is particularly useful in the present connexion both because of its sensitivity and its specificity. Furthermore, applied as below, it gives clear solutions suitable for measurement in a photoelectric colorimeter. The measurements have usually been made with petroleum ether extracts of the flour.

Method. The principle of the method involves: (1) reaction of the lipids with the thiobarbituric acid reagent and (2) separation of a clear solution of the pink complex (formed by the reagent with oxidized unsaturated fatty acid) from the reaction mixture. The conditions chosen for step (2) depend on the total amount of lipids present, since this influences the partition of the coloured complex between immiscible phases.

Details of the procedure, using samples containing about 50 mgm. total solids, are as follows:

Stage 1. *Reaction with the thiobarbituric reagent.* To an appropriate volume of extract, in a boiling tube, were added 1 ml. of a 5 per cent solution of trichloroacetic acid, 0·25 ml. of the commercial detergent 'Teepol' and 1 ml. distilled water. The solvent was evaporated off and 2 ml. of the thiobarbituric acid reagent of Kohn and Liversedge[9] added. The tube was heated in boiling water for 10 min. After cooling, 0·25 ml. of 'Teepol' was added and the contents transferred to a separating funnel.

Stage 2. *Extraction of the coloured complex.* The tube was washed out into the separating funnel with 1 ml. distilled water followed by 7 ml. of ethyl ether – ethanol mixture (2 : 1 v/v). The mixture was shaken vigorously, the phases allowed to separate, and the bottom phase, containing the coloured thiobarbituric acid complex, run into a 10-ml. volumetric flask. The phase remaining in the funnel was washed twice, each time with 1 ml. of aqueous ethanol (1 : 1 v/v). Each time the bottom phase was run into the flask. The contents of the flask were made up to the mark with an ethyl ether – ethanol mixture (1 : 2 v/v). Measurement of the colour of the solution from the graduated flask was made with an Eel colorimeter, filter 624, using as blank a volume of the solvent which had been subjected to the same procedure, namely, addition of reagents, boiling and phase separation. Aliquot volumes were chosen so that readings on the Eel scale were less than 40.

Table 1 gives the thiobarbituric acid values determined in this way for the lipids extracted from an untreated 80 per cent extraction flour, one week old, and for the lipids extracted from the same flour after treatment in the laboratory with the average commercial dose of nitrogen trichloride (NCl_3 or agene) and chlorine dioxide (ClO_2), namely, 60 and 30 p.p.m., respectively, applied to the whole flour. The lipids were extracted three days after treatment of the flour and the thiobarbituric acid values determined immediately.

Table 1

Flour	Untreated	Treated with nitrogen trichloride	Treated with chlorine dioxide
Thiobarbituric acid value (per 5 gm. flour)	2·1	9·7	7·0

Treatment of the flour results in an immediate small rise in the peroxide value. Differentiation between the treated and untreated flours becomes more marked, however, if the petroleum ether extracts are held at room temperature in the light.

Changes in petroleum ether extracts with time. (*a*) *Effect of different flour treatments.* The flours (untreated or treated with nitrogen trichloride or chlorine dioxide at commercial levels) were extracted at room temperature by percolating petroleum ether (40°–60°) through a column of flour (50 gm.) contained in a glass tube 2·5 cm. diameter and 45 cm. long. In each case 100 ml. extract was collected. The extracts were kept in stoppered flasks at room temperature in the light. Under these conditions, the thiobarbituric acid value increased, and eventually insoluble polymer-like material was deposited. The colour of the extracts was also measured, in the Eel photoelectric colorimeter using filter 622. Table 2 shows that these developments occur at different rates depending on the pretreatment of the flour.

In nine days the peroxide value of the extract of fresh untreated flour increased only slightly; there was a slow increase in the extract of five-week old untreated flour, a more rapid one with an eight-month old untreated flour. The value increased most rapidly in the extracts from flours treated with nitrogen trichloride and chlorine dioxide. Polymer-like material was eventually deposited in all the extracts. The time at which it occurs is related to the increase in the peroxide value. Under the conditions we have employed, deposition appears to occur when the thiobarbituric acid value reaches about 160–280 per 5 gm. flour. This means that an extract from a treated flour usually deposits material much sooner than one from an untreated flour. As the polymer-like material is deposited, the thiobarbituric acid value of the supernatant liquid falls. The effect of treatment upon the colour of the extracts is apparent in the initial readings, and relatively little further differentiation in this respect occurred within the nine days.

(*b*) *Effect of solvent used for extraction.* With each solvent, 200 gm. of an 80 per cent extraction untreated flour, two weeks old, were extracted, by irrigation through columns at room temperature. 250 ml. of each extract were collected. 100-ml.

* Thiobarbituric acid values expressed per 0·8 gm. flour

Days in light for perceptible deposition of polymer-like material: carbon tetrachloride, 10; chloroform, 19; benzene, 20; petroleum ether 27 ethyl ether, 30 (the longer time with ethyl ether is probably due to the material having a relatively higher solubility in this solvent. Thus, polymer-like material from petroleum ether is partially soluble in ethyl ether)

samples of each were held in the light and in the dark, and measurements of the colour and the thiobarbituric acid values were made initially and at intervals thereafter. The thiobarbituric acid values were determined on 1 ml. of extract, which is equivalent to 0·8 gm. of flour. For these extracts containing less than 10 mgm. total solids, a modified procedure was followed. In stage 1, 3 ml. distilled water and 1 ml. of the thiobarbituric reagent were used; addition of 'Teepol' after heating was omitted. In stage 2 the tube was washed out with 1 ml. distilled water followed by 5 ml. ethyl ether – ethanol mixture (2 : 1 v/v). The upper phase was washed only once with 1 ml. distilled water and the contents of the flask made up to the mark with ethyl ether – ethanol mixture of 1 : 2 (v/v). For this particular experiment a small sample was chosen because of the large increase in the thiobarbituric acid value which occurs in the extracts kept in the light. This results, however, in a larger experimental error with samples with a low thiobarbituric acid value. For these it is preferable to use, as in Table 2, a volume of extract equivalent to 5 gm. flour. The results obtained are given in Table 3.

In the dark all the extracts are comparatively stable. In the light, extracts in carbon tetrachloride and chloroform rapidly autoxidize and become bleached. This also occurs with the other solvents but less quickly, petroleum ether extracts showing the greatest stability.

Reducing Substances in the Unsaponifiable Fraction

The unsaponifiable fraction of flour lipids contains pigments, steroids and tocopherols. It is an important fraction, since it contains components which contribute to the antioxidant properties of the parent flour. These influence the colour and determine the vitamin E content; some of them are extremely sensitive to oxidation, and this is reflected in a diminution of the total reducing value of the unsaponifiable fraction[4].

The reducing value of the unsaponifiable fraction towards the system ferric chloride α-α′-dipyridyl is largely due to α- and β-tocopherols, to an unidentified substance first noted by Brown[10,11] on paper chromatograms, afterwards observed by Eggitt and Ward[12] and in the present work, to carotenoid pigments and possibly sterols. From our observations using chromatographic techniques, about 40 per cent of the total reducing value is due to α- and β-tocopherols and about 30 per cent is due to the unidentified substance. Details of this aspect of the work will be published elsewhere.

Saponification of the flour lipids and measurement of the total reducing value of the unsaponifiable fraction were carried out by the methods of Tosic and Moore[13]. The colorimetric estimations were made with an Eel photoelectric colorimeter (filter 624). A standard curve was prepared using synthetic α-tocopherol, and the figures for total reducing value are expressed in terms of the reducing value of α-tocopherol.

The sensitivity of the total reducing value as an index of the treatment of flour with an oxidizing agent is illustrated in Table 4, in which values for an untreated flour are compared with those for the same flour when treated with nitrogen trichloride in the laboratory at about the commercial level. (In commercial practice it is not the final flour which is treated; instead, the constituent mill-streams are given different levels of treatment. The figures of 60 and 30 p.p.m. for nitrogen trichloride and chlorine dioxide respectively are the mean values calculated on the weight of the final flour.) The table also includes values for two flours (80 per cent extraction) both of which had been stored under the same con-

Table 4

Flour	Treatment	Total reducing value of unsaponifiable fraction (μgm./100 gm flour)
Same stock 2 weeks old	None	2,220
	NCl_3 15 p.p.m.	1 660
	,, 30 ,,	1,180
	,, 60 ,,	410
Same stock 8 months old	None	2,140
	Treated with NCl_3 at mill	470

ditions for eight months. One of these was untreated and the other was from the same batch of flour but which had been treated with nitrogen trichloride at the mill.

Lipids extracted from Different Types of Flour

Measurements of the kind described above have been made on lipids extracted from a range of flours, and are given in Table 5. These include flours freshly milled in the laboratory, of 80, 70, 85 and 100 per cent extraction, from a good-quality Manitoba wheat, and samples sent to us of recently imported commercial consignments of Canadian National flour.

Table 5

Flour	Total reducing value of unsaponifiable fraction (μgm. /100 gm. flour)	Colour of petroleum ether extract (100 ml. extract from 50 gm. flour)	Thiobarbituric acid value expressed per 5 gm. flour
Series 1. Untreated and chemically treated 80% extraction flour			
Untreated flour *A* 2 weeks old	2,830	10 5	2·1
Treated flour *A*			
ClO_2 7·5 p.p.m.	1,030	9·3	—
,, 15 p.p.m.	465	6·2	—
,, 30 p.p.m.	120	2·6	7·0
NCl_3 15 p.p.m.	1.660	6·1	—
,, 30 p.p.m.	1,180	4 5	—
,, 60 p.p.m.	410	2 6	9·7
Untreated flour *B*, 8 months old	2,140	10·5	2·4
Same flour *B*, but treated NCl_3 at mill	470	4 0	3·0
Series 2. Laboratory milled untreated flours of different extraction (Manitoba grist)			
80% extraction	1,600	9·7	—
70% extraction	1,930	10·0	—
85% extraction	3,020	12·2	—
100% extraction	3,420	8·2	—
Bran	5,700	7·8	—
Commercial germ	33,700	84·0	—
Series 3. Imported Canadian National flours (history unknown)			
Sample 1	2,360	10·1	2·0
,, 2	1,256	5 0	—
,, 3	1,270	5·2	—
,, 4	1,410	5·9	—
,, 5	750	3·4	19 0
,, 6	1,290	4·6	2 0
,, 7	1,200	4·7	6·6
,, 8	750	3·7	18·8
,, 9	330	1·8	8·0
,, 10	1,830	8·3	2·0

These data show that the total reducing value is the most sensitive index of the effect of the gaseous flour improvers. These agents have an immediate marked effect on this value, which is much less affected by storage of the flour. Similarly, the colour of the extracted pigment is more sensitive to the action of the improvers than it is to normal atmospheric oxidation. It should be noted that this may not hold when the flour is wetted, made into a dough and agitated in air or oxygen. These conditions are then more favourable for the action of oxidizing enzyme systems which may be coupled with the bleaching of the pigments. Although flour stored in air for several months shows only a relatively small reduction in the figure for total reducing value and the colour of the extracted pigment, there is a steady rise in the peroxide value of the extracted lipids, as measured by the thiobarbituric acid test.

These observations suggest that one of the immediate results of the application of the gaseous improvers is a reduction in the effectiveness of the antioxidants present in the flour, notably the tocopherols. This is consistent with the comparatively rapid rise in the peroxide value when extracts from flours so treated are held at room temperature in the light. By contrast, the antioxidants are less susceptible to atmospheric oxidation; but the lipids, possibly the phospholipid fraction, undergo a slow oxidation which is reflected in the peroxide value.

The results with the flours of different extraction are of interest in relation to the anatomical parts of the wheat grain. The figure for total reduction value rises with the extraction, while the colour due to pigment extracted with petroleum ether rises up to 85 per cent extraction, but is less with a wholemeal than a 70 per cent extraction flour. This behaviour is due to the high figure for the total reducing substances in the germ and bran, the high value of the figure for the extracted pigment from germ and the relatively low value for bran. The 80 and 70 per cent flours are mainly endosperm material, while much of the germ and some bran is contained in the 85 per cent extraction flour.

One practical application of these observations is that they indicate the basis of a method of deciding whether or not a flour has been treated with one of the gaseous improvers (nitrogen trichloride or chlorine dioxide). (The bleaching agent, benzoyl peroxide, would probably react in similar fashion; but as it leaves an equivalent residue of benzoic acid its use could readily be checked.) Thus, in the Canadian samples examined it would be inferred, for example, that sample 1 and probably 10 were wholly untreated, whereas sample 9 and probably samples 5 and 8 had been given our normal commercial improver treatment for 80 per cent flour. It would also appear that the remaining five samples had received some degree of treatment. This aspect of the work, however, requires a comprehensive survey with a wide range of samples of flour of known history (grist, extraction-rate, age, etc.) in order to standardize it.

RADIOISOTOPE CONFERENCE AT OXFORD

THE Second Radioisotope Conference organized by the Atomic Energy Research Establishment, Harwell, was held at Oxford during July 19–23, with the object of discussing the experimental uses of radioisotopes and new techniques in their various applications in medicine, biology, agriculture, chemistry, physics, engineering and industry. The organizers of the Conference took the bold step of accepting only seventy-one out of more than two hundred papers which were proffered; this removed the usual scourge of conferences—an overcrowded programme and multiple sessions in parallel. Another notable achievement was the issue of preprints of all the papers well in advance of the Conference, and the limitation of the time of reading each paper to ten minutes; this allowed a considerable amount of time for discussion, which was very lively and stimulating.

The Conference started off with several papers dealing with the therapeutic applications of radioactive isotopes. Some of these are used as external applicators much in the same way as radium, but utilizing the special advantages offered by the new radioactive substances. R. C. Tudway, H. F. Freundlich and T. S. M. Marshall (Bristol) used iridium-192 as a cervix applicator; the soft γ-rays from iridium make shielding of neighbouring organs much easier. Similarly, yttrium-90, which was used by F. Crainz (Catania), lends itself to intra-uterine application, as it is a pure β-ray emitter. F. Ellis and R. Oliver (Oxford) demonstrated the use of tantalum wire containing tantalum-182 as an applicator; the great flexibility of these wires makes them less likely to obstruct blood vessels than the rigid radium needles.

The internal use of radioisotopes in therapy depends on the ability to concentrate the radioactivity in the organ to be irradiated. One such method, which may be used for the treatment of cancer of the lung, was developed by E. E. Pochin, G. B. Cook, R. M. Cunningham, A. Hollman, F. Hudswell and B. R. Payne (University College Hospital, London, and A.E.R.E., Harwell). Colloidal gold, containing gold-198, is precipitated on sugar charcoal particles which are too large (30–43 μ in diameter) to pass through the lung capillaries. If injected intravenously they will therefore be concentrated in the lungs, with only a very small fraction reaching the liver. This preparation can also be localized in any specified area of the lung by means of cardiac catheterization. J. Van der Werff (Nijmegen) described a somewhat similar use of bismuth-206 for deposition in the reticulo-endothelial system.

In the field of diagnosis, radioiodine is still the chief isotope employed in a variety of new problems. Very interesting results were obtained by H. G. Thode, C. H. Jaimet and S. Kirkwood (Hamilton, Ontario) on the uptake of iodine-131 by the salivary glands. It appears that a simple procedure, the comparison of the activity in a sample of saliva with that in the blood, provides a very sensitive method of discriminating between various types of thyroid disorders; the mechanism of the uptake in the salivary glands is not quite clear. The possibility of diagnosing carcinoma of the thyroid by means of a simple iodine-131 test was described by J. Rotblat and G. Owen (St. Bartholomew's Hospital, London), and the technique of outlining the thyroid and the location of tumours was improved by H. C. Allen, jun., J. R. Risser and J. A. Greene (Houston, Texas), who employed for this purpose a crystal spectrometer with a double discriminator coupled to a scanning and recording device. A comparison of the behaviour in the body of iodine-131 and its analogue astatine-211 has been carried out by J. G. Hamilton, P. Wallace-Durbin and M. W. Parrott (Berkeley, California); astatine, being an α-emitter, offers many advantages over the β-emitting iodine isotopes, but Dr. Hamilton emphasized the dangers involved in handling this element. Most of the experiments were carried out on rats; but the few studies on humans indicated some promising applications. The use of serum albumin labelled with iodine-131 for the determination of cardiac output was described by N. Veall, J. D. Pearson, T. Hanley and A. E. Lowe (Guy's Hospital and Hammersmith, London), who used a scintillation counter placed over the region of the heart and connected to a ratemeter and chart recorder; the method has still to prove its value, but the advantages it offers as compared with older methods of cardiac output measurements merits further study.

Iron-59 has been used in several investigations carried out in the Royal Cancer Hospital, London. E. M. Ledlie and C. Baxter described some clinical applications of this isotope in hæmatological investigations, particularly in the study of erythropoiesis bone marrow diseases. L. F. Lamerton, E. B. Harriss and E. H. Belcher carried out animal experiments on erythropoiesis and the effects of X-ray irradiation; they obtained very interesting results on protection achieved by shielding of the spleen. S. Rowlands, T. Freeman and P. C. Fleming (St. Mary's Hospital, London) developed a technique for making blood volume determinations in animals by the simultaneous use of two isotopes, phosphorus-32 and chromium-51. The latter isotope was also used by J. S. Robertson, R. Milne and S. H. Cohn (San Francisco) for observing the distribution of blood platelets in rats.

A somewhat unique use of radioisotopes was presented in a paper by F. P. Bowden, J. B. P. Williamson and P. Laing (Cambridge) on the metallic transfer in screwing and bolting which they studied by the autoradiograph technique using radiochromium. The connexion of this work with medicine arises from the fact that in operations on fractured bones a certain amount of metallic transfer may occur, sufficient to form an electrolytic couple which has a harmful effect on the healing of tissue.

J. ROTBLAT

St. Bartholomew's Hospital.

One session was devoted to methods of labelling compounds with carbon-14, tritium and iodine-131, three of the nuclides most used in medical and biochemical studies. In addition, the method of preparation of tritium used at the Atomic Energy Research Establishment was outlined by W. J. Arrol,

J. Chadwick, J. Eakins, C. Evans and E. J. Wilson. R. F. Glascock (National Institute for Research in Dairying) reported on the use of tritiated compounds for studying the metabolism of dietary stearic acid by the lactating goat. Acetic anhydride labelled with tritium and carbon-14 had been employed by P. Avivi, Sylvia A. Simpson, J. F. Tait and J. K. Whitehead (Middlesex Hospital) to elucidate the structure of electrocortin and to estimate it and hydrocortisone in human peripheral blood. A paper from the National Institute for Medical Research described how high specific activity rabbit fibrinogen, albumin, normal and antibody globulins had been formed by biosynthesis using whole dried algae, labelled with carbon-14. The preparation of the algae had already been reported to the conference by J. Catch (Radiochemical Centre, Amersham). G. Wolf, B. Connor Johnson and S. G. Kahn (University of Illinois), who have synthesized vitamin A-2-^{14}C, gave preliminary experimental results on its metabolism after injection into rats. An invigorating discussion followed the note by E. Kallee (Tubingen) on the detection of as little as 0·001 μgm. of proteohormone insulin by paper electrophoresis after intravenous injection of rats with radioactive iodide, iodine-131 labelled serum and insulin. The use of cobalt-60 labelled vitamin B_{12} (C. Rosenblum, U.S.A.), the biosynthesis of penicillin (H. R. V. Arnstein) and the use of carbon-14 labelled sugars in the study of carbohydrate metabolism of the leaf (Helen K. Porter and L. H. May) were among some of the other contributions of interest to biochemists.

Among the papers dealing with plant nutrition and allied subjects, L. Ehrenberg, I. Granhall, A. Gustafsson and N. Nybom (Sweden) gave an interesting description of their first season's work on the irradiation of growing plants (barley, fruit trees, etc.) with a cobalt-60 gamma-ray source. The fruit trees showed a series of morphological aberrations such as clustering of leaves and shoots, formation of bifurcated shoots and irregular leaves. The topical subject of foliar fertilization has been studied by K. Kamdl (Austria) with phosphorus-32 labelled phosphatic nutrient. In the discussion, R. Scott Russell (Oxford) pointed out the large amount of fundamental work still to be done before the practical usefulness of foliar nutrition could be assessed. Another approach to the problem of making phosphorus available to plants was that of O. Talibudeen (Rothamsted), who had carried out experiments using phosphorus-32 to determine the readily exchangeable phosphates in soils.

Papers of interest to chemists included a description of the meticulous work by C. J. Collins and W. A. Bonner (Oak Ridge, Tennessee) on the use of carbon-14 to investigate the Wagner–Meerwein rearrangement in the study of 1 : 2 : 2-triphenylethanol and its derivatives. Various aspects of the labelling of ring labelled compounds were dealt with by H. S. Turner (Chemical Research Laboratory, Teddington). The experiments of A. G. Maddock and H. Behrens (Cambridge) on the exchange reaction between iodine and methyl iodide provoked much useful discussion. The kinetics of the process were outlined, and it was shown that there was a chain reaction initiated by radiation which involved the production of free radicals. The branching of vinyl polymers (J. C. Bevington and H. W. Melville, Birmingham), the use of carbon-14 to study the role of oxygenated radicals in the Fischer–Tropsch reaction (E. J. Gibson and A. W. Fletcher, Fuel Research Station, Greenwich), and the poisoning of solid catalysts used in the synthesis of ammonia (C. Bokhoven, Netherlands) illustrated further applications of the radioisotope technique.

A beautiful illustration of the usefulness of tracers combined with radioactivation analysis was given by P. Albert, F. Montariol, R. Reich and G. Chaudron (France) in their investigations of the purification of aluminium from zinc, copper, sodium and silicon by zone melting. Another interesting metallurgical paper was that by M. C. Inman, D. Johnson, W. L. Mercer and R. Shuttleworth (University of Leeds) describing their careful measurements on the self-diffusion coefficients of copper and zinc into alpha- and beta-brass.

In the first of two important practical applications of neutron sources, C. P. Haigh (Barrow Hospital, Bristol) described a measurement of the neutrons generated in the ^{24}Na$(\gamma,n)^{2}$H reaction as a method of assay for heavy hydrogen. In the discussion on the paper by A. H. Knight (Macaulay Institute for Soil Research, Aberdeen) on the measurement of soil moisture by neutron scattering, no satisfactory reason was found why organic matter in the soil did not have a greater practical effect on the measurements reported. Results obtained on archæological specimens with the new carbon-14 dating method developed by A. R. Crathorn and W. R. Loosemore (Royal Institution and Atomic Energy Research Establishment) were presented. The method involves the conversion of the specimen into acetylene which is used as the filling gas in a proportional counter. The supplementary method of B. N. Audric and J. V. P. Long (Chemical Research Laboratory, Teddington), utilizing the acetylene dissolved in a liquid phosphor at − 78° C., has not yet been used for dating specimens.

Of the two new thickness gauges of interest to industry, that developed by J. L. Putman, S. Jefferson and J. F. Cameron (Atomic Energy Research Establishment) was very ingenious. The method was developed for measuring from the outside of pipes the degree of corrosion on the inside of the pipe wall. The gamma-ray source is cobalt-60 and the scintillation counter detector has a gating circuit so that only radiation which has suffered a change of energy by scattering from the pipe wall is measured. One advantage of this system is that no heavy lead shielding is required. Other industrial applications included the use of phosphorus-32 labelled wool fibres to study the very difficult problem of drafting (D. S. Taylor, Leeds), a study of water flow and velocity measurements (A. Montens, Germany) and the wear of carbide-tipped cutting tools (L. G. Erwall, Sweden). Of the papers dealing with new nuclides for use in industrial gamma radiography, that utilizing thulium-170 (gamma energy 84 keV.) was of most immediate practical importance. In the final paper L. E. Brownell and J. V. Nehemias (University of Michigan) illustrated how a ten-thousand curie cobalt-60 gamma-ray source was used for sterilizing foodstuffs by irradiation, and mentioned briefly the very interesting possibilities of initiating chemical reactions by this means. A short closing address was given by Dr. Henry Seligman, head of the Isotope Division, Atomic Energy Research Establishment, who has been primarily responsible for initiating the two Radioisotope Conferences that have been held.

The papers presented at the Conference, together with the discussions, will be published in book form in November 1954 by Butterworths. There will be two volumes: vol. 1 will cover medical and physiological applications, and vol. 2 physical sciences and industrial applications.

In addition to the formal papers, there were films illustrating radioisotope techniques used in hospitals and laboratories. By the courtesy of Lord Cherwell, the Clarendon Laboratory was available for a well-laid-out exhibition covering instruments, laboratory techniques and a representative range of manufacturers' equipment (representing five different countries) of interest to radioisotope users. This was a centre of activity throughout the week.

J. E. JOHNSTON

CHEMISTRY IN RELATION TO THE DEVELOPMENT OF THE NERVOUS SYSTEM

THE Mental Health Research Fund organized the First International Neurochemical Symposium at Magdalen College, Oxford, during July 13–17. The Symposium was planned as part of a series, and the field selected for the first meeting was "Chemistry in Relation to the Development of the Nervous System". The organizing committee consisted of J. Elkes (Birmingham), L. Flexner (Philadelphia), J. Folch-Pi (Boston), G. W. Harris (London), S. S. Kety (Washington), D. Richter (Cardiff) and H. Waelsch (New York).

The Symposium was attended by approximately seventy scientific workers, forty being from abroad—from Belgium, Canada, Denmark, Germany, Italy, Norway, Sweden, the United States and U.S.S.R. It was arranged in morning and afternoon sessions, and on two days there was also an evening session. Each session started with one or two reviews, followed by communications on recent research; there was always a lively and full discussion, and this was recorded. The transcription of the Symposium will be published in the near future by the Academic Press, New York.

The first morning session, under the chairmanship of Sir Geoffrey Vickers, was characterized by two features: the regrettable absence of Dr. R. Lorente de Nó (New York), and the view expressed by the two anatomists in discussing some aspects of the early development of the nervous system (Prof. J. D. Boyd, of Cambridge) and of the vascular patterns of the nervous system (Dr. Horne Craigie, of Toronto) that chemical inductors are required for explaining the morphological development of the nervous system. Prof. Boyd emphasized the importance of the tissue and the spaces underlying the ectoderm in the development of the dorsal plate and the differentiation of the neural tissue, illustrating his points with a wealth of material from sheep embryos. Dr. Horne Craigie showed the wide range of vascular patterns presented in the development of a variety of species, and posed the question of the extent to which the pattern is determined by underlying changes.

The afternoon session, with Dr. R. W. Gerard (Chicago) in the chair, opened with a review of experimental neuroembryology in the chick by Dr. V. Hamburger (St. Louis), and an account of the functional development of the nervous system in the dogfish by Dr. H. P. Whiting (Bristol). Dr. Hamburger took up the theme of the morning session and reported on the dramatic changes in the growth of spinal and sympathetic ganglia produced by the influence of transplanted limb buds and tumour tissue. Dr. Whiting presented experimental evidence for dividing the developmental steps into the classical divisions of myogenic, neurogenic and reflexogenic, and in general supported the Coghill thesis of segregation of reflexes. There followed a communication by Dr. J. L. Malcolm (London) on his investigations into the appearance of inhibition and facilitation in the developing spinal cord of kittens. He showed that, during the first two post-natal days, an impulse sent in through the dorsal lumbar roots leads only to a single spike in the corresponding ventral root, but that later, with the appearance of after-discharge in the ventral root, facilitation and inhibition can be demonstrated. The session ended with a communication from Dr. D. Hill (London), in which he emphasized the important practical aspects of cerebral maturation as marked by the milestones which can be demonstrated by the electroencephalogram rhythms.

The second day started, under the chairmanship of Dr. S. S. Kety, with a detailed review by Dr. Folch-Pi of the composition of the whole brain of mice during post-natal maturation, with particular reference to phospholipids, a review which was based to a great extent on the extensive work done in his own laboratory. This review was followed by Dr. H. Klüver's (Chicago) careful fluorospectrographic analysis of porphyrins in the central nervous system. They are not present in the central nervous system of reptiles, amphibians and fishes, and are found in warm-blooded animals only after birth—for example, in rats at the age of 20–25 days, a time which is associated with a number of functional advents. Porphyrins occur first in the ventral roots and last in the cerebrum; Dr. Klüver thinks their presence is related to the developing oligodendroglia. These photodynamic substances may be affected by the amount of light known to be transmitted through the skull in some species, and the interesting question arises as to the extent to which light may, by these means, affect nervous system activity and also, perhaps, the sexual cycle. Dr. P. Diezel (Heidelberg) presented histochemical evidence of the distribution of iron throughout the brain substance, and pointed out the considerable amounts which appear in the glial cells during development, while Dr. G. Brante (Eskilstuna) reported on the presence of polysaccharide substances in the nervous tissue of developing mice. Dr. A. F. W. Hughes (Cambridge) described his technique for the refined densitometry measurements of ribonucleic acid in the developing chick embryo, and was able to demonstrate its appearance and distribution in the ventral horn cells and its relationship to the Nissl substance. The morning session finished with an account by Dr.

D. R. Davies and Dr. L. C. Thomas (Salisbury) on their infra-red spectrophotographic method for measuring quantitatively the myelin in the developing nervous tissue. They stressed the point that this method might be applicable to a number of problems associated with myelination.

The afternoon session, under the chairmanship of Prof. H. A. Krebs, started with a carefully worked out review by Dr. D. Richter (Cardiff) on the chemistry, particularly enzymes and substances such as acetylcholine, glutamic acid and glycine, in the developing brain. The material, which was often given in clear tables, will be of great use for subsequent reference when published in the Symposium. Dr. S. S. Kety (Washington) reported on his work, with the nitrous oxide method, on the oxygen consumption of the brain in the human, and made the observation that at birth nearly 80 per cent of the oxygen consumption is accounted for by brain metabolism, that between ten and twenty years the percentage is more than 50, and that later it falls to about 25 per cent. Then Dr. H. McIlwain (London) gave an account of his experiments, together with Dr. P. Greengard, on the oxygen consumption of tissue slices of the cerebral cortex of rats and guinea pigs of varying ages. They showed how the oxygen consumption can be raised to an increasing extent with age by means of electrical potential gradients in the Warburg chamber, the presumption being that such potentials stimulate the cortical tissue to activity comparable to that found *in vivo*. The role of non-nervous tissue was assessed by comparable measurements on gliomas. Dr. R. W. Sperry (Pasadena) followed with an account of the effects of transplanted skin in tadpoles and its effect on subsequent innervation, and, most intriguing, the re-organization of the connexions in the central nervous system.

An evening session was held on the second day, and for this the chair was taken by Dr. L. B. Flexner (Philadelphia). The subject of the geometrical properties of the constituents of the nervous system was ably outlined by Dr. A. Pope (Boston), who discussed, among other problems, the quantitative aspects of inter- and intra-cellular material. The remainder of the evening was devoted to histochemistry of a most refined nature. Dr. O. H. Lowry (St. Louis) gave a fascinating account of his technique for weighing and the subsequent chemical analysis of individual neurones, a feat which won the universal admiration of the audience, as did his apparently casual method of presentation. No less interesting was Dr. H. Hydén's (Gothenburg) description of his methods of measuring the light and X-ray absorption of single nerve cells, from which the lipid protein and ribonucleic acid content can be assessed. How many of his audience envied him a machine which automatically types the results!

On the morning of the third day, with Sir Rudolph Peters in the chair, Dr. H. Waelsch (New York), opened by reviewing the differences in the rate of replacement of substances in the developing and adult brain; the results were obtained with the use of the isotope technique. He showed that in the first week of the developing brain of rats 40 per cent of the fatty acids is replaced, whereas there is a much smaller turnover in the adult rat. With the exception of glutamine, he has obtained no evidence that amino-acids are synthesized into the adult brain; however, from experiments on tissue cells there is some indication that essential amino-acids may be synthesized in immature brain tissue; but the mechanism of the uptake of these amino-acids is not clear. He stressed the point that in the embryonic or immature brain the blood–brain barrier appears to be absent; but so far the number of substances examined is not sufficiently large to allow this general conclusion. He was followed by Dr. H. E. Himwich (Galesburg), who gave an account of the relative rates of uptake of glutamine by adult and young rat brain, concluding that the rate of uptake in the younger age group is relatively greater. The lipid content of the brain was discussed by Dr. W. M. Sperry (New York) as well as by Dr. R. M. C. Dawson (Oxford). Dr. Sperry's results were obtained from human material from 4 to 40 days post natal, and he emphasized the need to correlate the increased lipid content over this period not only with the rate of medullation but also with the changes in the water and nervous tissue space. Dr. Dawson presented evidence of the rate of deposition of phospholipids in the young mouse brain, and presented evidence for a phospholipid metabolic cycle. Prof. A. V. Palladin (Kiev) read a paper on the metabolism of nucleic acids in the developing brain. Investigations in his Institute have shown that the protein content increases during the development of the brain, that despite the concomitant decrease in nucleic acid content the metabolism increases, that the grey matter of the cerebrum has a higher content of nucleic acids, of ribonuclease, and of desoxyribonuclease than the white matter, and that the cerebellum is rich in nucleic acids, especially desoxyribonucleic acid. He stressed the important role of these substances during the morphological and functional development of the brain. Prof. G. E. Vladimirov (Leningrad) in his report dealt with the role of the blood–brain barrier, and presented data collected during the turnover of such substances as adenosine triphosphoric acid, creatine phosphate, etc., using labelled phosphorus. By estimating the iron in blood, in brain tissue free from blood, and brain tissue containing blood, the quantity of blood contaminating the brain tissue was assessed, and errors in estimating the true intracellular content of phosphorus avoided. By such experiments the specific activity of intracellular inorganic phosphates is found to be equal to that of adenosine triphosphate.

The afternoon, with Dr. W. Feldberg (London) in the chair, saw the presentation of a great deal of evidence for the change in enzyme content in relationship to age. Dr. L. B. Flexner (Philadephia) opened with a survey of the growth of various enzyme systems in the guinea pig cortex, and he was able to relate their appearance with that of the cortical electroencephalogram, the presence of strychnine spikes, and the development of the earliest movements evoked by stimulation of the cortex. He presented evidence for a large increase in the chloride and sodium space at a time (forty-sixth day) when recognizable electroencephalogram patterns and strychnine spikes are observed. In the ensuing discussion some scepticism was expressed about the interpretation of the difference between sodium and chloride spaces in terms of Hodgkin's theory of a sodium pump mechanism as a basis for neuronal activity. Both Dr. H. E. Himwich (Galesburg) and Prof. J. Elkes and Dr. A. Todrick (Birmingham) presented figures for the rate of appearance of cholinesterases in the various parts of rat and rabbit brain, while Dr. M. A. Gerebtzoff (Liège) presented histochemical studies of the distribution of cholin esterases in the rat spinal cord. None of these findings could yet be directly tied to actual functional investigations. The session concluded with a paper by Dr. W. K. Jordan (Little Rock) on the increase of adenosine triphosphate in the rat cortex and cerebellum during the first forty days after birth. The increase was correlated with the appearance of spontaneous action potentials which began as short bursts of activity. In the cortex the periods between the bursts greatly decreased between the tenth and twentieth day; in the cerebellum at a somewhat later period.

Prof. L. S. Penrose took the chair on the morning of July 16, when Dr. Salome G. Waelsch (New York) outlined some of the genetic factors involved in the development of the central nervous system, in which she gave a stimulating account of her own work on mutations of mouse central nervous system. Of particular interest were her experiments in the modification of genes by antigen–antibody reactions, and her preliminary findings indicate an extremely interesting future for this method of investigation. The second review, by Prof. E. Klenk (Cologne), was on the possible role of cerebrosides in the pathology of the nervous system. Two short papers presenting original material by Dr. R. W. Gerard and Dr. L. Abood (Chicago) and by Sir Rudolph Peters (Oxford) completed the morning. Drs. Gerard and Abood have investigated the chemistry of the nervous system of the *Dba* strain of mice which between the twenty-eighth and thirty-sixth day post-natal is extremely susceptible to auditory stimulii. Dr. Gerard suggested that the low adenosine triphosphatase activity found at this period could account for the apparent hyper-excitability of the nervous system, if the membrane potential is related to the creatine phosphate content. Sir Rudolph Peters spoke about his interesting experiments on convulsions produced by fluorocitrate and its probable mode of action as a competitive inhibitor of aconitase; he discussed the probable reasons for the inability to reverse the competitor by calcium.

In the afternoon session, under the chairmanship of Prof. R. Gjessing (Oslo), the chemical changes accompanying well-defined mental defects were considered. Prof. L. S. Penrose (London) spoke about the genetic factors involved in the transmission of a number of known metabolic deficiencies, and Dr. H. Bicket (Birmingham) described the control of phenylketonuria by a suitable diet in several cases which he had studied in collaboration with Dr. Gerrard and Dr. Boscott. Finally, Dr. H. Weil-Malherbe (Runwell) presented data on the relationship of blood adrenaline to a large series of mental diseases.

The evening session was devoted to films. Dr. Hughes showed, by means of some extremely good time-lapse photography, the growth processes of chicken neurones, growing in suitable culture media; a fine sequence showing mitosis of a neurone was included in this film. Dr. Feldberg showed a film made by him and Dr. S. Sherwood of the method used for introducing drugs beyond the blood–brain barrier directly into the lateral ventricles of the cat. The action of a series of drugs producing changes of awareness such as stupor, catatonia and anæsthesia, as well as motor effects such as scratching, itching, paralysis and convulsions, were clearly shown with this film. He stressed the fact that from this region of the brain we can easily produce, by the action of small amounts of drugs, conditions which have much in common with mental diseases in man—for example, epilepsy and schizophrenia. Dr. H. Bickel's (Birmingham) short film of the three cases of phenylketonuria, which had been discussed earlier in the day, showed dramatically the recovery which is possible with a diet low in phenylalanine. His film emphasized the difficulties inherent in the control of such cases and the need of hospitalization. Finally, a sound film from Prof. D. Bovet's laboratory in Rome demonstrated skilfully the use of the electroencephalogram in the investigation of drug effect on the central nervous system.

In the closing session on the morning of July 17, with Dr. H. Kluver in the chair, the high standard of the previous days and the intense interest which had been shown in the discussions at all previous sessions were maintained. Prof. G. W. Harris (London) gave a brief but extremely lucid account of the early endocrine–nervous system relationships, with particular reference to the growth of control by the hypothalamus on the pituitary, and indirectly on other endocrine organs. Dr. D. Nachmansohn (New York) gave a short account of his conception of the basic biochemistry associated with the conduction of the nerve impulse, indicating the points in the energy cycles involved at which drug action might be expected to take place. The remaining papers related, in varying degree, to clinical problems, emphasizing their important place beside the highly theoretical discussions which had taken place on the previous days. Dr. J. T. Eayrs (Birmingham) described the relationship of a nerve cell and its background substance in cases of hypothyroidism, with particular reference to the probable inability of dendrites to grow when the background substance is deficient. Dr. M. Reiss (Bristol) presented evidence of the relationship between steroid hormone deficiencies and the incidence of mental states, and Dr. S. P. Hicks (Boston) showed the selective action of a number of agents, such as X-rays, on different parts of the developing nervous system. He gave some interesting data on the selective action of drugs, such as acetylpyridine, on certain parts of the nervous system. Finally, Dr. J. Elkes (Birmingham) spoke of the work done in collaboration with Dr. Eayrs and Dr. Todrick on the effect of inhibition of cholinesterase in the central nervous system during the period of development, pointing out that 80 per cent inhibition of this enzyme has little interference with subsequent development and function.

The closing remarks, presented by Prof. R. Gjessing (Oslo), admirably expressed the opinion and the feelings of all those present. He expressed their gratitude to the organizers for bringing such a comprehensive group of workers together, and felt that, if the symposium had only emphasized the many gaps in our knowledge, that alone would have made it worth while. He expressed the admiration of the meeting for the extreme thoroughness of the organization, which attended not only to their serious discussions but provided a most enjoyable evening in Magdalen College Hall with entertainment from the Oxford Madrigal Society and others. In fact, much of the success of the meeting was no doubt due to the many opportunities for informal discussion in the delightful surroundings of Magdalen College.

The Flavour of Porridge

Nowadays, porridge is often insipid and lacking in its traditional flavour and aroma. Possibly one reason for this is that, in England at least, sugar is usually added, and the sweetish taste, while it does not mask any true porridge flavour, is sufficient for most people. In Scotland, on the other hand, the majority add salt—precisely why, despite many inquiries, we have been unable to ascertain—so that the porridge flavour is more important. In any event there is a traditional flavour, often described as 'nutty', associated with Scotch porridge, and it is the view of many that if this flavour were more general the consumption of porridge would increase.

Any flavour in porridge meal or flakes is developed during the initial kilning process. This is not a standard operation. The whole oats are dried down from a moisture content in the range 14–20 per cent (but usually about 17 per cent) to a final moisture content of 4–8 per cent, after which they are shelled and ground into meal. The source of heat may be coke or anthracite, and in the past oat husk was often thrown on the fire presumably with the object of producing some volatile product which then gave the kilned oat its flavour. The conditions of heating are not, however, constant as from one kiln to another, or in one operation within a single kiln. Broadly speaking, if the kilning is carried out at low temperatures (not exceeding about 80° C.) the resulting meal or flakes have no distinctive taste, whereas if the temperature is sufficiently high the meal will have a caramel-like bitterness or even a burnt flavour.

As part of a programme of research for the Oatmeal Millers of England and Scotland, we are investigating the physics of kilning, and inevitably we have also considered the problem of flavour. The full results will be published elsewhere; but meanwhile it is of interest to record that we have consistently produced the desirable porridge flavour by careful control of the conditions of kilning. The furnace gases, despite traditional belief, play no part, and the same flavour is obtained when the air is heated in an electric furnace. The optimum conditions correspond to the gentle drying of the oats down to an intermediate moisture content of about 8 per cent followed by a short toasting for twenty minutes in a current of air at 150° C. These conditions are, of course, not absolutely rigid, and a slight increase in the temperature can be compensated by a corresponding decrease in the time of toasting. The use of high air temperatures at the surface of the partly dried grain to obtain a short but severe heat treatment at the final stage of kilning is the essential feature. On crushing the grain the pleasant aroma is immediately apparent. It soon evaporates from exposed meal; but the flavour is associated with less volatile material and accordingly more persistent.

The work of Baker, Parker and Fortmann[1] has indicated that the aroma and flavour of bread are due largely to numerous organic substances produced in the crust at temperatures around 150° C. The substances thus produced range from the more volatile aldehydes like furfural and pyruvic aldehyde to the melanoidins associated with the browning reactions occurring in the crust. Similar reactions will occur in the kilning of oats, since the outer portions of the grain reach about the same temperature and also undergo slight browning. However, there would appear to be other substances produced which are responsible for the unique flavour of oatmeal. Thus, in laboratory tests we have found that the optimum conditions of heating to produce flavour in oats also apply to groats, albeit there is less tolerance to over-treatment and a tendency for a slight rancid flavour to be produced due to the absence of the protective husk. On the other hand, we have failed to produce the same characteristic nutty oatmeal flavour in wheat when it is submitted to similar treatment.

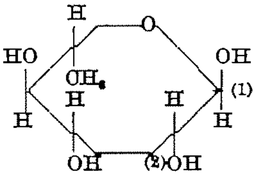
Sweetness and Configuration in Rhamnose

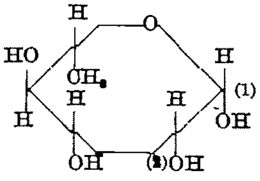
The ordinary form of most reducing sugars, such as α-glucose, β-fructose and α-galactose, becomes gradually less sweet after dissolution, and in the meantime the sweetness reaches a constant value, since the ordinary form is converted in part into the less sweet isomer, and finally an equilibrium is attained between the two isomers : $\alpha \rightleftharpoons \beta$.

Several years ago, one of us[1] pointed out that the sweeter form of these reducing sugars always has *cis*-hydroxyl groups on the carbonyl and adjacent carbon atom, while in the less sweet isomer the hydroxyls on the two carbon atoms are *trans* ; this was confirmed[1,2] by isolating and testing the α- and β-anomers with respect to sweetness.

From this rule it would be expected that in L-rhamnose the ordinary form (I) would be less sweet than the β-form (II), because the hydroxyls on C_1 and C_2 of the latter are *cis*. It has now been found that this is so.



α-L-Rhamnose
(I)



β-L-Rhamnose
(II)

Three tasters compared the sweetness of a 4·29 per cent (calc. as anhydrous) solution of α-L-rhamnose ($[\alpha]_D^{23}$ − 13° → + 8·6°) with that of a 3·86 per cent solution of β-L-rhamnose ($[\alpha]_D^{23}$ + 41° → + 8·8°). Immediately after dissolution the β-rhamnose solution was, in spite of its lower concentration, much sweeter than the α-rhamnose solution ; but with time the sweetness of the two solutions became closer, and after the lapse of fifteen minutes they were found equal in sweetness. After a further interval, the positions were reversed, the latter being distinctly sweeter than the former. From this experiment it is possible to calculate the ratio of the degree of sweetness of the α- and β-form, as in the case of fructose[2].

The content of the α- and β-form in the two solutions at the moment of equal sweetness (15 min. after dissolution) was estimated by measurement of the mutarotation :

	$[\alpha]^{25}_{D}$	α-form	β-form
3·86 per cent β-rhamnose	+ 12°	54 per cent	46 per cent
4 29 per cent α-rhamnose	+ 6°	65 per cent	35 per cent

Representing the ratio of the sweetness of α- and β-rhamnose by x, it was found to be 0·39 from the relation, $(46+54x)/(35+65x) = 4{\cdot}29/3{\cdot}86$; that is, the sweetness of the α-form is less than two-fifths that of the β-form. This ratio is somewhat greater than that for fructose (0·33)[2], but much smaller than that for glucose (0·67)[1], showing that the difference of the sweetness of the α- and β-form of rhamnose is very remarkable. This fact is probably related to the comparatively rapid mutarotation.

Molybdenum in the Growth and Metabolism of *Chlorella*

RECENT papers have shown the need of molybdenum for the growth of *Chlorella*[1] and *Scenedesmus*[2]. Some observations on the effect of molybdenum deficiency on the metabolism of *Chlorella* are recorded here.

Chlorella pyrenoidosa was cultured in purified nutrient solution in 250-ml. Erlenmeyer flasks with continuous shaking and illumination provided by fluorescent lights giving a light-intensity of 1,200 ft. candles at the base of the flasks. In Table 1 the effect of molybdenum on growth as measured by dry weight, chlorophyll content, photosynthesis and respiration of *Chlorella* cultures after five days growth is presented (means of four replicates).

Table 1 EFFECT OF MOLYBDENUM ON GROWTH (DRY WEIGHT), CHLOROPHYLL, PHOTOSYNTHESIS AND RESPIRATION OF *Chlorella*

Added Mo (μgm./l. culture)	Dry wt. (gm./l culture)	Chlorophyll (% dry wt.)	Photo-synthesis*	Respiration†
0	0·87±0 09	1 0±0·2	38±3	16 ±1
10	1·10±0·06	3·4±0·2	139±2	7·9±0 9

* Oxygen evolution expressed as ml. oxygen/gm. dry wt./hr., not corrected for respiration.

† Endogenous oxygen uptake expressed as ml. oxygen/gm. dry wt./hr.

Molybdenum-deficient cultures are characterized by their low chlorophyll content, and expressed on a unit dry-weight basis, low photosynthetic rate and high rate of endogenous respiration. The marked reduction of chlorophyll content of molybdenum-deficient cells has been reported by Arnon *et al.*[2] for *Scenedesmus*, and is perhaps one of the most characteristic features of molybdenum deficiency. The dry weight of molybdenum-deficient *Chlorella* cells was only slightly lower than that of the controls. In this respect, *Chlorella* at first sight behaved differently from *Scenedesmus*, in which molybdenum deficiency was associated with a sharp reduction in growth as measured by dry weight[2]. Recent results obtained by Arnon and Ichioka (unpublished), however, have shown that the dry weight, but not the chlorophyll content, of molybdenum-deficient *Scenedesmus* cells was markedly increased by the addition of vanadium, an element found to be essential for this alga[3]. In this respect the dry weight of the molybdenum-deficient *Chlorella* cells as shown in Table 1 is comparable to the dry weight found by Arnon and Ichioka for molybdenum-deficient *Scenedesmus* cells receiving vanadium.

The depression of photosynthesis in the absence of molybdenum is approximately proportional to the depression in chlorophyll content. Regardless of whether other factors were operative, the observed reduction of photosynthesis in molybdenum-deficient cells could be accounted for solely by their lower chlorophyll content.

Endogenous respiration was remarkably high in molybdenum-deficient *Chlorella*. In homogenized leaves of molybdenum-deficient tomatoes, Nason *et al.*[4] observed a marked lowering of endogenous respiration, a condition which might have been due to preparatory treatment. Spencer (unpublished results) has found increased respiration in molybdenum-deficient tomato leaves.

One of us (J. F. L.) gratefully acknowledges financial assistance from a Hackett studentship and a studentship from the Commonwealth of Australia Scientific and Industrial Research Organization. We wish to thank Dr. Victoria H. Lynch of the Radiation Laboratory for a culture of *Chlorella pyrenoidosa*.

Incorporation of Acetate-2-^{14}C into Human Erythrocyte Stroma as a Function of Storage

IN an effort to elucidate the changes which may occur in the dynamic state of stroma constituents during storage of human erythrocytes (reported in part at the "Symposium on the Structural and Cellular Dynamics of the Red Blood Cell", June 1953 : National Research Council, Washington, D.C.), we have studied the incorporation of acetate-2-^{14}C into red cell stroma under *in vitro* conditions using a technique previously described[1]. Venous blood from healthy donors was drawn under sterile conditions into cold *ACD* solution (each 100 c.c. of the *ACD* solution contained 2·45 gm. glucose, 1·37 gm. sodium citrate and 0·50 gm. of citric acid ; 0·24 c.c. of *ACD* solution was added to each c.c. of blood) and then distributed as aliquots into an appropriate number of sterile tubes. These tubes were carefully sealed to prevent evaporation and were stored in two groups, one group at 4° C. and the other group at 37° C. At the intervals indicated in Fig. 1, tubes

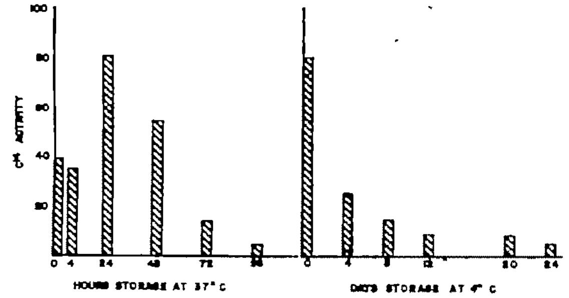

Fig. 1

were removed from the storage conditions and the incorporation of acetate-2-^{14}C into the total stromal fraction of the stored cells was determined. The composition of the incubation mixture for measurement of acetate incorporation was: 12·0 ml. of *ACD*-preserved whole blood, 1·5 ml. isotonic phosphate buffer at *p*H 7·4, 0·6 ml. of 0·3 *M* glucose in 0·9 per cent sodium chloride, and 1·5 ml. of sodium acetate-^{14}C (approximately 80 mgm.) in 0·9 per cent sodium chloride. The total amount of radioactivity added as labelled acetate varied from $4 \cdot 9$ to $6 \cdot 3 \times 10^6$ disintegrations per minute per 12 ml. of whole, preserved blood.

The results of these experiments are shown in Fig. 1. They indicate that upon storage at either temperature there is a progressive loss in the ability of the erythrocyte stroma to incorporate acetate-2-^{14}C. After storage at 4° C. for four days, acetate incorporation decreases to 70 per cent of the initial value. There is a significant rise in incorporation of acetate after storage for 24 hr. at 37° C., followed by a rapid, progressive decrease in incorporation to about 70 per cent of the initial level after 72 hr. of storage at this temperature. After 96 hr. of storage at 37° C., the acetate incorporation exhibits a degree of depression comparable to that seen after twenty-four days of storage at 4° C. A rise in acetate incorporation comparable to that seen after 24 hr. of storage at 37° C. may well have occurred in the experiment where the red cells were stored at 4° C., but may have been undetected, because the first determination was carried out four days after storage was initiated.

These studies indicate that the ability of human red cells to incorporate acetate-2-^{14}C into the stromal fraction is diminished under storage. The diminution of the ability to incorporate acetate is dependent upon the temperature of storage, and may reflect alterations in the dynamic state of the stroma lipids under these storage conditions. Similar conclusions have been reached with respect to lipids and lipoproteins by Lovelock[2] in his studies on thermal shock in red cells. The technique employed here demonstrates an abnormality of erythrocyte stroma metabolism which occurs during storage at 4° C. at a much earlier time than the appearance of significant changes in post-transfusion viability of the red cells.

Upon storage of red cells in *ACD* at 37° C., the time required for these changes in acetate incorporation to occur is much shorter. This suggests that certain *in vitro* studies of red cell metabolic capacity designed to elucidate the abnormalities of red cell metabolism occurring upon storage at lower temperatures might appropriately be carried out at 37° C. The use of these high temperatures of storage might facilitate future studies of some of the abnormalities of red cell metabolism by similarly shortening the time-scale of such experiments.

This communication is based in part on work performed under contract with the U.S. Atomic Energy Commission at the University of Rochester Atomic Energy Project, Rochester, New York. These studies were aided by contracts between the University of Rochester and the Office of Naval Research, Department of the Navy (NR 102–174) and the Public Health Service (A-537-C4).

A Position Effect of the *Rh* Blood-Group Genes

The opportunity has arisen of comparing the *C* and *E* antigens in the red cells of donors whose genotypes contain the same *Rh* genes, *D*, *C*, *E*, etc., but in different alignments.

Two comparisons have been made: that between red cell samples 1 and 2 in the table, and that between samples 3 and 4. All four samples gave reactions of about equal strength with some anti-*C* and some anti-*E* sera (columns *y* and *z*); but with other sera wide differences were revealed (columns *u*, *v*, *w* and *x*).

Scores representing the Strength of Reaction of Four Samples of Blood against Titrations of Six Selected Antisera

Genotype of donor	Antisera anti-*C* (*u*)	anti-*C* (*v*)	anti-*E* (*w*)	anti-*E* (*x*)	anti-*C* (*y*)	anti-*E* (*z*)
1. *dCE*/*dce*	0	2	73	87	93	34
2. *dCe*/*dcE*	39	55	6	13	93	24
3. *DCE*/*Dce*	0	0	75	71	75	33
4. *DCe*/*DcE*	34	43	29	31	91	33

All four genotypes have been confirmed by family groupings.
Genotype 1 has a frequency in Caucasians of perhaps 1 in 20,000.
" 2 " " " " " " about 1 " 10,000
" 3 " " " " " " " 1 " 10,000.
" 4 " " " " " " " 1 " 10.

The samples were taken on the same day within a few hours and in the same manner. Other examples of genotypes 1, 2 and 4 have been tested with similar results; we know of no other example of genotype 3. Control *dCe*/*dce* and *dcE*/*dce* samples showed that the gene *f* is not playing any detectable part in the *CE* effect.

The words *cis* and *trans*, introduced into genetics by Haldane, are useful here: in terms of *C* and *E*, samples 1 and 3 represent the *cis* arrangement and samples 2 and 4 the *trans*.

The influences of the *Rh* genes on each other are certainly very complicated; nevertheless, by confining ourselves to these two straightforward comparisons it is clear, from rows 1 and 3, that when *C* and *E* are in the *cis* arrangement *C* is inhibited and, from rows 2 and 4, that when *C* and *E* are in the *trans* arrangement *E* is inhibited. (The depression of *E* in genotype 4 though definite is not so extreme as that in genotype 2.)

A difference in phenotype between heterozygotes in *cis* and *trans* is precisely the sort of effect which, in other species, is such a striking characteristic of closely linked genes—genes between which crossing-over is rarely but regularly observed. Two examples may be quoted, namely, the lozenge genes of *Drosophila melanogaster*[1] and the biotin requirement genes of *Aspergillus nidulans*[2,3]. In these examples two genes may appear to behave as allelomorphs in *trans* but not in *cis*, a phenomenon which has been called by Lewis[4] "position pseudo-allelism". However, the reactions of most anti-C and anti-E sera (exemplified by y and z in the table), together with the reactions of anti-c and anti-e, have never allowed C and E to be mistaken for allelomorphs.

A New Solvent for Silk

It has been shown recently by Schurz[1] that solutions of silk in phosphoric acid undergo a considerable decrease in viscosity on standing, which is probably due to degradation of the silk. Silk is insoluble in formic acid, although the latter is an excellent solvent for many polypeptides and nylon. On the other hand, concentrated aqueous solutions of many inorganic salts, for example, halides[2] and thiocyanates[3] readily dissolve silk, in some cases without degradation of the fibroin[4,5].

We have found that silk is very readily soluble in formic acid containing small quantities of water and certain inorganic salts at room temperature. Up to 20 per cent (w/v) of silk may be dissolved in these solutions, which are then semi-solid. Salts which are effective for rendering silk soluble in formic acid include lithium chloride, bromide, iodide and thiocyanate, magnesium, calcium, strontium, zinc and manganese chlorides, and calcium and barium bromides, whereas the alkali metal halides are almost ineffective. The salt concentration is related to the water-content of the formic acid. Thus, using 90 per cent (w/w) acid 10 per cent (w/v) anhydrous calcium chloride is necessary, whereas with 98 per cent formic acid, only 2 per cent calcium chloride is required.

It is seen from the table of viscosity measurements that formic acid solutions of silk undergo far less degradation on standing than do solutions in phosphoric acid. The raw silk (from Lullingstone Castle Silk Farm, Kent) was first freed from sericin by treatment with a warm dilute solution of soap and ammonia, followed by washing with distilled water and drying at 110° C. Viscosities were determined in an Ostwald viscometer at 25° C., after filtering the solution through glass wool. Intrinsic viscosities $[\eta]$ were obtained by plotting reduced viscosities, η_{sp}/c (c is silk concentration in gm./100 ml. solution), against silk concentration for four values of the latter, over the range 0·2–1·0 per cent, and extrapolating the resulting straight lines to $c = 0$.

Upon dilution with water, followed by vigorous agitation, the silk is precipitated from formic acid – calcium chloride solutions as a white curd. Alternatively, the silk may be obtained as a film by spreading the solution on a glass plate, allowing the solvent to evaporate in a desiccator over solid sodium hydroxide, followed by washing with ethyl alcohol to remove calcium chloride.

Infra-red absorption curves of the material precipitated by water show it to be in the β-configuration. It is of interest, however, that films cast from formic acid – calcium chloride, without removal of the salt show a carbonyl peak characteristic of the α-form of silk, although other features of the spectrum are rather obscure.

We thank Mr. G. J. Weston, of this Department, for the infra-red examination of these materials.

Inhibition of Vernalization in *Linum usitatissimum* Linn. by Certain Synthetic Hormones

The present communication summarizes the results of eight hours prechilling soaking treatment at room temperature with different concentrations (500, 50, 5, 0·5, 0·05 and 0·005 parts per million in distilled water) of α-naphthaleneacetic acid, indolylbutyric acid and indolylacetic acid on the process of vernalization in *Linum usitatissimum* Linn., strain 477–3/2. Soaked seeds from each treatment were spread over cloth moistened with a solution of the same strength or with water and kept in Petri dishes inside a refrigerator, maintained at a temperature of 4–8° C. Mucilage on the seed-coat retained the solutions during the entire period of chilling (24 days), and this ensured a continuous supply of hormones to the embryo.

Only sprouted seeds of similar stages of development were used for sowings along with water-treated unvernalized seeds. Date of opening of the first flower on each individual plant was recorded, and the average number of days taken from date of sowing

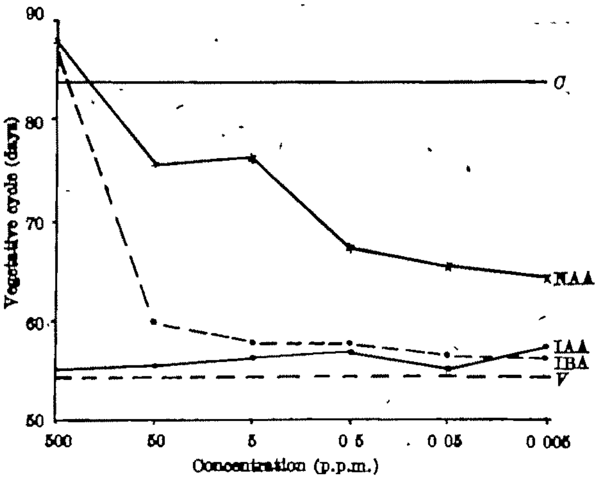

Fig. 1. Vegetative cycles of plants raised from *Linum* seeds treated with different concentrations of hormones before chilling. *C*, control; NAA, α-naphthaleneacetic acid; IAA, indolylacetic acid; IBA, indolylbutyric acid; *V*, vernalized

to anthesis for each treatment was calculated. This has been termed the vegetative cycle. The statistical validity of the experiment was determined by analysis of variance.

Of the three hormones, α-naphthaleneacetic acid was found to be the most effective, at all the concentrations, in reducing the period of earliness in flowering (Fig. 1 and Table 1). This delaying effect is directly proportional to the strength, since it brings down the earliness of 29·9 days, recorded in plants raised from water-soaked vernalized seeds, to 19·6 days at the lowest and to − 3·7 days at the highest concentration. In plants raised from seeds treated with 500 p.p.m. of this hormone, there is not only a complete inhibition of flowering induced by vernalization, but also a delay of 3·7 days, which is significant at the 5 per cent level.

Table 1. EFFECT OF PRECHILLING TREATMENTS OF *Linum* SEEDS WITH DIFFERENT CONCENTRATIONS OF HORMONES ON THE VEGETATIVE CYCLE OF PLANTS RAISED FROM THEM
Date of sowing: October 17, 1953

* Significant at 1 per cent level.
† Significant at 5 per cent level.
Error mean square = 29·5.

Indolylbutyric acid in the highest concentration brings about a complete nullification of the chilling effect. Vegetative cycles of plants raised from seeds treated with 50, 5 and 0·5 p.p.m. of this hormone are slightly higher than that of the normal vernalized plants and these differences are statistically significant. The same cycles do not differ significantly in plants from seeds treated with the lower concentrations (0·05 and 0·005 p.p.m.). Similar results were obtained with all the concentrations of indolylacetic acid.

Destruction of photoperiodic effects, in certain plants, through the application of synthetic hormones, is now established. But with the exception of that of Wittwer[1] and Pillai[2], there are few observations on the effect of growth substances on the process of vernalization. Wittwer[1] recorded that treatment of lettuce seeds with dichlorophenoxyacetic acid (2,4-D) during the process of chilling resulted in an inhibition of flowering induced by vernalization. Pillai[2] observed a significant decrease in earliness in flowering in *Brassica campestris* L. through a pre-vernalization soaking of seeds in 50–0·005 p.p.m. of dichlorophenoxyacetic acid.

I have suggested earlier[3] that the substance or substances formed during chilling are not direct flower-forming ones and thus differ from those synthesized in the leaves during a photoperiodic treatment. Similarity of action of certain hormones on the nullification of photoperiodic and vernalization effects, however, indicates that the above conclusion is true of the final product of vernalization only, and there is every likelihood of the existence of an intermediate step common to both vernalization and photoperiodism in the chain of reactions leading to the ultimate induction of earliness in flowering.

Relation between Vitamin D and Vitamin B_{12}

IN some experiments on chick growth with wholly vegetable diets[1] supplemented with pure vitamin B_{12}, a relationship became evident between the growth-stimulating effect of this vitamin and the content of calcium, iron and vitamin D of the diet. In an attempt to elucidate the relation between the vitamin D and vitamin B_{12}, the present experiment was started.

Day-old White Leghorn chicks from non-depleted hens were, during their first week, given a wholly vegetable diet (207 in Table 1), without added vitamin D. Then they were weighed and according to their weight grouped in six equal groups, each consisting of four sub-groups with nine chicks. They were fed the same diet with different vitamin D and vitamin B_{12} supplements. The experimental period lasted three weeks, and the results are given together with the experimental plan in Table 2.

Table 1. PERCENTAGE COMPOSITION OF EXPERIMENTAL DIET 207

Barley	22·3
Oats	14·9
Wheat bran	11 0
Corn meal	15·1
Soybean oil meal	16 6
Sunflower seed meal	10 5
Alfalfa meal	4 0
B-vitamin conc.*	1·0
Bone meal	2·0
Ground limestone	1·6
Salt mixture†	1·0
	100·0

* Minimum 200 mgm. riboflavin, 200 mgm. niacin and 20,000 I.U. thiamin per kgm.

† 896 gm. iodized NaCl (5 mgm. KI per kgm.), 50 gm. $MnSO_4.4H_2O$, 50 gm. $FeSO_4.7H_2O$, 4 gm. $CoSO_4.7H_2O$.

Table 2. CHICK GROWTH AND FEED CONSUMED PER UNIT GAIN (UNTIL FOUR WEEKS OF AGE)

Group No.	Vitamin D supplement			Vitamin B_{12} (μgm. per kgm. diet)	Gain‡		Feed per kgm. gain (kgm.)
	Cod liver oil* %	Deltafor D_2—400† %	Approx. I.U. per kgm. diet		abs. (gm.)	rel. %	
1	0	0·05	200	0	128	100	3·06
2	0	0·05	200	30	134	105	3·01
3	0·4	0·1	640	0	110	86	3·45
4	0·4	0·1	640	30	141	110	3·03
5	0·4	0·3	1,400	0	106	83	3·29
6	0·4	0·3	1,400	30	144	112	3·04

* 1,000 I.U. vitamin A, 60 I.U. vitamin D per gm.
† 400 I.U. vitamin D_2 per gm.
‡ Gain between one and four weeks, average males–females.

From this table it is evident that the two higher vitamin D supplements had significant growth-depressing effects in the groups with no vitamin B_{12}. Supplementing the diet with vitamin B_{12}, however, eliminated these effects.

Details of this and other experiments in this series will be published elsewhere.

Deoxyribonucleoproteins of Cell Nuclei: Sensitivity to X-Rays

STUDIES of aqueous systems of intact deoxyribonucleoproteins[1] showed that they were markedly unstable. Storage at 2°–5° C. for 24–36 hr. produced a substantial depolymerization of the deoxyribonucleic acid component. This is in marked contrast to the stability of dissociated nucleoproteins in 1·0 *M* sodium chloride. It was felt that this instability might be functionally significant in the mechanism of radiation effects on biological systems. Studies were therefore made of the effects of X-radiation on aqueous nucleoprotein gels.

When isolated calf-thymus nuclei are placed in water, there is a rapid gelation, an increase in volume, and lysis of the nuclei. Further additions of water produce a further increase in the volume of the gel, a concomitant decrease in rigidity, and eventually an aqueous nucleoprotein solution. Such gels have a high and anomalous viscosity and are very susceptible to degradation, losing viscosity rapidly at 25°, more slowly at 2°–5° C. When they are exposed to low doses of X-rays no immediate effect is apparent. After 4–6 hr. storage of the irradiated gel at 2°–5° C., there is an acceleration of the spontaneous loss of viscosity. The effect is proportional to dose in the range studied (250–5,000 r.).

The observed effect is a decrease in the structural viscosity of the nucleoprotein gel and relates to the interactions between deoxyribonucleoprotein molecules. In 1·0 *M* sodium chloride, the structural viscosity of the nucleoprotein gel is abolished, and the nucleic acids and proteins are dissociated. Under these conditions it is possible to measure the intrinsic viscosity of the deoxyribonucleic acid. The doses of X-radiation used had no effect on the intrinsic viscosity of the deoxyribonucleic acid, whereas the spontaneous loss of viscosity of non-irradiated gels involves depolymerization and a decrease of intrinsic viscosity.

Exposure of isolated nuclei to 1,000 r. of X-rays markedly decreases the capacity of these nuclei to swell when placed in water. This is in agreement with previous observations[2] that X-rays inhibit trypsin-induced swelling in salivary glands of *Drosophila* larvæ.

With regard to the loss of viscosity observed in the nucleoprotein gels, there are apparently at least two separate factors involved. The lack of any immediate effect of X-radiation on the gel or on its deoxyribonucleic acid component strongly suggests that the observed phenomena involve primarily the interactions of the protein moieties of these systems. Further details of this work will be published in due course.

This investigation was supported in part by a research grant (*PHS RG*-149) from the National Institutes of Health, Public Health Service, to Dr. B. P. Kaufmann.

Analysis of Unordered Tetrads Segregating for a Lethal or Other Epistatic Factor

Perkins[1] and Whitehouse[2] have shown how chromosome centromeres can be mapped by the analysis of unordered tetrads of spores (or gametes), provided segregation is occurring at three unlinked loci. The basis of the method is the determination of the frequency of tetratype tetrads for the loci considered in pairs. If at one of the three loci there is segregation for a lethal or other epistatic factor, the frequency of tetratype tetrads with respect to the other two loci will be indeterminable. Nevertheless, it is still possible to map the genes in relation to their centromeres.

Consider first the general case of tetrads segregating for three pairs of unlinked genes, *A* and *a*, *B* and *b* and *C* and *c*. Five classes of tetrads can be recognized:

Class	Genotype of tetrad	Ditype (*D*) or tetratype (*T*)		
		A and *B*	*A* and *C*	*B* and *C*
I	*ABC* *abc* *ABC* *abc* *ABc* *abC* *ABc* *abC* *AbC* *aBc* *AbC* *aBc* *Abc* *aBC* *Abc* *aBC*	*D*	*D*	*D*
II	*ABc* *abC* *ABC* *abc* *Abc* *aBC* *AbC* *aBc*	*D*	*T*	*T*
III	*ABC* *abc* *AbC* *aBc* *ABc* *abC* *Abc* *aBC*	*T*	*D*	*T*
IV	*ABC* *abc* *Abc* *aBC* *ABc* *abC* *AbC* *aBc*	*T*	*T*	*D*
V	*ABc* *abc* *AbC* *aBC* *ABC* *abC* *Abc* *aBc*	*T*	*T*	*T*

Tetrads of class I are ditype with respect to all three combinations of the loci in pairs. As indicated, there are four possible constitutions for this type of tetrad, depending on whether the pairs of factors show the parental combination or whether some show recombination. However, if the three loci are unlinked, these four sub-classes are expected with equal frequency. Tetrads of classes II, III and IV are ditype with respect to one pair of loci, tetratype with respect to the other two. In each instance, there are two sub-classes, one with the ditype pair in the parental combination and the other non-parental, and again these are expected with equal frequency. Tetrads of class V are tetratype with respect to all three combinations of the loci in pairs.

Segregation at the first division of meiosis for all three loci will give rise only to class I tetrads. Segregation at the first division at two loci and at the second division at the third locus will give rise to either class II or class III or class IV tetrads, depending on which locus shows second division segregation. Segregation at the first division at one locus and at the second division at the other two will give rise with equal frequency to class V tetrads and to either class II or class III or class IV tetrads, depending on which locus shows first division segregation. Segregation at the second division for all three loci will give rise to classes I, II, III and IV with equal frequency. Expressed algebraically, if the frequencies of segregation at the second division of meiosis for the three loci *A*, *B* and *C* are x, y and z respectively, the frequencies of segregation at the first division being $1-x$, $1-y$ and $1-z$, respectively, then the frequencies of the five classes of tetrads are as follows:

Class	Frequency
I	$(1-x)(1-y)(1-z)+\frac{xyz}{4}$
II	$z(1-x)(1-y)+\frac{xy(1-z)}{2}+\frac{xyz}{4}$
III	$y(1-x)(1-z)+\frac{xz(1-y)}{2}+\frac{xyz}{4}$
IV	$x(1-y)(1-z)+\frac{yz(1-x)}{2}+\frac{xyz}{4}$
V	$\frac{xy(1-z)}{2}+\frac{xz(1-y)}{2}+\frac{yz(1-x)}{2}$

Now, if *A* is a lethal or other epistatic factor, suppressing the difference in phenotype of one or both of the other pairs of factors, then classes IV and V cannot be distinguished from one another; but they can be separated collectively from the other three classes (I, II and III), which can also be distinguished from each other. If p, q and r are the observed frequencies (as fractions of the total tetrads) of classes I, II and III, respectively, then we have three simultaneous equations for x, y and z. The solutions to these equations are as follows:

$$x = \frac{-b \pm \sqrt{b^2-4ac}}{2a},$$

where

$$a = 3(p-q-r)+1,$$
$$b = 3[(p+q)(p+r)-2p+q+r]-1,$$
$$c = 4[p-(p+q)(p+r)],$$
$$y = \frac{2(x+p+q-1)}{3x-2},$$
$$z = \frac{2(x+p+r-1)}{3x-2}.$$

As an example of the use of these formulæ, Hartshorne[3] has analysed ninety-two tetrads of *Chlamydomonas reinhardi* segregating for three unlinked factors: 'eyeless' (*ey*), mating-type (*mt*) and 'small colony' (*sc*). The 'small colony' character is suppressed in the presence of the normal allele of 'eyeless'. In the analysis above, *A* is the epistatic locus and must therefore be equated with *ey*. Let *mt* equal *B* and *sc* equal *C*. The frequencies observed by Hartshorne for the different classes of tetrads are then as follows:

Class	I	II	III	IV+V	Total
Frequency	2	9	6	75	92

Hence

$$p = \frac{2}{92}, \quad q = \frac{9}{92}, \quad r = \frac{6}{92},$$

and, applying the formulæ, we obtain either

$$x(ey) = 0{\cdot}979, \quad y(mt) = 0{\cdot}210, \quad z(sc) = 0{\cdot}140,$$

or

$$x(ey) = 0{\cdot}080, \quad y(mt) = 0{\cdot}910, \quad z(sc) = 0{\cdot}947.$$

Further data make it possible to discriminate between these two alternatives. Hartshorne analysed 151 tetrads segregating for *ey* and the unlinked character 'slow growth' (*sg*), and found 9, or 5·96 per cent, were tetratype. This indicates that both these factors are situated close to their centromeres. Hence, the second of the above alternatives is the true one. It is concluded that the second division segregation frequencies for *ey*, *mt* and *sc* are 8·0, 91·0 and 94·7 per cent, respectively, and the genes are located 4·0, 45·5 and 47·3 units from their respective centromeres.

Papazian[4] and Spiegelman[5] have pointed out that the simple procedure of halving the second division segregation frequency to obtain the map distance of a locus from its centromere is inaccurate unless the map distance is short. However, their correcting formula is inapplicable to second division segregation frequencies in excess of 2/3, such as those for *mt* and *sc* above. It appears impossible to correct accurately map distances obtained from second division segregation frequencies, except by the study of intervening loci. Thus, a second division segregation frequency of nearly 100 per cent implies that one cross-over is occurring proximal to the locus in question at nearly every meiosis, that is, that double cross-overs are rare, and hence that the map distance is approximately half this frequency. On the other hand, a second division segregation frequency of about 67 per cent may mean that one cross-over proximal to the locus is occurring in two-thirds of meioses and hence a map distance of 33 units is correct, or it may mean that several cross-overs proximal to the locus are occurring at every meiosis, and hence that the map distance between locus and centromere is perhaps 150 or 200 units. It is convenient to retain the customary procedure of halving the second division segregation frequency to obtain an estimate of the map distance from the centromere, while remembering the limitations of the method.

A New Antibacterial Principle : Megacine

IN the course of an investigation of the potential lysogenic powers of *B. megaterium* strains isolated recently from faecal and soil samples, one of the strains studied (No. 216) showed a particular effect. When a highly diluted broth culture of this strain was mixed with a heavy suspension of a phage-sensitive *B. megaterium* strain ('mutilate'), and plated on yeast extract agar containing casein hydrolysate, no phage plaques were seen, but the colonies of the strain 216 were surrounded by a small clear halo. To study this effect, young aerated cultures of the strain grown in yeast extract – casein hydrolysate broth were lightly irradiated with ultra-violet light and reincubated. The turbidity of these cultures increased after irradiation up to the end of the second hour; then a lysis of the bacteria set in, which became almost complete in three hours. The bacterial lysate thus obtained does not contain phage particles when tested in the usual way. On the other hand, if one drop of various dilutions (up to a few thousands) of the lysate was put on the surface of a yeast-extract – casein hydrolysate agar plate heavily seeded with *B. megaterium*, it caused a clear spot with no bacterial growth on the site of the drops. There was no reproduction of the antibacterial principle (which we propose to call 'megacine') in the sensitive bacteria, which fact excludes its phage character.

The lysates obtained by irradiation of young growing cultures containing approximately 10^7 cells/ml. were active up to dilutions of 10^{-3}–10^{-4}, depending on the *B. megaterium* strains used as test organism. All the thirty-seven strains of *B. megaterium* investigated, whether lysogenic or not, were sensitive to the antibacterial principle. The most striking was that the producer, the strain 216, was also sensitive to the principle, though to a lesser degree (10^{-2} dilution) than the others. On the other hand, when a considerable number of strains belonging to various other species of bacteria were tested, none of them was found to be sensitive to megacine. The figures in parenthesis show the number of strains investigated: *E. coli* (8), different *Salmonellae* (10), *Shigellae* (4), *Ps. aeruginosa* (3), *Proteus X*-19 (1), *Proteus morgani* (1), *Ae. aerogenes* (1), *Serratia marcescens* (1), *Micrococcus pyogenes*, var. *aureus* (4), var. *albus* (7), *M. tetragenus* (1), *Sarcina flava* (4), *Diplococcus pneumoniae* types 1, 2, 3, 14 (7), *Str. viridans* (1), *Str. faecalis* (3), *Str. haemolyticus A, B, C* (15), *C. diphtheriae* (1), *C. xerosis* (1), *B. anthracis* (8), *B. cereus* (6), *B. subtilis* (7). All the strains of *Sarcina flava* investigated were, however, sensitive to lysozyme, which fact indicates the dissimilarity in the mode of action of lysozyme and megacine. The principle is very slightly diffusible in agar, does not pass through parchment and is moderately thermolabile. Ninety per cent of its activity is destroyed at 80° C. in 30 min., although heating at 60° did not diminish its antibacterial effect. The principle was precipitated by ammonium sulphate at 75 per cent saturation. Trypsin inactivated the active principle.

Megacine is lethal for the cells of *B. megaterium*. If it is added to a light suspension of this bacillus, the organisms are killed within minutes and partly lysed by the fifth to sixth hour. It cannot be classed as an antibiotic, for its characteristics are more closely related to the bacteriocines[1], which are represented so far by colicines[2] and pyocine[3]. There is, however, a striking difference between megacine and these antibacterial principles, namely, both pyocine and colicines are bactericidal only for certain strains of their own or related species, and the strains producing the principles are not sensitive to their own bacteriocine. The unique feature of megacine lies in its effect on the very strain which produces it.

Full details of these observations will be published in the *Acta Microbiologica Hungarica*.

Sensitive Parallax Detector for Optical Bench

IN accurate measurements of focal-lengths and the like, on an optical bench, it is customary to employ the points of pins mounted on adjustable stands. The lens under test has itself to be so mounted as to enable it and the pin-points to be 'lined up' parallel to the tracks of the optical bench. This is a somewhat troublesome and time-consuming operation, and distracts the students' attention from the basic aim of the experiment. The device herein described eliminates much of this tedious procedure and can indeed yield more accurate settings than the older procedure. As it is easily adaptable to any type of optical bench, I will confine myself to describing the details peculiar to the device itself.

A 'herring bone' pattern, such as that shown in Fig. 1, consists of some two dozen parallel lines which interact an equal number of parallel lines inclined at an angle of 175° to the first set. This is reproduced photographically on lantern slides. As finished, the slides show a pattern of intensely black lines spaced about 3 mm. apart and about 0·1 mm. thick, on a clear background. Of course, the slides are covered with clear glass and bound as usual.

These slides are clamped with spring clips on brackets mounted on the stands which slide on the optical bench. No precise centering is required; all that is necessary is that the plane of the slide shall be normal to the bench axis, and that the middles

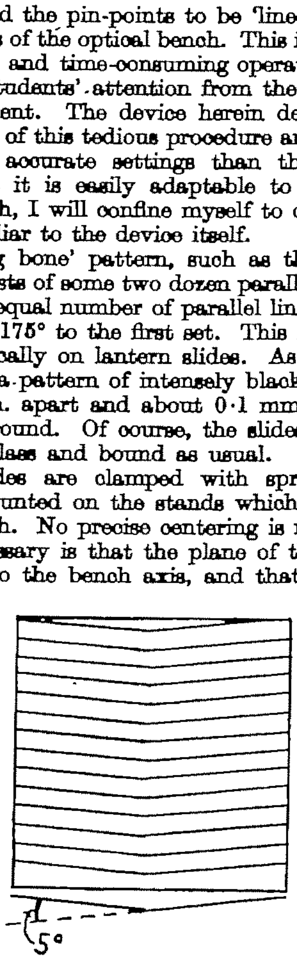

Fig. 1. Graticule pattern. The number of lines is fewer and the angle of inclination exaggerated for reasons of clarity

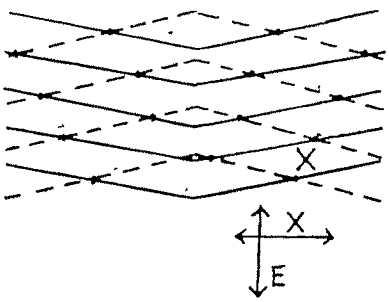

Fig. 2. Part of the pattern presented to the eye. It should be noticed that the points of the two 'herring bone' patterns do not necessarily coincide. E,X indicate the movement of the eye and the consequent sideways displacement of the intersections X

of the slides shall be roughly in line with the centre of the lens. The lens holder need not be adjustable; simple V-blocks are sufficient.

One of these slides is illuminated from behind by diffused light, and a real inverted image of its pattern is found by the lens under test in the vicinity of the other (graticule). On looking at this second graticule in the direction of the lens, the pattern of the image and the graticule appears somewhat like Fig. 2, where the dotted lines represent the image and the full lines the graticule. If the image is not in the same plane as the graticule, slight transverse movements of the eye cause the intersections (X) to shift sideways. The graticule is then moved along the bench towards or away from this position until this shifting effect disappears. The image is now in the plane of the graticule. The lines are inclined at an angle, and it is easy to show that the lateral shift of an intersection X is greater than the lateral 'parallax' displacement observed in the ordinary way in the ratio $1/a$, where a is the acute angle in radians between the two sets of lines. Thus, in our case the ratio is about $57°/5° = 11 : 1$. Thus the sensitivity is about tenfold greater than that of the older method.

When measuring the focal length of a concave mirror, or fixing the focal point of a lens system using a plane mirror behind the lens, one half of the screen is illuminated and the setting made by viewing the (reflected) image on the other half. The pattern viewed is then similar to that described.

The device lends itself to the study of the curvature of the image, to spherical aberration and to other effects. Its main advantages are its sensitivity and ease of adjustment, and that it enables a form of optical bench to be constructed which, although inexpensive, is capable of considerable accuracy.

Occurrence of *Culex simpsoni* in Mauritius

DURING a survey of breeding sites, a mosquito new to Mauritius has been found. Larvæ of *Culex simpsoni* Theobald were found breeding profusely in rock-pools in the river bed of the Tamarin Gorges. In the same pool, larvæ of *Anopheles gambiae*, *Anopheles maculipalpis* and *Culex tritaeniorhyncus* were also found. The pool was fed by seepage from a spring on the side of the gorge.

MacGregor[1] stated that the larvæ of *C. simpsoni* were pale green in colour during life; this cannot be confirmed. The larvæ and pupæ obtained from the Tamarin Gorges were light blue in colour during life, changing to pale green at death.

C. simpsoni has not previously been reported from Mauritius; but in Rodrigues, another island of the Mascarene Group, it is a common insect. It is a moot point whether Mauritius has been invaded from Rodrigues, or whether *simpsoni* is native to Mauritius, and has remained undetected due to the unfrequented and almost inaccessible siting of its breeding place. Rodrigues is, geologically, the older island; but its limited mosquito fauna (*C. fatigans*, *Ae. aegypti*, *C. simpsoni*), when contrasted with the relative luxuriant mosquito fauna of Mauritius, would suggest that it is native to Mauritius. *C. simpsoni* has not been detected in the French island of Réunion, the third and youngest island of the Mascarene Group.

It is of interest to note that the surface of the breeding pool supported both *Symphypleona* and *Arthropleona* of the order *Collembola*—an order of insects not previously recorded from Mauritius.

Paper Chromatography of Organic Acids

GLYCONIC acids, glycaric acids and glycuronic acids and certain related hydroxy acids show a marked tendency to produce streaked spots on paper chromatograms. This may be eliminated by incorporating in the developing solvent certain organic acids such as formic acid or acetic acid[1] to suppress ionization of the carboxyl group. The developing solvents incorporating formic or acetic acid vary in composition with time, due to slow esterification of the acid when an alcohol is present; for this reason R_F values are variable. Moreover, the number of suitable acidic developing solvents is limited. In order to be able to use any developing solvent for the separation of acids, we have coated the filter paper with alginic acid. Whatman No. 1 filter paper is dipped into a 1 per cent aqueous ammonium alginate solution and after removing the excess of this solution the paper is dipped into N hydrochloric acid which causes precipitation of alginic acid. The paper so treated is washed with water or ethanol to remove excess hydrochloric acid and allowed to dry in the air.

Papers prepared in this way have been used for partition chromatography of D-mannuronic acid, D-glucuronic acid, D-galacturonic acid, citric acid, tartaric acid, succinic acid, malic acid, glycollic acid, malonic acid and various aldobiuronic acids such as O-D-glucopyranosidurono-(1 → 2)-α-D-xylopyranose isolated from chagual gum[2].

Since the papers are acidic in character, the usual acid-base indicators could not be used for detecting the acids. The alginic acid, however, did not interfere with the detection of uronic acids and certain hydroxy acids such as citric, tartaric and malic acids by the ammoniacal silver nitrate reagent. The uronic acids could also be detected on alginic acid papers by the spray reagents containing aromatic amines such as aniline, p-anisidine, etc., usually employed for locating reducing sugars.

The mono- and di-carboxylic acids which could not be detected by the silver nitrate and amine sprays were located by first spraying the papers with a 50 per cent aqueous alcoholic solution containing 5 per cent of an amine (for example, aniline or *p*-anisidine) and 5 per cent sodium nitrite, and then spraying soon afterwards with an alkaline solution of either a phenol (for example, β-naphthol) or an aromatic amine (β-naphthylamine, 6,8-disulphonic acid). The acids are located by the appearance of colours due to azo-dye formation. When these sprayed chromatograms are dry, they exhibit a strong background fluorescence upon which the dark non-fluorescing azo-dye spots could readily be detected; this is particularly noticeable when an amine is used as the coupling agent.

The acids could also be detected by making use of a browning reaction catalysed by acids. When the chromatograms are sprayed with a 50 per cent aqueous alcoholic solution containing 5 per cent of an aromatic amine (for example, aniline or *p*-anisidine) and 5 per cent of a reducing sugar (D-xylose is preferred) and heated for a short time at 125–130° C., brown spots appear wherever acids are present.

Estimation of Impurities in Liquid Chlorine by Infra-red Absorption Spectrophotometry

The method of E. R. Wright and R. A. Smith[1] for the determination of moisture in liquid chlorine by infra-red absorption spectrophotometry has been extended to include impurities that give absorption bands as far as 1,180 cm.$^{-1}$ (8·5 μ). In the range 4,000–1,180 cm.$^{-1}$, liquid chlorine is, for practical purposes, completely transparent in the infra-red. This enables the use of path-lengths a thousand times greater than normal. Certain impurities can thus be estimated to a few parts per million by this method. 1

A 5·25-cm. tantalum-clad steel pressure cel (200 lb./sq. in.) was fitted with calcium fluoride windows and 'Teflon' gaskets. This cell was designed and made by the Perkin Elmer Corporation (Norwalk, Connecticut). It was fitted with stainless-steel needle valves and a stainless-steel reservoir which enabled the cell to be filled under pressure directly from an inverted chlorine cylinder, or placed in a Dewar flask and surrounded by solid carbon dioxide for filling at atmospheric pressure. Spectra were recorded on a Perkin Elmer Model 12C single-beam instrument fitted with a calcium fluoride prism to give adequate resolution.

The concentration of impurity is given by the Beer's law relationship which (adopting the usual symbols) is as follows:

$$c = \frac{1}{El}\log\left(\frac{I_0}{I}\right)\max.$$

Using standardized conditions, the concentration in parts per million can be expressed as a constant times the optical density, which is read directly from the absorption curve.

The method has been evaluated by adding weighed amounts of the following compounds to liquid chlorine (wave numbers of absorption bands in cm.$^{-1}$ given in parentheses): chloroform (1,213), methylene chloride (1,259), hexachlorobenzene (1,348). For these compounds, and at the path-length used, this method is sensitive to approximately 5 p.p.m. with an accuracy at 50 p.p.m. of ± 10 per cent.

The method has been used for the estimation of moisture in liquid chlorine using the absorption band at 1,640 cm.$^{-1}$ which is free from interference by carbon dioxide.

This work is being submitted for publication more fully elsewhere. So far as we know, this is the first account of infra-red absorption spectrophotometry of liquid chlorine from 2,860 cm.$^{-1}$ to 1,180 cm.$^{-1}$ (3·5–8 5 μ).

The constant help and advice of F. W. Matthews of this laboratory is gratefully acknowledged, and the Perkin Elmer Corporation is thanked for the loan of the cell.

Production of Individual, Sized, Droplets by High-Voltage 'Firing' from a Micropipette

There are several satisfactory methods for the continuous production of uniform droplets. The range below 10 microns may be covered in the La Mer vapour condensation apparatus, 10 μ–1,000 μ, by the spinning disk principle, 100 μ to several millimetres by the vibrating tip, interrupted jet and micro-burette principles and 800 μ to 6–7 mm. by liquid falling by gravity from the tip of a vertical tube.

In experiments on the evaporation-rates of various airborne droplets, we wished to produce individual droplets and place them with accuracy in the field of the microscope, for example, on a 1-μ diameter wire. Of the above methods, only the last is suitable for producing individual drops; but these are much too large for our purpose. The size of drops falling by gravity from a fine tip is given with reasonable accuracy by equating the upward force of surface tension acting round the circumference of the tip to the gravitational pull at the moment of breakaway: $\pi d.T = \pi D^3 \rho g/6$, where d and D are the diameters of the tip and droplet respectively. For a 20-μ tip, the diameter of the drop which falls is still as large as 0·95 mm. The cubic relationship between d and D prohibits any further worth-while reduction in D as d is reduced to the smallest practical size.

We have found that droplets of any desired size down to about 10 μ may be 'fired' off from the tip of a micropipette by applying a momentary high voltage to the liquid. Suitable micropipettes in thin-walled glass tubing may be drawn by hand; but much greater precision, particularly in the finer sizes, is given by a 'microforge' such as Powell's microscope attachment[1]. The micropipette needle is fitted to a small glass holder which has (i) a sealed-in wire electrode passing up inside the needle to make contact with the liquid, and (ii) a small side arm for supplying pneumatic pressure to the needle from a hand-operated hypodermic syringe via a length of fine rubber tubing. A source of d.c. voltage variable between 0 and 5 kV. is required, and it is convenient to apply this to the micropipette by means of a bell-push operated relay. For mounting the micropipette in its operating position, Goldacre's arrangement[2] is convenient because of its simplicity, universal adjustment and high insulation.

When forming droplets, the procedure is to apply pneumatic pressure to the micropipette, observing the drop in a microscope fitted with a calibrated scale in the eyepiece. As the drop is formed, it tends to run back up the shaft of the pipette so that the liquid usually cannot be sucked back if the required size is exceeded; however, evaporation will quickly reduce the drop to the required diameter, with most liquids. When the drop is exactly the required size, the bell-push is operated, the drop flies off and, by trial and error setting of the micropipette, may be aimed with considerable accuracy over a distance of several centimetres. The trajectory of the charged droplet is of course strongly influenced by electrostatic fields. A 100-megohm leak to earth from the electrode ensures discharge of the holder before the next drop is formed.

A study was made of the minimum firing voltage, tip diameter and drop size for various liquids with the view of establishing a relationship between the relevant parameters; but there was too much unexplained variability in the results for this to be done. It is possible that such factors as the cleanliness of the outside of the pipette and the shape and taper of the tip may have an overriding effect. The results showed a general correlation between a slow increase in minimum firing voltage and increasing tip diameter, the former being practically independent of size of drop from a given tip. In practice, it is convenient to work at a voltage of about twice the minimum firing voltage to ensure immediate firing of the drop. There is a considerable range above the minimum firing voltage which can be used; but at too high a figure the drop is disrupted and spraying commences. Observed minimum firing voltages for various tips are: $< 10\,\mu$, 0·6–1·3 kV.; 10–20 μ, 0·8–1·4 kV.; 20–50 μ, 1·0–1·8 kV.; 50–100 μ, 1·5–3·0 kV. These figures cover all liquids, from conductors such as aqueous salt solutions to insulators such as paraffin oil. The minimum firing voltages for water may be reduced considerably below these values by coating the outer surface of the pipette with a thin film of paraffin wax.

The rule-of-thumb for pipette size is that the tip should not exceed one-third of the required droplet diameter. Micropipettes down to 1–2 μ are easily made, though blockage from foreign substances in the liquid naturally becomes a problem with such fine tubes. To minimize the tendency of the droplet to run back up the micropipette, the taper on the latter should be as small as possible. With a little practice in the control of heating, traction and position of the tube when forming the pipette in the microforge, almost parallel-sided tubes can be made.

Apart from our own requirements, other uses for individually produced droplets may be found in, for example, fuel combustion studies, applying minute quantities of toxic substances such as insecticides to specific areas on insects, the calibration of droplet detectors, etc.

It should be possible to produce droplets continuously by means of a steady liquid flow and controlled frequency voltage pulse.

Acknowledgment is made to the Chief Scientist, Ministry of Supply, for permission to publish this letter, and we are grateful to Mr. W. R. Lane for advice.

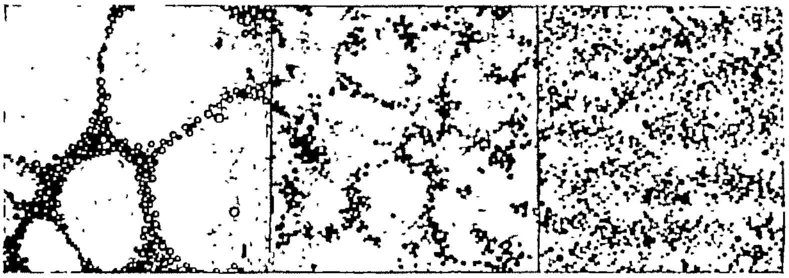
Structure of Breath Deposits on Dielectric Oils

It is possible, by low-power microscopic observation of water droplets deposited by breathing upon the surface of dielectric oils, to detect their degree of alteration by ageing.



With unused oil, the breath figures are identical with those obtained with a neutral paraffin oil containing some foreign molecules with hydrophilic groups[1]: moisture condenses on their surface as very small, randomly disposed droplets (about 10 μ in diameter). After some seconds these droplets join up, forming chains, and finally coalesce as bigger droplets located at the intersection points of former chains (Fig. 1).

With dielectric oils artificially aged (by heating for 10 hr. in contact with copper, at 120° C. or higher) droplets deposited by breathing join up as more-or-less elongated groups (Fig. 2); but they do not readily coalesce to form bigger drops.

With dielectric oil aged by being in use for a long time, the droplets do not join up at all and have the appearance shown in Fig. 3.

Determination of the Absolute Concentration of Deuterium in Thames River Water

The deuterium content of natural waters has hitherto been determined either by accurate density measurements or by a mass spectrometer, absolute values being obtained by intercomparison with standard samples of known absolute deuterium concentration prepared from deuterium-free water. However, density measurements are complicated by variations in the concentrations of the more abundant oxygen-17 and oxygen-18 isotopes, and the preparation of deuterium-free water is a long procedure. These complications can be eliminated by the following simple method, using only a mass spectrometer.

A number of standard water samples are first prepared from mixtures of the natural water and pure heavy water, giving different known excess concentrations, ΔC, above the unknown absolute concentration, C_0, of deuterium in the natural water. The values of $\Delta C/C_0$ are then directly determined by the mass spectrometer, since

$$\frac{(\mathrm{HD/H_2})\mathrm{std.}}{(\mathrm{HD/H_2})\mathrm{nat.}} = 1 + (\Delta C/C_0),$$

where both C_0 and $\Delta C \ll 1$. Hence, by plotting $\Delta C/C_0$ against ΔC, a straight line passing through the origin should be obtained, the reciprocal of the slope giving the value of C_0.

This method was used for determining the absolute concentration of deuterium in Thames water, sampled in August 1953, no previous mass spectrometer determinations having been made for any British fresh waters. Three standard water samples were prepared by weighing, using heavy water containing 99·73 ± 0·01 per cent deuterium and only 0·02 per cent oxygen-18 in excess of its natural concentration of 0·20 per cent. Gas samples were prepared from these and from natural water by reduction[1] of 25-mgm. quantities over uranium metal turnings at 500° C. The molecular isotope abundance ratio, $\mathrm{HD/H_2}$, for each of the standard samples was compared with that of the natural sample using a mass spectrometer of high stability developed from a design of Nier's[2]. The results and mean deviations are shown in Table 1 and Fig. 1.

Table 1

$C_0 = 0·0152 \pm 0·0003$ per cent deuterium

Sample	1	2	3
ΔC (per cent)	0·005800	0·01160	0·01740
$(\Delta C/C_0)$	0·384 ± 0·004	0·761 ± 0·002	1·140 ± 0·006

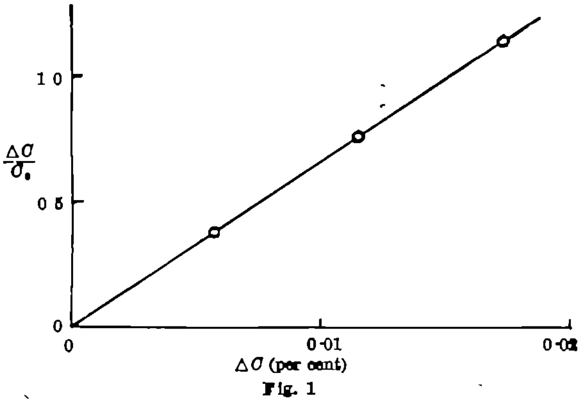

Fig. 1

The error quoted for C_0 includes the maximum possible systematic error which could have been introduced if the resistors used to measure the ion beams had not obeyed Ohm's law. Separate measurements showed that this error could not have exceeded ± 1 per cent of $\Delta C/C_0$. The normal procedure for correcting for the formation of tritium ions was used in which the effect, noted by Friedman[3], of a departure from the assumed linear relationship between the $\mathrm{HD/H_2}$ ratios and the $\mathrm{H_2}$ beam intensity at low values of the latter did not occur and was not therefore a source of error. The total measured memory effect between samples was − 1 per cent of $\Delta C/C_0$, for which the above results have been corrected.

Friedman's[3] recent survey of absolute deuterium concentrations, with a precision of ± 0·00002 per cent and absolute to within ± 0·0002 per cent, included values ranging from 0·0133–0·0154 per cent for a wide variety of American fresh waters, and 0·0153–0·0156 per cent for various ocean waters. Thus our absolute value for Thames water lies at the high end of the American freshwater range and near the less variable ocean values. This may be attributed to the fact that the bulk of the rainfall entering the Thames is only an initial condensed fraction of the water vapour carried inland by the prevailing Atlantic winds. The resulting deuterium enrichment on condensation then approximately cancels the original depletion (about 9 per cent at 10° C.) occurring on evaporation from the Atlantic, although there may be some further depletion before being carried inland. In contrast, for a large land mass like the United States, where a much higher proportion of the water vapour carried inland is ultimately condensed, freshwater concentrations extend well below the ocean values.

A Deep Sounding from the Southern Hemisphere

It is well known that the great trenches of the Western Pacific represent larger vertical departures from the level surface of the geoid than even the Himalayas. But our knowledge of the shape of the ocean floor is still so fragmentary that the question as to which trench is the deepest has received several different answers within the past two decades. The Mindanao Trench east of the Philippines was long believed to contain the greatest oceanic depth; but for a few years prior to 1950 many authorities considered that the U.S.S. *Ramapo* soundings in the Japan Trench were the deepest yet recorded. In that year Hess and Buell[1] re-examined the data and concluded that the sounding of 5,740 ± 50 fathoms obtained in the Mindanao Trench by the U.S.S. *Cape Johnson* during the Second World War represented the greatest depth. H.M.S. *Challenger* in 1951 made still deeper soundings in the Marianas Trench east of Guam. These were reported by Carruthers and Lawford[2], and later Gaskell, Swallow and Ritchie[3] stated that the maximum depth lay between 5,882 and 5,940 fathoms.

In December–January 1952–53, during the Capricorn Expedition of the Scripps Institution of Oceanography, the research vessels *Horizon* and *Spencer F. Baird* made twenty-four echo-sounding lines across the Tonga Trench between lat. 14° 30′ S. and 26° 15′ S. *Horizon* found the area of greatest depth more than 5,500 fathoms near the abrupt change in trend of the trench axis 180 miles south of the island of Tonga Tabu. In this "Horizon Deep"[4], soundings were taken by recording the echoes from explosions in order to eliminate some of the sources of absolute error inherent in the echo-sounding apparatus. Positions were determined by dead reckoning between morning and evening star sights supplemented by meridian altitudes of the sun at noon.

As the ship proceeded at about 7·5 knots, half-pound demolition blocks with 14-in. fuses were dropped overboard at 3–10 min. intervals. The charges exploded 10–13 fathoms below the surface; the firing mark and echo-train were received on the echo-sounder hydrophone and were recorded by a pen oscillograph. Timing marks were placed on the record at 1-sec. intervals using a break-circuit chronograph. The longest time of travel for the first echo was measured at lat. 23° 15·5′ S. and long. 174° 36·5′ W.

Assuming that this echo came from directly beneath the ship, and using velocities of sound at different depths computed with the aid of Kuwahara's tables[5] from temperature and salinity measurements by *Spencer F. Baird*, 200 miles north of *Horizon's* position, the time of travel corresponds to a depth of 5,814 fathoms (10,633 m.). If this were accepted as the time value, it would be the deepest sounding yet recorded from the southern hemisphere; it would exceed the Galathea Depth in the Mindanao Trench[6] by 50 fathoms and would be second only to the soundings obtained by H.M.S. *Challenger* in the Marianas Trench.

An investigation of the uncertainties involved in the depth of explosion of the charges, in reading and correcting the records, in the timing circuit of the oscillograph, and in the computed velocities of sound, indicates that the combined error from these causes is less than ± 15 fathoms. The consistency of the travel times recorded from successive explosions shows that true sea-floor echoes were obtained. But careful comparisons of the first and subsequent echoes from each shot on the line of soundings show that the first echo at the above stated position came from the relatively gentle eastern slope of the trench, and that the actual depth directly under the ship was somewhat greater. Because of the V-shaped cross-section of the trench, a 'masked' zone extended for a distance of two miles west of the position. Here the first echoes to arrive came from the steeply sloping west wall rather than from the bottom beneath. Graphical analysis of the travel times of the second echoes indicates that the deepest point actually lies near the centre of this masked zone at about 5,900 fathoms but with a rather large uncertainty. Thus the Tonga Trench may be deeper than even the Marianas Trench; measurements with a narrow beam echo-sounder are needed to resolve the question. A detailed discussion will be published shortly by one of us in the *Journal of Deep Sea Research*.

It is remarkable that all three of the greatest measured ocean depths, though recorded from widely separated areas, lie within 200 fathoms of each other in the V-shaped portions of deep trenches. This close agreement may reflect both the nature of the trench-producing forces and the strength of the earth's crust.

Bursting of Air Bubbles at the Surface of Sea Water

In recent communications, Woodcock *et al.*[1] and Knelman *et al.*[2] have described experiments in which they have studied the fragments produced by the bursting of bubbles at an air–water interface. Both groups of workers have obtained high-speed photographs of the later stages of bubble bursting which show a small jet of water being projected vertically into the air and breaking up to form a few drops. The main differences between the results of the two sets of experiments lie in the fact that whereas Knelman *et al.* used bubbles of a few millimetres diameter, Woodcock *et al.* used much smaller ones (0·2–0·02 cm. diameter) which produced much finer jets and correspondingly smaller drops. But, besides the drops produced by the jet, Knelman *et al.* also found some much smaller droplets which, they suggested, may have been produced by break-up of the bubble film. The American workers[1] report that the formation of such a group of smaller droplets was not associated with the bursting of their very small bubbles and suggest that this second mechanism occurs only in larger bubbles. It may be, of course, that the droplets produced by the disruption of very thin films are too small to be detected by normal methods, particularly as they will evaporate very quickly.

Some recent experiments I have carried out appear to throw some light on the problem. The bursting of bubbles of 0·3–4·3 mm. diameter at the surface of sea water has been studied. The mean diameter of the drops produced by a breaking jet was roughly 15 per cent of the diameter of the parent bubble. In addition to these large drops projected vertically into the air, a second group of droplets having diameters between 5 μ and 30 μ, and containing between 2×10^{-12} gm. and 5×10^{-10} gm. of salt were found several centimetres from the bursting bubble and very close to the water surface, which suggested that they were ejected at a low angle to the horizon. The numbers of these droplets were always small, a bubble of 2 mm. diameter producing, on average, only about one droplet in this size range. Similar results have been obtained by Knelman *et al.* and will soon be published.

To determine whether the disruption of the bubble film produces much larger numbers of particles too small to be detected by conventional methods, the bursting of bubbles has been studied in a cloud chamber. Clean filtered air is passed through identical jets into two chambers, one containing sea water and the other distilled water. After an equal number of bubbles has burst in each chamber an expansion is made; a dense cloud of tiny droplets is then observed in the space above the sea water but not above the distilled water. It appears that the bursting bubbles produce very small salt particles which can act afterwards as condensation nuclei during the expansion.

Bubbles of 3-mm. diameter produce 100–200 of these nuclei, the majority of which are estimated to have salt contents between 10^{-15} gm. and 2×10^{-14} gm., while smaller bubbles of only 0·5 mm. diameter burst much more violently and produce comparable numbers of nuclei. It seems entirely reasonable that these nuclei, representing the residues of droplets with diameters 0·4–1·0 μ, should be produced by the break-up of the bubble film into filaments in the manner suggested by Knelman *et al.*

The cloud chamber experiments suggest that if foam patches are largely composed of bubbles greater than 0·5 mm. diameter, disintegration of the bubble films will be a much more important mechanism for the production of salt nuclei than break-up of the jets, since the latter produce only small numbers of relatively large drops which will quickly fall back into the sea.

Linguistic Studies in Polynesia

In an article entitled "Comparative Philology and Polynesian Studies", published in *Nature* of October 10, 1953, Prof. Alan S. C. Ross points to the need of a scientific study of the Polynesian family of languages, and suggests a plan for such studies. Our purpose in commenting on Prof. Ross's article is two-fold: (1) to show that structural linguistics, the recent development of which Prof. Ross disparages, may be of help in Polynesian studies; and (2) to express a somewhat different picture of the present status of Polynesian and Malayo–Polynesian studies.

The development of structural linguistics in the past few decades may be considered a natural growth of a new science from preoccupation with purely technical collection of data, to an analysis of those data on a higher level of abstraction. Such a growth would seem to hold true of disciplines as diverse as astronomy, physics and grammar. Accurate amassing of detail no longer suffices. The desideratum is now analysis and synthesis of the data.

A good many languages have been studied by the new descriptive techniques, both of the 'exotic' variety and the well-known European ones. Each language, however, is approached with fresh eyes, with awareness of methods used elsewhere, but with realization that other descriptions cannot serve as exact models for the next language to be described.

Yet in his discussion of a method for Polynesian studies, Prof. Ross first suggests that Polynesian grammars be written on the model of ancient Indonesian, such as Old Javanese. He then rejects this idea, but without stating any reasons for his rejection. (A good reason is that only fragments of Old Javanese grammar are found in modern Hawaiian, for example). Then he proposes to eliminate grammars altogether, and "to relegate all that would be in them to the dictionaries". There seems to be a danger, however, that such a procedure would eliminate a unified approach and synthesis of the disparate phonetic and morphemic data into wholes.

Prof. Ross suggests that most structuralists are uninterested in comparative studies; yet Isidore Dyen of Yale University, who is probably the most productive Malayo–Polynesianist alive to-day, is both a descriptivist and a comparativist. At least two linguists (Robert A. Hall, jun., and George L. Trager) have insisted that the only acceptable comparative work is that which utilizes descriptive techniques at every stage, on both phonemic and morphological levels. Far from "despising" comparativism, most structuralists thus feel that with their techniques they can immeasurably advance comparative studies, or conversely, that comparative studies without revivification on each time-stage by structural analysis and synthesis are of doubtful validity.

As to the present status of Polynesian studies, we would point out that Polynesia itself is far more complex than Prof. Ross indicates. By our count there are at least twenty-three languages or dialects in Polynesia (not just five "principal" ones). For some of these there are fairly complete dictionaries; but for others the data are nearly non-existent, particularly for the 'outliers' in Melanesia, which are in particular need of study. Samuel H. Elbert has recently published a paper[1] that establishes a tentative system of sound shifts for twenty Polynesian languages or dialects, draws up a tentative family tree for sixteen of them, and suggests time dates for their separations from the central stock.

At the present time a joint research programme in the Oceanic field is being conducted by Yale University, the University of Hawaii, and the Bernice P. Bishop Museum. This programme, supported by a grant from the Carnegie Corporation, is directed toward understanding the processes of culture change that have been and still are operating in this island area, with particular reference to the Malayo–Polynesian-speaking peoples. Prof. Ross states in his article that "anthropologists rather naturally tend to regard linguistics as a subordinate subject". It is interesting to note that, although this programme is indeed anthropological, one of its initial, major efforts involves library and field research conducted by professional linguists with the aim of gaining a fuller knowledge of the historical relationships among the Malayo–Polynesian languages. Polynesian is an important concern in this effort.

Prof. Ross's suggestion of a New Zealand centre for the study of the comparative philology of Polynesian merits serious consideration. However, in view of the severe financial limitations under which universities supporting linguistic research are at present working, perhaps a more feasible approach is the furthering of co-operative endeavour among scholars and institutions everywhere with a current interest in the Pacific. There is much to be done in the Polynesian area, and all workers are welcome.

FORTHCOMING EVENTS

Sunday, September 5—Wednesday, September 8

British Association for the Advancement of Science (at Oxford).—Continuation of Annual Meeting.

Sunday, September 5

At 8 p.m.—Prof. C. A. Coulson, F.R.S.: "Science and Religion".

Monday, September 6

At 10 a.m.—Dr. C. J. Stubblefield, F.R.S.: "The Relationship of Palæontology to Stratigraphy" (Presidential Address, Section C).

At 10 a.m.—Prof. A. D. Macdonald: "The Relief of Pain" (Presidential Address, Section I).

At 8 p.m.—Dr. F. P. Bowden, F.R.S.: "Friction".

Monday, September 6—Thursday, September 9

Physical Society (at the Cavendish Laboratory, Cambridge). Conference on "The Physics of the Ionosphere".

Monday, September 6—Tuesday, September 14

Institute of Metals (in Switzerland).—Forty-sixth Annual Autumn Meeting.

Tuesday, September 7—Tuesday, September 14

British Mycological Society (centred on the University of Southampton).—Autumn Foray, 1954—New Forest, Hampshire.

Thursday, September 9—Monday, September 13

Textile Institute (at Ghent).—Conference on "Fibre Friction".

APPOINTMENTS VACANT

Applications are invited for the following appointments on or before the dates mentioned:

Physicist (with a good honours degree in physics, and at least two or three years research experience, and preferably some practical acquaintance with electronics), to work under the Professor of Laryngology and Otology in the field of psycho- and physio-acoustics—The Secretary, Institute of Laryngology and Otology, 330–332 Grays Inn Road, London, W.C.1 (September 10).

Scientific Officer (with a first- or second-class honours degree in physics or mathematics, and an interest in applying mathematics to practical problems), to carry out theoretical work in connexion with the design of nuclear reactors—The Establishments Officer, Atomic Energy Research Establishment, Harwell, Berks, quoting 2/108/189 (September 10).

Assistant Biochemist (with a degree or equivalent qualification in chemistry, and wishing to take up clinical biochemistry)—The Secretary, Welsh National School of Medicine, 34, Newport Road, Cardiff (September 11).

Lecturer (with teaching experience, and a special knowledge of the theory and operation of electrical machinery) in Electrical Engineering—The Secretary of University Court, The University, Glasgow (September 11)

Lecturer (graduate in medicine) in Physiology—The Assistant Registrar, The Medical School, The University, Birmingham 15 (September 17).

Assistant Sylviculturist (with a degree in forestry, and preferably with practical experience in sylvicultural research and biometry) in the Wattle Research Institute of the University of Natal, Pietermaritzburg—The Secretary, Association of Universities of the British Commonwealth, 5 Gordon Square, London, W.C.1 (September 30).

Lecturer or Assistant Lecturer in Histology and Embryology in the Department of Veterinary Anatomy—The Secretary, Royal Veterinary College and Hospital, Royal College Street, London, N.W.1 (September 30).

Lecturer or Junior Lecturer in Sociology at Rhodes University, Grahamstown, South Africa—The Secretary, Association of Universities of the British Commonwealth, 5 Gordon Square, London, W.C.1 (South Africa, September 30).

Lecturer (with a degree in electrical engineering, preferably with honours, and a knowledge of the theory of automatic control) in Electrical Engineering, at the New South Wales University of Technology, Sydney—The Agent-General for New South Wales, 56–57 Strand, London, W.C.2 (October 15).

Chair of Mechanical Engineering in the New South Wales University of Technology, Sydney—The Agent-General for New South Wales, 56–57 Strand, London, W.C.2.

Chemist (with a first- or second-class honours degree in chemistry, and preferably with some experience of plant biochemistry), to work on nutritional disorders of glasshouse crops—The Secretary, Experimental and Research Station, Cheshunt, Herts.

Chemist (with an honours degree of a British university in chemistry, and/or Associate or Fellow of the R.I.C., and with three years postgraduate experience) in the Medical Department, Hong Kong, to assist the Government Chemist in analytical and consulting work concerned with public health; control of narcotic drugs; strategic materials; dangerous cargoes; commercial analytical work; toxicology, etc.—The Director of Recruitment, Colonial Office, Great Smith Street, London, S.W.1, quoting BCD/117/51/108.

Microbiologist (with biochemical training) for research on the anaerobic fermentation of cellulose-rich materials; a Biochemist (with training in plant physiology and microbiology) for research on the biochemistry of nitrogen fixation in nodules on leguminous plants; and a Microbiologist (preferably with mycological training), for research on the effects of antiseptics on the soil microflora—The Secretary, Rothamsted Experimental Station, Harpenden, Herts.

Mining Geologist (with a B.Sc. degree with honours in mining geology) in the Colonial Geological Survey Service, Sierra Leone, for duties which include search for new mineral deposits, mapping, petrology and mineralogy of known mineral deposits, geological mapping, and geophysical prospecting by resistivity and magnetometry—The Director of Recruitment, Colonial Office, Great Smith Street, London, S.W.1, quoting BCD 105/15/02

Physical Chemist (with a good honours degree, and preferably with research experience) in the Colloid Chemistry Section—The Director of Research, British Rubber Producers' Research Association, 48 Tewin Road, Welwyn Garden City, Herts.

Physicist (Ph.D. or equivalent status, with experience in vacuum technique), for development and control of freeze-drying of biological subjects—The Director, Wellcome Research Laboratories, Langley Court, Beckenham, Kent.

Research Assistant (graduate in physics or electrical engineering, and interested in the technical problems of nuclear particle accelerations) in Physics—The Registrar, The University, Birmingham 15.

Research Physicists and Electronic Engineers (with first-class qualifications and experience), with the European Council for Nuclear Research, Geneva, to assist in the design and construction of high-energy accelerating machines for nuclear research—The Secretary, Ministry of Labour and National Service, Almack House, 26 King Street, London, S.W.1, quoting AS.12/CERN

DEVELOPMENT OF ATOMIC ENERGY IN BRITAIN

THE transfer to the Atomic Energy Authority on August 1 of the ownership of Britain's atomic factories is something more than a formal change of name and responsibilities. The powers and functions of the new Authority differ from those of the Ministry of Supply under the Atomic Energy Act of 1946, and although the public authority set up under the Atomic Energy Authority Act, which received the Royal assent on June 4, takes over all the atomic plants of the country, a nationalized atomic energy industry was not thereby created. The money to operate the plants will be voted annually by Parliament—the revised estimate for the current year is £53·7 million, of which nearly £27 million is for new plant and buildings—and there is every intention of encouraging industry to play as large a part as possible in the development of atomic resources. Moreover, the far-reaching powers for the control of the production and use of atomic materials formerly possessed by the Ministry of Supply have been transferred to the Lord President of the Council and not to the new Authority, nor is it assumed that the latter should possess a *de facto* monopoly of new knowledge in this field.

The significance of the transfer is well put in a recent article in *The Economist* (July 31). The important clauses in the Act from this point of view are those which open the way to what it is hoped will become increasingly close co-operation with industry and permit any nuclear process—such as the generation of power for electricity or transport, the production of plutonium (with electric power as a probable by-product) or chemical processes based on nuclear reactions—to be undertaken legally by private industry, unless expressly forbidden by the Lord President of the Council. Still more is it to be seen in the light of the prospects to which Sir Francis Simon referred in a lecture early this year (see *Nature*, 173, 573; 1954) and on which Sir John Cockcroft touched in addressing the scientific committee of the French Chamber of Deputies in Paris on July 1. Mr. Geoffrey Lloyd's remarks in the House of Commons on July 9, in moving the second reading of the Gas and Electricity (Borrowing Powers) Bill, and the creation by the British Electricity Authority of the new post of nuclear power engineer, are also significant.

The Atomic Energy Authority is empowered by the Act to provide technical training and distribute information, to sub-contract research to university or industrial laboratories, and to make grants to assist the independent production or use of atomic energy, as well as to aid atomic research. Such industrial co-operation will obviously take time to develop, and this greater freedom for the exchange of knowledge and technique should enable the atomic scientists of the Authority, on one hand, to consider how atomic energy could be applied in different industrial fields, and to acquire specialized knowledge of engineering design and operating technique, while industry, on the other, will be enabled to acquire first-hand knowledge of the physical problems of making and handling fissile materials. Such contact and discussions may, in the first instance, be limited to the design of plant for specific problems, but should lead ultimately to the design and construction of nuclear equipment by industry itself. In particular, an impetus should be given to the fuller investigation of nuclear chemistry where, as Lord Cherwell emphasized in his Messel Memorial Lecture on July 14, our knowledge is at present so rudimentary.

The development of the most satisfactory way of establishing effective liaison with industry and of resolving the many practical problems, of which security is only one, will take time, however urgently and sympathetically it may be fostered by the Board of the Authority. Moreover, the field in which it is likely to be developed first, that of power production for the British Electricity Authority, is now visualized as much nearer than was generally anticipated a few years ago. Sir John Cockcroft said in Paris that, at present prices of raw materials and on present estimates of capital costs, the atomic power plants now being built in Britain would be able to supply electricity at about a penny a unit, compared with about three farthings a unit from the most modern coal- or oil-burning stations. These power stations, such as that at Calder Hill, Cumberland, which is expected to come into operation in 1956, are essentially experimental. By the time the scientists and engineers are ready to hand over the building or operating of such power plants to the British Electricity Authority, as contemplated under the Act, improvements in production methods or design, and particularly the efficiency with which uranium is used, should have reduced costs still further.

Sir John Cockcroft emphasized that this provisional cost of one penny a unit is only possible because the by-product, plutonium, is used. That is a reminder that the use of atomic power cannot be sharply divided between specifically military and specifically civilian use; but for Great Britain this nearer prospect of the industrial application of nuclear power is important in another connexion. The six-year plan for the development of fuel and power which, in effect, the Minister of Fuel and Power outlined in his speech on July 9 and, in part, was earlier described by the British Electricity Authority in a pamphlet, "Power and Prosperity", published last February, contemplates the design and construction of nuclear power stations of an advanced type by 1960, in preparation for which the British Electricity Authority was establishing a nuclear power branch of its engineering department. Sir John Cockcroft had outlined a programme in which the detailed planning and construction of two experimental nuclear power stations to supply electricity to the grid on a commercial basis would occupy eight years, until 1962. After trial operation for three years, the large-scale construction of nuclear stations to supply the major part of our power requirements would follow during 1965–70.

The important consideration, however, is not simply that Mr. Lloyd's proposals visualize an earlier contribution from nuclear power, but rather the extent to which his plan involves demands on our resources of coal and other materials as well as man-power. Besides its attention to nuclear power developments, the British Electricity Authority is pushing ahead with a programme for the expenditure of £750 millions on the construction of conventional power stations, some of which will experiment with oil in order to save coal. Nevertheless, in spite of improvements in efficiency which are estimated to save six million tons of coal a year, these plans envisage the consumption of an additional fourteen million tons of coal a year for the generation of electricity and a further two millions for the production of gas. The total investment of coal, gas and electricity between now and 1960 will amount to £2,250 millions.

In considering the economics of the distribution of the nation's resources in this way, there is a further factor which both Sir John Cockcroft's estimate and Mr. Lloyd's proposals neglect. The price of coal to-day does not represent its scarcity to the nation, and in assessing the national advantage of coal-saving investment, a higher price for coal should be assumed. Indeed, it has been computed that if nuclear power could be produced to-day, it would be cheaper to the nation by a factor of ten or twenty per cent than that produced from coal. Disregarding the economic value of the plutonium by-product, to which Sir John Cockcroft referred, and the security or defence implications, it seems probable that although the initial capital cost of a nuclear power station is very much higher than that of an equivalent conventional station, by the time such a station could be brought into operation, technical and economic developments would give nuclear power very considerable economic advantages.

In assessing the claims upon the nation's resources—for investment, materials or man-power—of nuclear power development and of the plans outlined by the Minister of Fuel and Power, there is a further consideration. Nuclear power developments must not be pressed too hard, because of the risk of expensive technical mistakes. Even on Mr. Lloyd's more optimistic estimate, however, it seems probable that economically the new power plants contemplated by the British Electricity Authority may be obsolescent almost as soon as they are built. The decision as to the apportionment of capital resources cannot be easy; but some more comprehensive statement of the Government's plans seems desirable.

Hitherto, the recommendations of the Ridley Committee have been virtually ignored; but in the position now disclosed, it seems essential that between now and 1960 a main objective of policy should be to reduce the consumption of coal to the minimum possible. Alternatives such as water-power and natural gas should be exploited as far as possible where available; but Sir Cyril Hinshelwood's words in the annual report of the Fuel Research Board for 1953 go to the root of the matter: "On the basis of existing knowledge, and with no undue capital expenditure, the same amount of useful heat and power as is now obtained could be achieved with a saving over the country as a whole of several million tons of coal a year. Better still, for the same total fuel consumption there could be greater industrial productivity and improved conditions of comfort. With further intensification of fundamental and applied research, ways and means could be found for obtaining even greater fuel and power efficiency at an economic cost justified by the potential savings". No plan for the development of fuel and power which ignores this aspect can be regarded as realistic, and support for the programme outlined by the Minister for Fuel and Power must wait on evidence that it represents the minimum demands which can reasonably be made on Britain's resources of coal, manpower, capital and other raw materials.

GOVERNMENT AND SCIENCE

Government and Science

Their Dynamic Relation in American Democracy. By Don K. Price. (James Stokes Lectureship on Politics. New York University–Stokes Foundation.) Pp. ix+203. (New York: New York University Press, 1954.) 3·75 dollars.

In the first four chapters of this book Mr. Price traces the development of science in the United States and the way in which the form taken by its organization was shaped, inevitably, by the pattern of American institutions and democratic ideas. In them he epitomizes also much to be found in those earlier reports, "Research, a National Resource", in Dr. Vannevar Bush's "Science, the Endless Frontier", and the Steelman Report, "Science and Public Policy", and he gives the gist of the debate which ultimately issued in the establishment of the National Science Foundation. His shrewd comments and penetrating analysis of the real issues contribute to a clear understanding of the difficulties which the latter Foundation has hitherto encountered. They will also help those outside the United States to appreciate more fully what lies behind the security problem in that country, and the way in which it has affected scientists. Although Mr. Price writes with his eyes on the American scene and reader and his comments on the British practice and organization are sometimes uncertain and not always entirely accurate, these chapters will be read with interest by all who to-day are concerned with the problem of securing the adequate endowment of scientific research without external control, or with the other main problem of the relations between Government and science, namely, that of determining how best the findings of science can be integrated into public policy where required.

It is, however, the chapters on the "Machinery of Advice" and the "Structure of Policy" that give the book its widest appeal. As an exposition of the issues involved in the place and use of the expert in government, be that expert administrator or scientist, they can scarcely be bettered. Mr. Price goes right to the heart of the problem, and the principles he lays bare are as valid and relevant in Great Britain and elsewhere as in the United States. What he has to say on the vulnerability of science to political attack, or on the consequences that follow when scientists best able to exercise discriminating judgment on matters of secrecy and security are by temperament and tradition so impatient that they leave this too much to people who know too little abo applies on both sides of the Atlantic. The c between scientific freedom on one hand and security considerations on the other, as he points out, may really be due not to a fundamental conflict, but simply to political irresponsibility or sheer incompetence. Mr. Price reveals the complexities of the situation and the dangers which promptly follow failure to recognize where the boundaries of knowledge end and the realm of responsible judgment begins. Nor does he suggest that we are likely to find an easy solution. The lines of advance that he indicates can be as usefully pursued in the context of conditions in Great Britain as in the United States. Though the particular solution found will vary, certainly in detail, and quite possibly considerably in structure, it will doubtless be found that in both countries success will depend more and more on our administrators and perhaps some of our political leaders beginning their careers as scientists, or at least with some training in science.

The book can be whole-heartedly commended to all who are concerned with the problems which the advancement of science involves for society, and the way in which public policy could be based on knowledge as far as is possible. Even for its last chapter alone it is worth reading, and the pity is that so outstanding a book should have been produced without either index or bibliography. R. Brightman

THE CAMBRIDGE PLATONISTS

The Platonic Renaissance in England

By Prof. Ernst Cassirer. Translated by James P. Pettegrove. Pp. vii+207. (Edinburgh and London: Thomas Nelson and Sons, Ltd., 1953.) 15s. net.

The British genius for understatement is well illustrated in this very able translation of the late Prof. Ernst Cassirer's book, originally published in German in 1932. For not only has it been left to a distinguished Continental scholar (an expert in Neo-Kantianism) to portray the Cambridge Platonists as they should be portrayed, but even among professionals in Britain they have been put on one side. There are reasons for this neglect, which will appear in the sequel; meanwhile, a little more enterprise over—say—the past two centuries would have given weight to these scholars' limitations, while extracting the essence of their thought. Nevertheless, in the pages before us, there is now a good 'yield'. But the remarkable thing is how relevant to our present intellectual position these essays are: they could scarcely be more appropriate if they had been contributed *ad hoc* instead of as a commentary upon a group of seventeenth-century thinkers, themselves not always lucid in analysis, and deplorably prolix in expression. Yet, they had a 'message' for mankind.

To see what this was, it is necessary to appreciate the philosophical climate in which these Cambridge men, Henry More, Ralph Cudworth, Benjamin Whichcote and John Smith, laboured. It was the age of empiricism and of Puritanism. At first sight, these somewhat chilling winds would appear to blow in opposite directions (and so perhaps to cancel out); but on closer reflexion they are seen largely to reinforce one another, and thus to produce a mighty blast against which these Platonists struggled man-fully, ill-equipped as they were in some respects for so stiff an encounter.

Stripped of all its frills, Francis Bacon, Thomas Hobbes and John Calvin had evolved between them a theory of knowledge which said in effect, "Power is what matters; power over Nature and power over men". Acts of cognition not directed specifically to these ends were classified as futile, if not worse. Investigation, on this view, was not justified if it produced mere understanding; its proper purpose was almost judicial, to force a witness to depose, and to use the information to gain the mastery. In brief, empiricism and pre-destination were birds of a feather. Against all this, with such imperfect weapons as they possessed, the men of Cambridge waged unending warfare. They wished to contemplate rather than to impose, to enjoy the secrets of Nature rather than to debase them by making them but tools in the service of a particular type of political philosophy. In effect, they were gentle, antiquarian and basically opposed to the prevailing spirit of progress. When one recollects the characteristic self-confidence of the age, there emerges a deep respect for these lonely savants, paddling about in a little backwater, but at the same time keeping afloat a liberty, a magnanimity and a humility, all in danger of becoming submerged in a lust for power.

But they did more than that. As later generations have discovered, there is no sure sense of the beautiful without contemplation. From seventeenth-century Cambridge, therefore, emerged the bare bones of æsthetics as we now know it, though it was not to be called by such a name until the following century had run half its course; and in between, the Society of Antiquaries was founded, to study the past, rather than to obliterate all traces of it.

Thus, much of what Prof. Cassirer has to say redounds to the credit of that post-Reformation foundation, Emmanuel College, Cambridge, to which the majority of these writers belonged. (Incidentally, there is a sizeable corpus of Cudworth's scripts still not printed.) Brought up, for the most part, in surroundings of ecclesiastical rigour, they cast off many of its more unlovely fetters, and managed to combine the Puritan ideal of service with a fair zest for life. Above all, they knew what they wanted, and, as Prof. Cassirer points out, never was the adjective 'latitudinarian' more inappropriate than when applied to Cambridge Platonism.

We now come to a peculiar feature of the movement, and of the niche which it must always occupy in the history of thought. This is the way in which it regarded the natural sciences. Strange to say, Henry More in particular was very keen on experimental philosophy as it was in his day. His distrust of the empiric did not inhibit this activity in the least. But unfortunately his critical faculty deserted him. He would assemble fact after fact, with no attempt to discover any unifying principle. Added to which, a somewhat facile regard for miracles and the like brought confusion and negation just when clarity was most needed. Ill-equipped in mathematics, and deficient in epistemological judgment, the Cambridge School presented to a hostile world the paradox of a nexus of men zealous for the enthronement of reason in matters of religion, while abandoning it entirely in the sphere of science.

On more than one occasion, pioneers have been known to work in a vacuum, with the result that no contact with the outside world could occur until, by chance, an interpreter appeared, ready and willing to be their spokesman, and so to save them from public oblivion; and so it turned out to be for the Cambridge Platonists, when their labours attracted the attention of the third Earl of Shaftesbury (1671–1713). He identified himself with their doctrines and introduced them to a far wider circle than they would otherwise ever have reached. At the same time, he made secure their system of ethics, and of æsthetics, by supporting the essential liberty of mankind both against 'sanctions' and spurious rewards. It must have needed some courage to achieve this, for one who had been a pupil of John Locke, and was afterwards his patron.

Prof. Cassirer has done the cause of the Cambridge Platonists a distinct service by writing his book in the first instance. By producing this translation, however, Dr. J. P. Pettegrove and the publishers have performed a valuable auxiliary task, which should enable students of English-speaking countries to judge for themselves how deeply our present-day outlook has been influenced by the unfashionable efforts of these seventeenth-century scholars.

F. I. G. RAWLINS

THE NUCLEIC ACIDS

The Biochemistry of the Nucleic Acids

By Prof. J. N. Davidson. Second edition, revised. (Methuen's Monographs on Biochemical Subjects.) Pp. viii+200+4 plates. (London: Methuen and Co., Ltd.; New York: John Wiley and Sons, Inc., 1954.) 10*s*. 6*d*. net.

ALTHOUGH the nucleic acids have been investigated for more than eighty years, it is only comparatively recently that their true biological importance has been appreciated. Early work in the old tradition of organic chemistry appeared to have established that the nucleic acids were simple in structure and probably only two in number, and, as a consequence of this, there was little incentive to study the nucleic acids from the point of view of their possible biological specificity. This is the state of relative stagnation which is reflected in the classical monograph of Levene and Bass, published in 1931. For years following this, work on the nucleic acids was largely confined to observation of the quantities present in various tissues, both from a macroscopic and a microscopic point of view.

In 1944, however, the phenomenon of pneumococcal transformation was discovered by Avery, McLeod and McCarty to be due to a deoxyribonucleic acid, an observation suggesting that, in fact, the nucleic acids did have biological specificity of a high order. A structural basis for this followed a few years later, when chromatographic analysis revealed that the nucleic acids are not only very complex in structure, but are also very numerous and varied in composition according to their source. Since that time many instances of nucleic acids possessing biological specificity have been discovered, and this has revolutionized the whole approach to the subject.

Progress in the field is at the moment extremely rapid, and it is inevitable that any book covering the subject will be out of date in some respects. The second edition of Prof. J. N. Davidson's monograph, however, covers most of the recent developments, much of the text having been rewritten, and a number of errors and omissions in the first edition have been rectified. It is remarkable how many of the references are to papers published since the first edition of this book, and the author is to be congratulated on the wide field which he has covered. There are, perhaps, places where the old has not given due place to the new. For example, although the recent structures, based upon the X-ray work done in King's College, London, are mentioned, considerable space is devoted to a minute examination of work which these investigations have made obsolete. Again, Fig. 6.3 may convey little to those unfamiliar with the theory underlying microspectrophotometry, while to students of instrumentation it will appear delightfully old-fashioned.

A minor criticism is that the space devoted to the work being done on the nucleic acids of micro-organisms is rather restricted, because it is in this field that the most exciting recent developments have appeared. The work of Hershey and his colleagues is of such fundamental importance that it deserves to be dealt with at length, while the related and most exciting subject of bacterial transduction is not mentioned. In fairness it should be stated that this is one of the few omissions in an excellent and inexpensive text-book, and it will, no doubt, be remedied in the next edition, for there will certainly be a next edition.

The references are now grouped at the end of each chapter, an alteration which is a great improvement on the arrangement in the first edition, because this book, while covering the subject adequately for the general reader, will also be found to be an excellent guide to further reading. ROY MARKHAM

SUPERCONDUCTIVITY

Superconductivity

By Dr. D. Shoenberg. Second edition. Pp. x+256. (Cambridge Monographs on Physics.) (Cambridge: At the University Press, 1952.) 30*s*. net.

MORE than forty years have now elapsed since Kamerlingh Onnes discovered superconductivity; but in spite of the large volume of experimental material which has since come to hand, the phenomenon remains as enigmatic as ever. Indeed, all recent attempts at theoretical explanation have served to emphasize the difficulties which stand in the way of a satisfactory explanation. Of late, and particularly since the War, the number of cryogenic laboratories has greatly increased and a new generation of low-temperature physicists has grown up. To them much of the experimental work on superconductivity is historical fact rather than personal experience. The new edition of Dr. Shoenberg's book is therefore a most welcome aid for all working in the field and in particular for those students who wish to specialize in low-temperature research.

The first edition of the book, published in 1938, had become the standard work of reference on the subject of superconductivity; but the rapid growth of the subject has necessitated re-writing rather than a revision. This is best shown by the increase to more than twice the volume of the first edition. The lay-out of the book, too, has been somewhat changed to allow a better grouping of the subject-matter.

The introduction, which briefly lists the essential facts of superconductivity, is followed by a chapter on the magnetic properties of macroscopic superconductors. These and the subsequent chapter on the thermal properties roughly follow the lines of the first edition with the inclusion, however, of many new results and with some more detailed treatment of the old material. The new survey of the work on heat conductivity and thermo-electric effects will be especially noted. The separate chapter on alloys at the end of the first edition has now been incorporated in the general discussion of macroscopic magnetic effects, with a short mention of their thermal properties under the respective headings.

The next two chapters on the intermediate state and on the penetration of a magnetic field into the surface of a superconductor are quite new. These researches had only just been started at the time of the first edition, and it is here where most of the experimental progress has been made. A good deal of this progress is due to Dr. Shoenberg's own work. Writing with this unique qualification, he has produced a well-balanced and extremely clear account of a difficult and somewhat involved subject. Also new is the final chapter, on the theoretical aspects. The main emphasis is placed on the phenomenological theories of F. and H. London and on the two-fluid model of Gorter and Casimir, while the 'fundamental' theories of Heisenberg and of Fröhlich and Bardeen are briefly discussed in the closing paragraph. Considering the rudimentary state of these latter attempts and the success of the phenomenological models, this choice of emphasis must appear, at the present state of affairs at least, fully justified. Where one may perhaps not follow the author quite so whole-heartedly is in his optimism regarding a speedy solution of the fundamental problems and in his enthusiasm for the latest refinements of the phenomenological treatment. However, this should be regarded as a difference in temperament rather than as a serious criticism of the book.

It is rare for a reviewer to find so little fault with a book and to be able to recommend it so fully as in the present case. Whether one wishes a student to familiarize himself with the subject, or whether one wants to refer to a particular point in the discussion of research, Dr. Shoenberg's book will prove equally useful. Whether one looks at the text, or the data in the appendix, or the references to original work, the same care and competence is everywhere apparent. It will be indispensable to anyone dealing with the subject of superconductivity.

K. MENDELSSOHN

PHYSIOLOGY OR META-PHYSIOLOGY?

Chemical Physiology of Contraction in Body and Heart Muscle

By A. Szent-Györgyi. Pp. xx+135+3 plates. (New York: Academic Press, Inc.; London: Academic Books, Ltd., 1953.) 4.80 dollars.

PROF. A. SZENT-GYÖRGYI, in the foreword to his latest book on muscle, says that he will "try to tie the facts together" and "talk in a language understandable to the average biologist, stressing outlines more than details". The average biologist, however, will need to be extremely alert to distinguish "facts" from "outlines" and vice versa; for the author is prolific in speculations which are built very skilfully, one upon the other. This discursive way of writing has the virtue of stimulating the reader acquainted with the fundamental data; but it is liable to lead others less knowledgeable into a veritable no-man's-land of hypotheses which William of Occam says should not be multiplied beyond necessity.

The book is divided into three parts. Part 1 opens with a discussion of the structure of myosin in terms of the sub-units, L- and H-meromyosin, obtained by short digestion of myosin with trypsin. The heavier of the two (H) possesses the adenosine triphosphatase activity and actin-combining ability of the parent molecule, where the lighter (L) is held to be responsible for the contractile properties of the actin–myosin system. On the basis of these findings, it is deduced that the intact myosin molecule is made up of two terminal H-units linked covalently to four L's in series; but, although the arithmetic by which this conclusion is reached is sound in itself, it cannot be considered proved in the absence of accurate data on the degree of hydration and the relative proportions of the two components. Nevertheless, this structure is used as the cornerstone in erecting the far more elaborate edifice of the protofibril. Again, the arithmetic is without blemish.

The structure of the protofibril established, the author proceeds to dilate on its contractile properties in terms of 'autones', hypothetical subunits of actomyosin which react with one molecule of adenosine triphosphate only. Relaxation is treated first, in terms of the recent finding that muscle-fibre models will relax in the presence of adenosine triphosphate, creatine phosphate, magnesium ions and an enzyme capable of transferring phosphate from creatine phosphate to adenosine diphosphate. In this system relaxation occurs only if the *p*H is below 6·5; above this *p*H the fibres contract, and this also occurs on addition of calcium ions. Without more ado it is assumed that this system operates *in vivo*, although the necessary changes in *p*H in the buffered system of intact muscle would require an amount of acid or base very much larger than that suggested by the author. Moreover, an alternative has already been proposed by Marsh, who discovered a factor which induced relaxation in the presence of adenosine triphosphate only, without the intervention of a large change of *p*H or of creatine phosphate. The properties of this factor have lately been confirmed by Weber and by the present reviewer.

It is implicit in Szent-Gyorgyi's scheme of relaxation that adenosine triphosphate should be split to adenosine diphosphate during contraction, since otherwise creatine phosphate would be without effect. However, in a later chapter, splitting is considered to occur only in the phase of relaxation, whereas the energy for contraction is imparted as free energy by the adenosine triphosphate molecule without change in its structure. The meaning of this concept is not clear and, moreover, appears to conflict with Weber's findings that splitting and contraction go hand in hand, whereas relaxation occurs only when splitting is inhibited—for example, by salyrgan or by the Marsh factor. Again, it is evidently considered that this transfer of free energy is an endothermic process, whereas Hill has shown conclusively that contraction is entirely exothermic, as would also be expected from Weber's findings.

Part 2, a study of heart muscle, mainly describes the 'staircase' effect and the action of various substances upon it. Many of the findings are well known. As intact heart muscle is used, the added substances must exert their effect primarily on the cell membrane and not directly on the contractile proteins, as is the case with glycerinated psoas-muscle fibres. For this reason, it does not seem possible or profitable to compare the two systems directly.

Part 3 is entitled "Interpretations" and includes some new speculations on the nature of the conduction of the nervous impulse. It is noteworthy that the 'continuum theory' of muscle, which was a prominent feature of the author's earlier books, has been omitted entirely here.

The book contains several typographical errors, of which the most glaring is the use of the words 'isometric shortening' when 'isotonic' is clearly intended (pp. 55–56). In conclusion, the student and the 'average biologist' should again be warned that, although the book is fascinating and forthright in its statements, it 'ties together' only a limited number of facts and fails to take into account much important work by other schools; as the author himself says, it is certainly not a comprehensive and exhaustive review.

J. R. BENDALL

AN ITALIAN TEXT-BOOK OF ZOOLOGY

Trattato di Zoologia

Da Umberto D'Ancona. Pp. xxiv+1102+1191 Figs. (Torino: Unione Typografico-Editrice Torinese, 1953.) 10,500 lire.

THIS text-book is intended to meet the requirements of a two-year university course in zoology for students in natural science. It is divided into two quite separate parts. The first part (pp. 1–438), subdivided into five sections, is a general introduction to animal function in its widest sense. It starts with a short definition of the science and its main branches and then gives an epitome of its history from classical to modern times. The second section treats of living matter and vital functions, and while, in a way, this is based on cytology, it must be understood that it includes the physical, chemical and physiological activities of protoplasm. The third section deals with the functional organization of the animal body, and here again, while histology and early embryology play an essential part, the functional and comparative aspects are stressed. Thus, under light perception, we find discussed the eyes of Turbellaria, a gastropod, *Nautilus* and a "higher cephalopod", an insect and a teleost. Section 4 is concerned with genetics and evolution, the various aspects of which are dealt with adequately for the non-specialist. The last section discusses the relationships of animals to the world and to one another, ecology, zoogeography, applied zoology, migration and human industries based on animals, etc.

The second part (pp. 441–1019) is a survey of the classification of the animal kingdom in a formal, group-by-group manner. Then follow a full bibliography, author index and subject index (pp. 1049–1102). Possibly the first thing that would strike a reader in Great Britain familiar with the traditional text-book is the almost entire absence of comparative anatomy. Under mammals, for example, there is the diagram of the alimentary canal of a herbivore (with no buccal cavity), a diagram of the heart of a mammal, and again another of the male reproductive organs. Nowhere does the student get an overall picture of any one of the higher animals, and the diagrams just mentioned are not based on any particular animal but are purely schematic. There are some curious omissions; for example, while *Latimeria* is illustrated, there is no reference to the work of Stensio and his school, so essential to an understanding of the early fishes, and there is no mention of the pre- and exo-erythrocytic stages of the malarial parasite necessary to the comprehension of the disease.

It is possible to find slips and errors; but for one author to have accomplished so exacting a task is a matter for congratulation, and any reader will be struck by the large amount of information it contains. The illustrations are all good, but some deserve special notice; these are a number of original figures of fishes and a number of very pleasing sketches of living marine animals made in the Naples aquarium.

TEXT-BOOK OF BIOCHEMISTRY

Textbook of Biochemistry

By Prof. Edward Staunton West and Prof. Wilbert R. Todd. Pp. x+1,345. (New York: The Macmillan Company, 1951.) 90*s.* net.

THIS text-book will be welcomed by many teachers who have sought a comprehensive modern treatise suited to the needs of students taking an advanced course in biochemistry. Its most outstanding feature is the amount of detailed experimental evidence which the authors give throughout the book. This is particularly well done in the chapters on intermediary metabolism, which provide a very adequate and balanced account of this intricate subject. It is apparent that the authors have made every effort to bring this section up to date, even to the extent of inserting several pages on coenzyme A after the rest of the book had been printed. In a few of the earlier chapters, the information is obviously of less recent origin; but this will no doubt be put right in a second edition. Most of the detailed information given in the book is fully documented by numerous references to original papers and, wherever possible, the existence of recent reviews is also indicated. In addition, the introductory chapter of the book encourages the student to do his own exploration of biochemical literature by providing an excellent guide to the main journals, reviews and books (dates of publication and editions are omitted from the books) in which articles of biochemical interest are to be found.

In dealing with text-books of this scope, there are bound to be differences of opinion about what should be included. The inclusion of a good deal of physical chemistry at the beginning is fully justified, but it seems a pity that such a comprehensive book should not devote at least one chapter exclusively to plant biochemistry (there is a section on photosynthesis under carbohydrate metabolism), and another to the biochemistry of bacteria and fungi. No doubt limitations of space and the anthropocentric interests of medical readers dictate these omissions, but the type of reader to whom this text-book will prove most useful needs as broad an outlook as possible. There are also fewer figures and drawings than one might expect in a book of this size; this is particularly noticeable in the case of those illustrations which have been found perennially useful in the teaching of students, such as diagrams of the apparatus used in determinations of energy metabolism. A curious feature of the section of protein chemistry is the omission of any reference to paper partition chromatography, although six pages are devoted to other methods of separating amino-acids.

In general, however, this book represents a remarkable assimilation of biochemical knowledge on the part of the two authors, and they are to be congratulated on producing an advanced text-book of such quality without resorting to the technique of multiple authorship with its attendant loss of continuity.

H. N. MUNRO

A. W. CONWAY: SELECTED PAPERS

Selected Papers of Arthur William Conway

Edited by Prof. James McConnell. Pp. viii+222. (Dublin: Dublin Institute for Advanced Studies, 1953.) 21*s.* net.

IRELAND has been the birthplace of several great mathematical physicists—above all, Sir William Rowan Hamilton. For a long time they were mostly at Trinity College, Dublin; but towards the end of the nineteenth century the torch passed to University College, Dublin, the staff of which included A. W. Conway and J. A. McClelland. This selection of the most important of Conway's papers has been edited by Prof. J. McConnell and published by the Dublin Institute for Advanced Studies, which was founded on the advice of Conway by his former pupil, Mr. de Valera. It is preceded by the twelve-page obituary notice written for the Royal Society by Sir Edmund Whittaker, which contains a detailed analysis of Conway's researches.

The first paper reproduced and several later ones concern the classical electromagnetic equations and the point electron, which is regarded as a moving singularity of the differential equations. The use of contour integration to calculate the field is particularly striking. This work on moving electrons led on naturally to the study of the origin of spectra. Conway's paper of 1907 was the first to break away from the old idea that the spectra corresponded to the natural periods of oscillation of the atom, though it fell short of the much greater advance made by Bohr six years later. In 1913 Conway returned to the problem. He had not yet accepted the point of view of Bohr's paper, published a few months earlier, and tried to utilize J. J. Thomson's suggested model of the atom. However, in later years Conway finally accepted the Rutherford model of the atom, as used by Bohr, and published papers on these lines dealing with non-central forces and with some discrepancies between experiment and theory in the helium spectrum. He also treated the helium problem by Schrödinger's wave mechanics.

The heavy task of editing (in collaboration with Profs. J. L. Synge and A. J. McConnell) Hamilton's collected papers on optics and dynamics, many from previously unpublished manuscripts, led Conway to extend some of Hamilton's work. He showed that the Hamiltonian principal function can be obtained immediately from a complete integral of Hamilton's partial differential equation. The last four papers in this selection apply Hamilton's quaternions, for which Conway had long cherished a great admiration, to relativity and quantum mechanics. In particular, he used quaternions to replace matrices in the study of Dirac's relativistic wave equation. Thus his last paper, in 1948, may be considered as the natural development of his first work, the essay on quaternions written for a junior fellowship in 1900.

H. T. H. PIAGGIO

Thermionic Valves

Their Theory and Design. By A. H. W. Beck. Pp. xviii+570. (Cambridge: At the University Press, 1953.) 60*s*. net.

One of the dangers besetting the competent mind has been well put in the "Hippolytus" of Seneca: "He who is able to do too much wants to be able to do more . . .". This is the impression gained on reading this book. The author presents the theoretical basis of valve studies by dividing the subject-matter into three parts: (1) thermionic emission; (2) electrons in fields of charged conductors; and (3) valve properties, with a bias towards microwave tubes, including travelling-wave tubes and magnetrons.

There is admirable logic in this arrangement. Unfortunately, the author has not reached the high stage he has set himself, mainly through failure in adequate presentation at a uniform level. For example, in Part 1 the treatment of the Fröhlich–Wooldridge theory is not easy to follow; in Part 2, the chapters on 'electron optics' should be directed mainly to showing its relevance in valve design. In Part 3 the author shines best in dealing with the principles and theory of velocity modulation, bunching effects of space charge, klystrons, frequency pulling and noise; there is a good critical discussion on the usefulness of the Llewellyn theory, and also on the Brillouin steady-state conditions in magnetrons. Other topics dealt with include space-charge oscillations and the radio-frequency field in the interaction space; however, in many cases the diagrams require much fuller explanation. The final chapter on "Storage Tubes" seems out of place and could well have been omitted.

On the whole, readers will gain most from discussions on practical applications and limitations, in various parts of the text. These are generally good. One cannot help feeling that a more appropriate title would be "Source Book on Thermionic Devices", for the text requires to be supplemented by considerable outside reading for full advantage. The bibliography given is ample and helpful for this purpose. L. Jacob

Bakterien unter Hemmstoffwirkung

Elektronenmikroskopischer Bildatlas. Von Dozent Dr. G. Bringmann. Pp. 16+Tafel 1–101. (Berlin-Wilmersdorf: Transmare-Photo, G.m.b.H., 1954.) n.p.

This electron-microscopic study of the action of inhibitors on bacteria is presented as a collection of a hundred and one unbound electron micrographs with a fifteen-page descriptive booklet. The booklet briefly outlines factors to be considered in interpreting alterations of cellular appearance, techniques used in this study and the changes that cytological structures of bacteria undergo when acted upon by various antibiotics, chemical disinfectants and chemotherapeutic agents.

A large proportion of electron micrographs is devoted to the effects of penicillin on *Bacterium proteus* (*Proteus vulgaris*); some interesting micrographs of long filamentous cells and L-forms arising in the penicillin-containing cultures are included in this part. Unfortunately, most of the electron micrographs of bacteria treated with the various agents have been taken at the stages culminating in extensive autolysis and degeneration of the cells. Thus little can be seen of the more immediate effects of the drugs, etc., on the cellular organization. It is a pity, too, that there are no shadowed preparations, as these would have shown more clearly any changes in the surface structures.

However, this collection does show the gross cytological alterations that many organisms undergo on exposure to antibacterial substances, and as such it has some value for illustration purposes. The collection would have little appeal to the experienced research worker in this field. M. R. J. Salton

Nature, Mind and Modern Science

By Prof. Errol E. Harris. (The Muirhead Library of Philosophy.) Pp. xvi+456. (London: George Allen and Unwin, Ltd.; New York: The Macmillan Company, 1954.) 35*s*. net.

In this well-written and attractive book, Prof. Errol E. Harris asks his readers to reconsider the almost nihilistic position assumed by many present-day philosophers. He rejects firmly but courteously the positivism of Wittgenstein and of Carnap, and—for different reasons—the historical views of Collingwood. There are, for the author, certain basic philosophical problems which man can, in a finite sense, solve. The particular one most in question is the relation of mind to nature, and the inquirer is well conducted through the development of Greek thought and Renaissance *Methodik* to the general outlook demanded by contemporary physics.

What perhaps is the most intriguing remark in the whole volume occurs on p. 14, where suspended judgment in the face of uncertainty is postulated. This is indeed nothing but a very practical—and welcome—application of Husserl's 'reduction' or 'bracketing'. In almost the next sentence comes the confirmation that this supplies the place of the universal doubt of Descartes. There could be no clearer example than this of the *epoché* of phenomenology going into action.

Whether one agrees with Prof. Harris's main contention—namely, the existence of perennial philosophical problems—or not, this is assuredly a book to be recommended. F. I. G. Rawlins

The Observer's Book of British Birds' Eggs

Compiled by G. Evans. (The Observer's Pocket Series.) Pp. 217. (London: Frederick Warne and Co., Ltd., 1954.) 5*s*. net.

Another book has been added to the famous little Observer's Series. The eggs of 180 species are described with the utmost accuracy. Mr. H. D. Swain's 154 coloured illustrations are excellent and will be a considerable help in field identification. Each egg is drawn to its natural size and accompanied by a very useful text on the nest, nesting period and notes on the bird concerned. A foreword has been written by Philip Brown, secretary of the Royal Society for the Protection of Birds. He explains that a book about birds' nests and eggs might be dangerous, for it might encourage people to interfere with nests and generally do more harm than good. But he goes on to say that everyone interested in birds likes to find a nest and that a book of this kind should help them, so that the good it will do will undoubtedly outweigh the harm.

The eggs are classified in the Witherby order and not in the Wetmore order, which is now internationally accepted.

This book should be in every naturalist's pocket when on his field excursions. Bruce Coleman

THE HISTORY OF SCIENCE IN MODERN EDUCATION*

By Dr H. HAMSHAW THOMAS, M.B.E., F.R.S.

FORTY years ago, or more, students of the natural sciences formed a comparatively small part of the student population of universities of Britain; to-day a very different picture is presented. Men and women studying science, medicine, engineering, technology and agriculture are in the majority; students of the arts faculties form only about 43 per cent of the total number of undergraduates. This means that a very large number of people with the best potential intellectual capacity devote themselves each year to scientific or technological studies. Many of them should become leaders in thought and culture; they should play a leading part in society and in politics, and they will have to help in guiding Britain in the difficult times ahead.

A few years ago the University Grants Committee said in one of its reports, "A University would, in our view, fail of its essential purpose if it did not, by some means or other, contrive to combine its vocational functions with the provision of a broad humanistic culture and a suitably tough intellectual discipline". It seems to me to be a matter of considerable national importance that science students should be given that humanistic culture so that they may become effective and enlightened citizens in the days to come.

Many of those who are in close touch with students are becoming increasingly uneasy about the results of modern specialization, especially in science. Does the study of natural science in our universities include any real education which will help pupils to understand their fellow men? Does it train them to form sound judgments about the things of everyday life? Does it help them to live more happily in society?

Present-day science students have been specialists since the age of sixteen or earlier: they have a very limited knowledge of the world and of the behaviour of man, derived mainly from newspapers and the cinema screen: they know little real history, and are scarcely sensible of their debt to the past. Too often the student has a poor understanding of the meaning of words and of the implications which words can convey; hence he is unable to appreciate poetry and good prose. He is quite at home with formulæ and equations—the shorthand of science—but is seldom able to write fluent unabbreviated prose and to express his thoughts in a way that is easily intelligible to others. Even his ability to think logically and to understand the philosophical foundations of his own studies is often weak.

But we must not blame our students for these cultural deficiencies. They all must work extremely hard in endeavouring to learn and remember the vast body of information which is now presented to them, and which they are expected to understand and remember. Every branch of science has progressed enormously during the past fifty years, and the schoolboy of to-day is taught about subjects which, in my time as an undergraduate, were recent discoveries on the confines of knowledge. Moreover, while the field of study has been steadily increasing, very little of the older material has been omitted. Our universities seem to take little heed of the fact that the load placed on the science students is becoming, or has become, unbearable, and that this in its turn means a demand for more intensive study at school.

The training now given to students of the natural sciences is generally planned, consciously or unconsciously, with a view to the production of professional scientists who will spend their lives at research or teaching. But in fact a considerable number of people do not reach the necessary standard and have to look for other posts. Many men and women in this class have undoubted ability; they might become good administrators, works managers, journalists or business men, if their training were broader and less specialized. While the training of students is so detached from human affairs, they are seldom able or willing to embark on a career outside the limits of their own special subjects. For the same reason they are often unsuited to become really effective teachers in schools. The provision of some broad humanistic culture for the majority of university students is thus of importance both to the individual and to the community as a whole.

We must consider what can be done to remedy the situation which I have outlined. What modifications can be introduced into the teaching in the universities and schools to give the science students a broader intellectual training? One suggested remedy is the postponement of specialization until the pupils' minds are more mature, and the continuation of a study of a wide range of subjects up to or after entry into a university. I do not think this is a satisfactory solution of the problem. Some specialized study at school is valuable, even for those who will not go to a university; it can bring a wonderful zest into the intellectual life of many students. It is also necessary for those who look forward to a career in science, or in other subjects, to have the opportunity of showing that they have the capacity to begin advanced education with good prospects of ultimate success. But when a boy or girl has decided to embark on a particular course of study, all intellectual work which does not seem to be directly connected with the chosen field is regarded as a waste of time. The same consideration applies to students at the university, where the first-year undergraduate finds much new work to interest him and occupy his attention. The best method is not to impose a compulsory study of subsidiary cultural subjects but to widen our science teaching, so that it not only imparts information about the phenomena of Nature but also deals with the humanistic aspect of natural knowledge. If we can lead students to appreciate the way in which man's concepts of Nature have been built up, telling them of past failures as well as of successes, and revealing the personal characters of some of those who have worked in the search for knowledge, we should make them better scientists and at the same time illustrate the social and human aspects of their studies. All this can be done by the institution of well-planned courses in the history of science.

In speaking of the history of science I do not mean a mere knowledge of the names and dates associated with discoveries that have stood the test of time. In the first place, I should draw no hard and fast line between the history and the philosophy of science. Science is still in essentials 'natural philosophy', though the old name is now seldom used. The present-day search for the principles of things can scarcely be understood without reference to its history. Most young scientists need some philosophical training, and we have evidence at Cambridge that many of them find their introduction to philosophy most fascinating. This is an age when few specialists have had a philosophical training, and when non-specialists are unable to understand the language or details of many scientific subjects.

---

* From the presidential address to the British Society for the History of Science, delivered on May 3.

Some tentative suggestions may be made as to the kind of teaching which might lead to a broader humanistic outlook. First, we might hope that a general survey of the history of scientific effort would give the student some idea of his own position in the world by reference to the past. The story of the empirical quest for knowledge, extending far back before our era, should not be passed over lightly. The discovery of the methods of extracting metals, of curing hides, of making pottery and raising crops and stock, represent substantial scientific achievements by primitive peoples. Still more remarkable were the abilities shown by the ancient Egyptians in fashioning and using stone on a scale that has never since been equalled, as well as in the construction of buildings, in mechanical problems, in dyeing, weaving, wood and metal working.

A concise account of Greek thought and culture and of the civilization of the Hellenistic age seems essential. The world owes so much to the Greeks that one who is ignorant of the main facts about Greek civilization and thought can scarcely claim to be educated. Some teaching about the philosophers, scientists and medical men of classical times would provide a means of introducing students to the life and thought of the ancients, and of showing how mathematics, mechanics, astronomy, medicine and systematic scientific thought found their early expression.

The organization of society in Greece and Rome, which is so closely linked with early scientific progress, is a topic through which an outline of the political history of Europe can be approached. I do not suggest the study of more political history than is necessary as a background for the consideration of the progress of civilization and the movements of thought. Of course, at many points after the sixteenth century the history of science becomes much linked with political events, and can scarcely be understood without reference to them. But battles and treaties, the struggle of men for the domination of governments, and much of the detail usually taught in ordinary courses on history need little attention. The history of science is essentially the study of the growth of ideas. The successive views on the nature of things, both living and non-living, should be followed. The factors which led to the formulation of these views should be examined, and especially the relation between experiments or observations and the opinions current at the time when these were made.

Some historians of science pay little attention to the erroneous hypotheses widely held at certain periods. But for the more mature students the study of theories like that of phlogiston or of the imponderable fluids may, I think, be very instructive. I often wonder what I should have thought about phlogiston had I been living at the end of the eighteenth century.

Of the general educational value of history there can be no doubt. The modern biological study of organisms in Nature shows clearly how present-day populations owe their existence to events and changes in the past. Scientific thinking should make us more and more conscious of the fact that we cannot understand man, his societies and his social systems without reference to history. Most boys and girls are taught some English history at school; but it seldom includes enough social history or references to changes in thought and technical skill. Some knowledge of the past and of the ways in which men have acted under different situations is also, I think, of the greatest value to all of us to-day when we have to face the complex problems that arise in both public and private affairs.

This reflexion leads to a consideration of what is probably the greatest deficiency in the education of the young scientist. How much does he know of human beings, their motives and desires, their hopes and fears, their affections and hates? Students of the classics, of literature, history and law become well aware of the complex nature of human personality and of its wide variety; but the scientist often seems to think that all men in the world have minds that work like his own. He does not realize the power of the more primitive human instincts, of racial and social background, and of early training. He is thus surprised or disappointed when other people do not act in the way in which he thinks they should behave. Some people appear to regard men as they would substances or organisms in an experiment, where an alteration of environmental conditions is expected to produce a predictable response. Human beings, however, seldom react in that way.

We may not be able to give our students very much insight into human personality; but through the history of science we may, at least, make him aware of the different ways in which some people have thought and acted in the past. The story of the lives of well-known scientists provides a considerable fund of material from which the development of character and the influence of personality can be illustrated. I think that writers and teachers might well pay more attention to the selection of biographical details to bring out the character, good or bad, strong or weak, of the people they describe. We can find among our records plenty of interesting human stories, showing love and affection, jealousy and hate, perseverance in the face of adversity, triumph and tragedy.

An entirely different aspect of our problem concerns the training of the young scientist in the use of his native language. So much of his written work is done in the form of tables and diagrams, graphs and formulæ, and so little in the form of connected prose, that one hears constant complaints about the inability of the young graduate to express his thoughts in a way that is readily intelligible to others. It may be that similar criticism may be made of the abilities of some arts students; but to-day, more than ever, the scientist should be able to express himself in language that can be generally understood.

While I do not think that a gulf exists between the scientists and the non-scientific public in Britain to-day, as is said to exist in the United States of America, there is considerable risk that one may develop in the future. Although we have some first-rate scientific journalists and broadcasters, there is also a tendency, not without foundation, to regard the scientist as the 'back-room boy' who knows little of the world around him. This may become more pronounced if our young scientists are unable to tell about their work and ideas in a way that the ordinary man can understand. To remedy this, I can only suggest that our pupils should be encouraged to read more books in good connected prose, like those on history and philosophy, together with some selected works by scientists well known for their prose style, and that they should be encouraged to try to imitate that style.

There is also much to be said for the study of some complete book or paper of outstanding importance, with special reference to the way in which the subject is presented, the evidence is brought forward, and the conclusion reached.

Many school and university teachers will have a short reply to what I have been saying. They will point out that young scientists have already more than enough to learn, and that they have no time to spare for the kind of instruction I have suggested. This, without doubt, is perfectly true at the present time; but the day must soon come when every British university is forced by the accumulation of knowledge to revise its science-teaching and to make radical changes. Those responsible must face the problem of whether teaching or education is to be the first consideration. When this revision comes I hope that it will enable science students to devote some time throughout their education to the history and philosophy of science, so that they may obtain a good measure of humanistic culture, and will not tend to become cut off from the intellectual interests of their fellow students.

This brings me to another aspect of my subject, the value of the history of science to those who are not science specialists. In the past, a knowledge of the phenomena of Nature was considered quite unnecessary in the education of those who would not become medical men or science specialists. For a long time the part played by the scientific revolution of the seventeenth century in altering the currents of man's thought and in improving his material environment was clear to those who cared to think about it. But it received little attention, and the practical results which followed and which led to great improvements in our health, food, housing, transport and communications were taken as matters of course. To-day, most educated people have suddenly awakened to the fact that the discoveries of science have brought about the most profound change in human affairs that the world has yet seen, at least since the discovery of metals. No longer can young people be brought up in complete ignorance of modern science. But this does not mean that they can or should be taught chemistry and physics to enable them to understand the process of atomic disintegration, or learn physiology and genetics for the explanation of blood transfusion. What I think is needed is a general picture of how man's knowledge of Nature has come about, and what have been the results of this knowledge. In several schools a successful attempt is being made to inform pupils, by teaching the history of science, of the ways in which discoveries have affected men's lives. The historical approach enables the more important contributions to knowledge to be linked into a connected story. At the same time, it enables many inventions and principles to be understood by reference to the way in which they have developed from simple beginnings. Thus the early experiments of Faraday on electromagnetic induction are not difficult to understand, and when these are known the principle of the modern dynamo can be explained. By this mode of study much can be done to show the way in which biological and medical knowledge has altered the lives of the people of the world, and, may I add, to direct attention to the unacknowledged debt of the inhabitants of Asia and Africa to the labours of European and American scientists. This study will also stress the importance in our lives of vaccination and inoculation, the dangers of bacterial and virus infection, and the value of hygiene. In these days when so many people are terrified by reports of atomic weapons, there is in some minds a feeling that the progress of discovery in the world of Nature is to be regretted; scientists are only regarded as the authors of horrible contrivances. How important it is to show the manifold ways in which everyone has benefited from the labours of the investigators of Nature.

INTERNATIONAL PEAT SYMPOSIUM 1954

THE first International Peat Symposium was held in Dublin during July 12–17 under the auspices of Bord na Mona—the statutory corporation set up in Ireland to develop the peat resources of that country. It was attended by more than two hundred delegates from nineteen countries, and sixty-nine papers by delegates from thirteen countries were discussed. Nations as far apart as the United States and Malaya were represented; but one large peat producer—the U.S.S.R.—was absent. However, its near neighbour, Finland, was well represented, as were the Scandinavian countries and Austria.

The reason for this widespread interest in peat varies. In Ireland it is its immediate use as a fuel, followed by the reclamation of the bog for agriculture and afforestation. Elsewhere it may be the conservation of native fuel for use in an emergency, or even the employment of evacuees. Whatever the reason, there is no doubt that interest in peat is more intense now than formerly. In the past it was stimulated by war-time conditions, when other fuels were difficult to obtain, and tended to flag in peacetime. At the present time, economic conditions are such that in some regions peat can compete with other fuels on a calorific basis, particularly when modern methods of production and utilization are used. This has led to more research and development, which in their turn have resulted in further improvements in methods and still greater incentives to use peat.

The scope of the conference covered a wide field, including the initial survey and classification of resources, the winning and preparation of the raw material, its utilization in all types and sizes of equipment and, finally, land reclamation.

It was noteworthy that at every stage the discussion was dominated by the same characteristic properties of the material, particularly the large weight and volume of raw material required to produce a given quantity of dry peat substance, its variable composition, and, above all, its high moisture content. Their importance was made strikingly apparent during a visit by the delegates to typical peat bogs and power plants to observe various methods of winning and utilizing peat.

This left the general impression of a long-drawn-out struggle against natural conditions requiring a series of huge machines systematically to traverse many miles of desolate open country and to handle vast quantities of difficult material only to produce in the end a disproportionately small output of useful heat or power. Taking actual figures, it is hoped that by 1960 it will be possible to remove about 90 million tons of material each year from the Irish bogs to generate about one and a half million megawatt-hours of electricity. In comparison with this, Battersea Power Station generates slightly more power from about three-quarters of a million tons of coal per annum.

To estimate peat resources on a national scale is a formidable task in view of the large areas involved (one-third of Finland and one-seventh of Ireland consist of peat bogs), and the need to take into account variations in bog depth and in the quality of peat in different areas and at different depths. Nevertheless, several countries have made comprehensive surveys, the results of which were made available. One interesting suggestion which may reduce the cost and labour involved in future surveys was that surface vegetation can be correlated with the nature of the peat beneath it, and this will enable useful information to be obtained by relatively inexpensive aerial surveys.

Although peat has many uses, for example, as moss litter and for horticultural purposes, its main value is as a fuel, and it was mainly discussed as such. In passing, it is interesting to note that peat is still won by hand and used for household purposes by the same methods as were described by Pliny nineteen centuries ago. On a larger scale, its winning and utilization are extensively mechanized; but the conference made it abundantly clear that even now the methods employed have by no means reached finality. Thus the two power stations already burning peat in Ireland both use it in the form of machine-cut sods or turves; but Bord na Mona has now pinned its faith to granular peat won by a completely different method—the milled peat process—and it is its present intention to produce one million tons per annum of sod peat, about half of which will be used for domestic and industrial purposes and about half for power production, plus 2½ million tons of milled peat, most of which will be used for power production.

Since this decision was made, new machinery has been developed which will reduce very considerably the amount of labour required in the preparation of sod peat, and this must materially affect the relative economies of the two processes, although not necessarily to the extent of reversing their former order of merit.

Although mechanically very different, the fundamental difference between the two principal methods of winning peat is in the provision made for partially drying the fuel. An undrained peat bog usually contains about 93 per cent of moisture, that is, more than 13 lb. of water per pound of dry peat substance. Part of this moisture can be removed by drainage; but even then the remaining moisture, say 90 per cent, is far too much to be removed by waste heat, and the nature of the peat is such that it cannot be removed by ordinary mechanical means. Recourse is therefore made to air drying, and the basic difference between the two processes lies in the methods used to bring the fuel into contact with the air. In the sod peat process a strip about six feet wide and nine feet deep is cut from the previously drained bog and, after maceration, spread on the field to dry in the form of sods about 12 in. long and 4 in. wide It is then subjected to periodic turning and stacking and is eventually formed into a long pile in which it is stored until required for use. In the milled peat process, a thin layer about half an inch thick is removed in granular form from the top surface of the previously drained bog by means of a toothed roller and is repeatedly brought into contact with air by harrowing and similar means. Both processes depend upon weather conditions, and on the average during the summer months there will be two harvests of sod peat and fifteen to twenty-five of milled peat

The seasonal nature of peat winning and its dependence on day-to-day weather conditions, combined with the remoteness of peat bogs from towns and their amenities, involve many labour and sociological problems which, though not discussed in detail, were obviously in the minds of the delegates. Some of these problems would be at least partially solved if some continuous method of drying could be evolved which would be independent of weather conditions and yet economic.

Of the many methods which have been tried, osmosis has been found to be possible but not economic, and 'wet carbonizing' followed by pressing, though found wanting in the past, is still the subject of experiment. Another alternative is to use the Madruck process in which peat powder, previously dried down to about 12 per cent moisture, is mixed with wet peat and the mixture subjected to high sustained pressure; the suggestion being that the dried powder provides channels through which the water escapes while the peat is still under pressure. The moisture content of the final product is about 80 per cent, that is, more than half the moisture is removed in the press. Experimental work with the Madruck process using specially designed presses is now being carried out in Britain by the Ministry of Fuel and Power. If this is successful and enables peat winning to proceed continuously throughout the year, it should greatly ease the future economic position with regard to both capital costs and labour.

In the past, when peat was considered only as an alternative to other fuels, it was almost invariably burned in appliances designed primarily for those other fuels and modified as little as possible to burn peat. There is now a greater tendency to develop special apparatus which takes advantage of the favourable properties of peat, such as its high reactivity, and minimizes the effect of adverse properties such as high moisture content and low bulk density. Modern apparatus also takes account of the high volatile content of peat and the high percentage of carbon dioxide in its distillation products.

The two Irish power stations burning sod peat use more or less conventional chain grates with special pre-drying of the fuel by means of hot air; but the equipment to burn milled peat in the new stations will require further development work. Powdered peat has already been used for large-scale power production in the U.S.S.R.; but apart from this, experience is not available, unless it be assumed that peat can be burned efficiently by methods similar to those already used extensively on the Continent to burn brown coal. With this in mind, three German manufacturers were commissioned to design and construct three different boilers which will be used for gaining experience of burning milled peat in the new Ferbane power station. In these boilers either finely divided fuel will be burned in suspension after being dried by hot gases while passing through a Krämer mill of the type used for brown coal, or, alternatively, the spreader-stoker system will be employed in which the original milled fuel is projected into the boiler furnace in such a manner that the finer particles are burned in suspension and the coarser particles fall on to a form of chain grate where their combustion is completed.

The combustion of peat in small-scale equipment is equally the subject of experiment. Taking domestic heating as an extreme case, more economical methods of burning peat in the open fireplace have been devised; but Bord na Mona recommends the use of closed stoves of special design, and ultimately completely automatic mechanical operation. At the other extreme, large heating boilers are said to give good results when fitted with a furnace of Dutch design which consists essentially of a low-velocity cross-draught gas producer delivering gas into a combustion chamber, where it is burned with carefully controlled secondary air. The most promising device, however, would appear to be a modification of the downjet burner to burn broken sod peat in both domestic and small-scale industrial appliances. Its essential feature is that all the air for combustion is directed as a high-velocity jet upon the top surface of the fuel bed and it can be used over an exceptionally wide range of loads, giving a very high output per unit volume and per unit grate area, and complete combustion with very little excess air.

The high moisture content of peat makes its possible use as a gas turbine fuel of special interest, first because the gas supplied to the turbine is necessarily at a low temperature in order to avoid overheating the blades, and secondly a large quantity of exhaust gas is available at a temperature which permits it to be used for drying. In experiments with the open-cycle gas turbine carried out under the ægis of the Ministry of Fuel and Power, the problem of feeding pulverized peat under pressure has been solved by the use of a fluid-bed feed in conjunction with a 'coal pump', and combustion does not appear to be too difficult. Problems of blade abrasion, corrosion and ash deposition in the turbine are, however, still unsolved, though under active investigation. In the closed-cycle gas turbine these particular difficulties are avoided by using indirect heating and a clean working fluid, but the system involves more elaborate heat exchangers, including a large 'air boiler'. A contract has been given for a 2,000-kW. peat-fired closed-cycle set to generate power in the north of Scotland and an experimental 750-kW. open-cycle set will be erected on the same site.

Apart from its present uses, more or less in its raw state, serious consideration has been given to peat as a potential source of high-grade manufactured products. It has, for example, been found possible to extract from it a wax which may itself be converted into new plastics. Attention has also been given to the gasification of peat to make either water gas or synthesis gas, and Bord na Mona has examined a number of complete gasification processes as possible starting points for the manufacture of synthetic ammonia for conversion to fertilizers.

Whatever the method by which peat is utilized, the final stage of exploiting peat resources must be the reclamation of the land, and most of the last two sessions of the Conference were devoted to this subject. In them it was evident that the best use which can be made of the land, whether for grassland, arable land, or forestry, is a complex question, the answer to which depends upon many factors, such as drainage, acidity and existing vegetation. Much information is now available on this subject, but active research into its many aspects still continues.

T. F. Hurley

OBITUARIES

Prof. T. F. Dreyer

Thomas Frederick Dreyer passed away suddenly on July 13, while discussing problems concerning Florisbad with his colleagues. For the past few years, in spite of severe set-backs to his failing health, his main interest was in trying to elucidate the many puzzling features which had been uncovered at the now world-famous site where in 1932 he had discovered the remarkable Florisbad human skull. The amazing wealth of archæological and palæontological material from this site had been increased by the 1952 expedition of the National Museum, Bloemfontein, and Prof. Dreyer was working against time in order to give his findings to the scientific world. Unfortunately, his death prevented him completing this research work.

Dreyer was born in the Cape Province on May 7, 1885, took his M.A. degree in the University of the Cape of Good Hope and the degree of D.Phil. *cum maxima lauda* at the University of Halle. After periods of study at Naples and in the United States and Australia, he served for a few years as entomological officer in the South African Agricultural Department. In 1912, at the youthful age of twenty-seven, he became professor of zoology, and in addition for a short period professor of geology, at the Grey University College (later the University of the Orange Free State), a post which he filled with distinction up to his retirement in 1950. He had also been responsible for courses in archæology and bacteriology. He continued his research work at the National Museum, Bloemfontein, up to the time of his death.

In addition to his brilliant career as professor of zoology in the University of the Orange Free State, he devoted much of his spare time—and money—to investigating, uncovering and describing some remarkable sites, three of which are of extreme scientific importance, namely, the Matjes River Shelter, the Kakamas area of prehistoric Hottentot graves, and Florisbad. These sites have contributed much, archæologically, anthropologically, and palæontologically, towards clearing up the prehistory of South Africa. There are very few regions in South Africa which Prof. Dreyer did not investigate, and his remarkable and rich collection was presented to the National Museum, Bloemfontein, where it is now housed in the T. F. Dreyer Hall for Anthropology and Archæology.

Those who passed through his hands as students or were fortunate enough to be associated with him in his research work bear only the kindest memories of a big soul. A great worker with boundless energy, he infected his associates with his enthusiasm and gave loyalty for loyalty. A doughty fighter, he could hit out hard during constructive arguments; but never allowed varying points of view to cloud his personal contacts.

His interests extended beyond just his work and research. This is amply demonstrated in the variety of positions held during his career, including member of the Bloemfontein Town Council, chairman of the Governing Council of the National Museum, chairman of the Senate of the Grey University College, of the Senate of the University College of the Orange Free State, and chairman of the Senate of the University of South Africa. His interests extended to locust control, and he was also asked by the Provincial Authorities of the State, to direct the investigation of freshwater fisheries in this province.

As time goes on, the important contributions Prof. Dreyer has made to the archæological story of South Africa and to the study of prehistoric man in this region will be more clearly seen in their true perspective and recognized for their importance. His collections have been on too great a scale for his personal complete description and publication, and will still be an important source for future research. Without them no true picture of South African prehistory is possible.

We, who were privileged to be closely associated with Prof. Dreyer, know how severely he suffered during the past two years and daily were witness to mind triumphing over body. In spite of the physical drawback, his clear memory, fast-working brain and keen interest never flagged for a moment nor deserted him. He thoroughly deserved that much-desired end —to die in harness. A. J. D. Meiring

---

The passing of Prof. T. F. Dreyer has deprived the study of early man in South Africa of one of its acknowledged leaders, and his place will not be easily filled.

Outside South Africa, Prof. Dreyer will be most widely remembered as the discoverer of the Florisbad skull, the most remarkable human fossil to be found in Africa since the Broken Hill skull. This discovery was a well-deserved reward for his intuition in selecting for thorough investigation the Florisbad mineral spring deposits with their wealth of archæological and fossil mammalian remains. But his explorations in the Matjes River Cave and elsewhere also constitute notable contributions to our knowledge of man in South Africa from prehistoric to historic times.

With a characteristic scorn for the compartmenting of knowledge, Prof. Dreyer pursued his studies simultaneously in the field of physical anthropology, Quaternary mammalian palæontology, archæology and even Quaternary geology and climatology. Such a broad approach, allied to the natural vigour and freshness of his mind, gave birth to original and challenging interpretations of his discoveries. However these may fare in the light of future increases in our knowledge, there can be no doubt that to the present generation of investigators in South Africa they have been a most valuable stimulus.

Prof. Dreyer was not only distinguished in the field of research; he was also an inspiring teacher. Moreover, as a senior professor his wide-ranging and lively intelligence did valuable service both within his own University and over the whole field of university and professional education in South Africa.

The vigour with which Prof. Dreyer maintained his opinions might lead a casual reader of his writings to misconceive him as an acrimonious controversialist. To encounter him personally was to find him quite otherwise: courteous, kindly and charming. As human being as well as scholar, he will be remembered with honour and with affection.

L. H. Wells

Prof. H. G. A. Hickling, F.R.S.

Henry George Albert Hickling, emeritus professor of geology in King's College, Newcastle upon Tyne, died on July 26 in his seventy-second year. He was born on April 5, 1883, in Nottingham. His school education in that town was followed by three years private study in Scotland, where the rugged cliffs of Angus were to inspire him with the love of geology. He learned the fundamentals of this science from Prof. W. Boyd Dawkins in the University of Manchester. He graduated in 1905, and after two years further study and research he became in turn lecturer in palæontology and geology in 1907 and reader in geology in 1917 in Manchester. Owing to the absence in India of Prof. T. H. (later Sir Thomas) Holland during the First World War, Hickling was acting head of the Department. In 1920 he became professor of geology in Armstrong College (now King's College), University of Durham, Newcastle upon Tyne, a post which he held until his retirement in 1948.

In 1934 he received the Murchison Medal from the Geological Society of London and in 1936 he was elected a Fellow of the Royal Society. In 1935 he presided over Section C (Geology) of the British Association. He also served on the Council of the Geological Society, on the Geological Survey Board and on the Fuel Research Board.

His research was mainly in the fields of palæobotany, coal-measures tectonics and coal petrology. During his Manchester period he published papers on palæontology, and on the stratigraphy of the Old Red Sandstone of Angus, and a paper on the nature and origin of the Cornish china-clay, in which he advanced a new and original theory of its genesis. During the same period he made a detailed study of the tectonic structure of the Lancashire coalfield, a work published in 1924 as a coloured map of the underground contours of a single coal seam—the Trencherbone seam—supplemented in 1927 by a book, "Sections of Strata". At a later date he applied the same method of mapping to the coal seams of the Northumberland and Durham coalfield (1950).

Hickling's most striking contribution to science, and the work for which he was best known, was in the field of the study of coal. Following on the pioneering work in Great Britain of James Lomax on the micro-petrology of coal, Hickling's first paper on this subject (*Trans. Inst. Min. Eng.*, 1917), followed by a paper on the chemical relations of the principal varieties of coal (*ibid.*, 1927), opened up a series of publications by him and by his pupils on the microstructure and on the chemistry of coal—a new and very important contribution to coal science, and one which received world-wide recognition.

Hickling was very keen on local geology, and he was responsible for the preparation of accounts of the geology of Northumberland and Durham for the meeting of the Geologists' Association in 1931 and for the meeting of the British Association in 1949. His interest in geology as a subject of popular education was already shown in his younger days when he published his book "Geology: Chapters of Earth History", and right through his academic career he was very much appreciated as a popular lecturer. He was also interested in water supplies, a subject on which he was an acknowledged authority.

This stark enumeration of facts will not convey to the generations of students, who revered and loved him, the Prof. Hickling they knew in the lecture room, laboratory and field and whose home was always open to them. His clear logical exposition and the slow tempo of his speech, whether in lecture or conversation, made misunderstanding impossible, and will be as well remembered as his rapid pace as a leader of field expeditions and his speed when driving. Despite his undoubtedly important original contributions to science, it will probably be as a teacher that most people will think of him. His teaching career, covering some forty years, belonged in the main to a period when mechanical aids were few and buildings and general equipment inadequate. In such circumstances the personality of the teacher was all in all and Prof. Hickling's innumerable past students, many of them now famous themselves, will bear witness to his pre-eminence in this respect.

His first wife (Gertrude Hermine Geiler), whom he married in 1910 and who died in 1952, was herself a medical doctor of distinction and a pioneer in the nursery-school movement, and she co-operated loyally with him. Together they built up a tradition of friendliness, with which, as with that of disinterested scholarship, the name of Hickling will always be associated. S. I. TOMKEIEFF

Dr. W. C. F. Shepherd

WILFRED CHARLES FURNESS SHEPHERD, deputy director of the Safety in Mines Research Establishment, Sheffield, died suddenly at his home on July 19, in his fifty-second year. He had just returned from Germany after attending an International Conference of Directors of Safety in Mines Research at Dortmund.

From Manchester Grammar School, in 1919, Shepherd joined the staff of the late Prof. R. V. Wheeler at the Home Office Experimental Station, Eskmeals, Cumberland, in research on means of minimizing risks of ignition or propagation of explosions of firedamp or coal dust in mines, and devoted the whole of his working life to this purpose. He became well known in all the mining countries of the world for his research on explosives; the much greater safety of mining explosives in use in coal mining to-day in comparison with thirty years ago is an achievement of research teams of which Shepherd became a leading figure.

In his early years he was occupied with the ignition of methane by hot wires and the photographic study of movement of flame in gaseous mixtures in tubes, work related to the safety of electric and flame safety-lamps; but he soon joined the section, directed by the late W. Payman, engaged in investigations of the ignition of firedamp by mining explosives. Payman was applying schlieren photography to the study of the part played by pressure and shock waves in the ignition process and, in 1929, Shepherd was asked, under an arrangement for the exchange of staff, to work in the laboratories of the United States Bureau of Mines. Here he made his first friends among overseas research workers, with whom he maintained an active correspondence for the rest of his life. His year and a half's study of the ignition of firedamp by explosives, by the schlieren method, was published in a Bureau Bulletin in 1932. On his return, he continued work on this subject; many of his findings were of fundamental interest. He published two papers in the *Proceedings of the Royal Society*. A notable contribution was the demonstration of quasi-detonation in methane–air mixtures under the influence of projected hot particles. He studied the ignition of gaseous mixtures by impulsive pressures produced by the bursting of diaphragms in shock tubes. He showed that surprisingly low pressures were sufficient to ignite mixtures of certain inflammable gases and oxygen and that ignition could even ensue from rapid expansion, that is when, for example, a methane–oxygen mixture under pressure in a tube was released into open air by the bursting of a restraining diaphragm at one end. This novel expansion–ignition phenomenon was the subject of a paper written shortly before his death. It was during this pre-war period that, with D. W. Woodhead, also in Payman's group, he developed the instrument which became known as the Buxton rotating-mirror camera.

During the war years Payman and his colleagues turned to work, under the Ministry of Supply, with military explosives, on problems relating to the detonation of shaped charges and the fragmentation of projectiles. The years 1940–45 were a period of intense activity and provided valuable experience in the development and application of new techniques. Shepherd's inventive and organizing ability assisted the team in making important contributions to armament design. Most of the work necessarily remains unpublished. The work for the Ministry of Supply continued after the War, and at Payman's death in 1946 Shepherd took over the direction of the team, and, at the same time, guided the re-establishment of the team devoted to research on coal-mining explosives. He initiated a long-term research programme and, as a more immediate practical contribution, in close collaboration with the explosives industry, he fostered the development of 'equivalent to sheathed' mining explosives in place of the sheathed explosives which were falling short of the hoped-for standard of safety. He published with H. C. Grimshaw a number of papers on these new explosives that, before his death, were meeting a third of the United Kingdom requirements.

From 1947 the responsibility for mine safety research was assumed by the Ministry of Fuel and Power, and the research of the Safety in Mines Research Establishment was expanded. Shepherd was promoted first senior principal scientific officer and then deputy chief scientific officer and became deputy director of the Establishment. He retained his interest in explosives research, and in recent years assisted in initiating research on quite new methods of blasting, convinced that the problems of mining would not be solved by research directed solely to the study of the explosives. Prompted by the disastrous fire at Creswell Colliery, he directed the formation of a new team for fire research to work on mining problems in collaboration with the Joint Fire Research Organization of the Department of Scientific and Industrial Research, and he published two authoritative papers on fire prevention. At the time of his death he was engaged in planning an important new programme of research on flame propagation and explosion prevention for the Factory Department of the Ministry of Labour and the Department of Scientific and Industrial Research.

His sudden death at the height of his powers is a serious loss to British mining research. Shepherd, though always modest and unassuming, was a man of much strength of character, who never spared himself throughout his working life. Many men in the world of mining both in the United Kingdom and in laboratories abroad will mourn his death. He leaves a widow and one daughter. H. C. GRIMSHAW

NEWS and VIEWS

New President of the British Association: Sir Robert Robinson, O.M., F.R.S.

General satisfaction will be felt at the announcement that Sir Robert Robinson is to be next year's president of the British Association for the Advancement of Science. Since 1930 Sir Robert has been Waynflete professor of organic chemistry in the University of Oxford, having previously served as professor of either chemistry or organic chemistry in the Universities of Sydney, St. Andrews, Manchester and London. He was awarded the Order of Merit in 1949 and holds the Longstaff Medal of the Chemical Society, and the Davy, Royal, and Copley Medals of the Royal Society, besides many foreign honours. He has already had a very notable experience of presiding over learned bodies, having been for two years president of the Chemical Society and for five years president of the Royal Society. Sir Robert's extensive scientific work lies in the field of organic chemistry. His investigation of the constitution, by degradation and by synthesis, of the anthocyanin group of plant pigments is already classical, as is that on the constitution of several groups of alkaloids. He has made notable contributions to the synthesis of steroids. He was one of the first to apply the electronic theory of valency to problems of organic chemical reactions, and has offered an attractive picture of the biogenetic relations of naturally occurring plant substances.

Research on Humane Vivisection: Dr. W. M. S. Russell

UFAW (The Universities Federation for Animal Welfare), in association with the Animal Welfare Institute of New York, has appointed Dr. W. M. S. Russell as research fellow to study the history and progress of the introduction of humane techniques into experimentation on animals, with the view of assisting further progress. Examples of progress already achieved are the use of anæsthetics in experiments involving operations, the reduction in the requisite number of animals by means of modern small-sample statistical theory, and in the assay of drugs the substitution of painless (for example, chemical) criteria for various criteria entailing discomfort. Dr. Russell, who will have the assistance of a consultative committee, has had a brilliant career at Oxford and is the son of Dr. F. S. Russell, director of the Marine Biological Laboratory at Plymouth. At present he holds a fellowship from the Agricultural Research Council. As an undergraduate he abandoned a Greek scholarship in order to study zoology, and he has written a number of papers on the behaviour of vertebrates, together with a forthcoming book on comparative physiology.

British Standards Institution, Chemical Divisional Council: Dr. G. H. Beeby

Dr. G. H. Beeby has been appointed chairman of the Chemical Divisional Council of the British Standards Institution and has, therefore, at the same time become a member of the General Council and the Executive Committee. Dr. Beeby, who is the well-known chairman of Imperial Chemical Industries Salt Division at Winsford in Cheshire, has spent all his working life in that organization. Born in Leicestershire, and educated at Loughborough College and the University of London, he joined the Billingham Division of I.C.I. as a chemist in 1928. Afterwards he spent thirteen years in I.C.I. sales offices before taking up his present duties in 1952. He first joined the Heavy Chemicals Industry Committee of the British Standards Institution in 1945, and has been its chairman, as well as chairman of the Institution's Sub-Committee for International Work on Chemistry, since 1948.

John Gould, F.R.S. (1804–81)

John Gould, who has an honoured place in the ranks of ornithology, was born at Lyme Regis in Dorsetshire a hundred and fifty years ago on September 14, 1804. At the age of fourteen he began working under his father, who had been appointed foreman gardener at Windsor Castle, and acquired an intimate knowledge of birds in their wild state and considerable skill in the art of taxidermy. In 1827 he became taxidermist to the newly founded Zoological Society of London. His first attempt at authorship was his description of bird skins received in 1830 from the Himalayas, "A Century of Birds from the Himalayan Mountains" (1832), and his own sketches, artistically transferred to stone by his wife, made this the most accurately illustrated book on foreign ornithology up to that time. A two-year expedition to Australasia (1838–40) was responsible for "The Birds of Australia", which took seven years to complete. He was elected to the Royal Society in 1843. Gould published forty-one folios on birds, illustrated with 2,999 plates, his best-known works being "A Monograph of the Trochilidae, or Family of Humming-Birds" (this collection was exhibited at the Great Exhibition of 1851), "The Birds of Europe", "The Birds of Asia" and "The Birds of Great Britain". Gould also contributed some three hundred memoirs and papers to the *Proceedings of the Zoological Society* and to other scientific journals. He died on February 3, 1881, aged seventy-seven, at Charlotte Street, near the British Museum.

Calendar Reform and the Seven-day Week

A pamphlet entitled "Calendar Reform and the Seven-Day Week: a Clarification", by Elizabeth Achelis, James Avery Joyce and Daniel Sher, is No. 5 of the World Calendar Pamphlets series, and is published by the Calendar Reform Association (pp. 30; 1954; 1*s*.). It is unfortunate that there is opposition to calendar reform from a few religious sects—Christian and non-Christian—the foremost critics being the Jews, chiefly because the Sabbath is fixed for the seventh day of the week and the proposed alterations would disturb this. The main disturbing factor is the use of a 'Worldsday' which, in the suggested scheme, is the 365th day, now dated December 31, and which would be a world holiday, dedicated to the brotherhood of man and a non-working day. Every year would thus begin on a Sunday, January 1. The objections are fully and fairly dealt with by Mr. Joyce, a British Methodist; and Mr. Sher, an Israeli Jew, shows the error of the points raised by the late Chief Rabbi Hertz on the spiritual and human rights of the minority, which were largely responsible for the somewhat hasty and erroneous action taken by Jewish organizations. A few examples show the faulty conceptions of such terms as 'day' and 'week'. Thus a person crossing the International Date Line may experience two successive Sabbaths or may miss one, passing directly from Friday to Sunday. Again, according to Jewish Law, the Sabbath lasts from sunset until sunset on the following day, but how could such a regulation be observed in polar regions where the sun neither rises nor sets for months ? These and other arguments show conclusively that the Sabbath is not absolute, but a function of physical and political geography. In addition, there are many precedents in Jewish history for the concept of the year undergoing changes, as, for example, making the month of Tishri the first month of the calendar year instead of Nisan, in flagrant defiance of the command mentioned in Exodus xii, 2. Except for a small body of Christian Sabbatarians, Judaism seems to be the only opponent of the reformed calendar on religious grounds, and if world opinion should show a substantial majority in favour of reform, it would be unreasonable to postpone the change in deference to the wishes of a race that represents only about 0·5 per cent of the world's population.

Directory of International Scientific Organizations

In accordance with a decision of the General Conference of the United Nations Educational, Scientific and Cultural Organization in November–December 1952, the second edition of the Organization's "Directory of International Scientific Organizations" (pp. 312. Paris: Unesco; London: H.M.S.O., 1953. 2.50 dollars, 13*s.* 6*d.* or 650 francs) has been published only in English, the language which commanded the larger sales of the first edition. It is arranged on similar lines to the first edition, and although certain bodies included in the first edition are now omitted in the absence of up-to-date information and other defunct ones are no longer listed, 264 organizations, as against 202 in the first edition, are described, though a few of those given in the "Miscellaneous" section appear to have somewhat slender claims to be regarded as scientific organizations in the usual sense of the term. As previously noted, the contents pages, with their interpretation of the initials and symbols so commonly inflicted on the reader in place of names and titles, and the adequate subject index make the volume a most useful reference work to men of science generally as well as to the librarian.

New Education Scheme of the Institute of Fuel

In the July issue of the *Journal of the Institute of Fuel* is an informative account of the new education scheme of the Institute of Fuel, contributed by the chairman of the Institute's Education Committee, Dr. D. T. A. Townend. Among the activities of such a professional body, the development of its educational aims must always be a matter of prime importance; for to a chartered body the professional competence and corresponding status of its members must be factors in which the highest standards must progressively be assured. One needs to recall the background against which the first education scheme was framed following the report of the Sibly Committee made more than a decade ago. That Committee, set up by the Advisory Council of the Department of Scientific and Industrial Research to inquire into the supply of trained fuel technologists, reviewed both the urgent short-term and the long-term problems involved; the educational activities of the Institute had in some measure contributed towards the progress envisaged. Some weaknesses in the early scheme were revealed by practical experience of its working, and these have been remedied in the new scheme now coming into operation. A professional body must always gather much of its strength from members educated in the universities and technological institutions. There are, however, in these days of part-time release from industry for further education, a large number of potential technologists, much needed in industry. The new scheme is particularly directed towards their welfare if their livelihood is concerned with the many-sided aspects of fuel technology. A grouped course of study is prescribed in which five years is intended to be occupied on part-time study of the scientific background and the technological essentials. For those who are fortunate enough to be able to profit by full-time educational facilities, a valuable detailed account is given of the resources of Britain in a collective statement which has not previously been made available to the intending student. The discussion of the scheme by the members of the Institute is appended to the paper.

Brotherton Library and Collection of the University of Leeds

The annual report of the Librarian, University of Leeds, for the session 1952–53 (pp. 12; from the University), records holdings of 365,912 volumes and 159,090 pamphlets at June 30, 1953, of which 266,053 volumes and 109,171 pamphlets are in the Brotherton Library. Special reference is made to the use of aluminium and plastic in the new mezzanine floor of the Brotherton Library in which radiating lines of bookcases converge on the centre of a circle 104 ft. in diameter, and the new floor and shelving are supported at basement-level by aluminium stanchions spaced at a uniform distance of 3 ft. 6 in. Horizontal supporting members are fixed at the top of the stanchions, which in turn support parallel beams, between which are inserted standard 'Holoplast' sheets. Each stanchion accommodates four perforated steel channels, the centres of the perforations being 1¼ in. apart, and this is the only use of steel in an otherwise entirely aluminium structure which is believed to mark a new departure in library planning. The new floor is covered with a cork linoleum specially treated to preserve its sound-absorbent quality.

The eighteenth annual report of the Brotherton Collection Committee of the University (pp. 10; University of Leeds, 1954) covers the session 1952–53, during which three main exhibitions were arranged. The first of these related to the Poets Laureate of England, the second to three Queens of England—Elizabeth I, Anne and Victoria—and the third was an exhibition of items from the collection of atlases, maps and road-books presented to the University by the late Dr. Harold Whitaker. The Collection was also open, usually with special exhibitions, to learned societies which were guests of the University; these included the Thirteenth British Congress of Gynæcologists and Obstetricians (July 1952), the Royal Astronomical Society (July 1952) and the British Association of Urological Surgeons (June 1953). Dr. E. E. Willoughby gave a series of four lectures on "The Uses of Bibliography to the Student of Literature and History" in the Brotherton Room during November. The contents of the Collection on June 30, 1953, were estimated at 24,220 books; 16,287 pamphlets; 608 manuscripts; 4,106 deeds; 32,269 letters; and 25 maps.

Fitzwilliam Museum, Cambridge: Report for 1953

The restrictions on new museum buildings are so severe in Great Britain at the present time that it is pleasing to note in the annual report for 1953 of the

Fitzwilliam Museum, Cambridge, that a building licence was granted for the Graham Robertson Room. This extension will provide a much-needed exhibition gallery and students' room, with storage accommodation, for water-colours and drawings. The work is due to be completed by October 1954. The Friends of the Museum have again been generous in their support, and purchases to the extent of more than £1,200 were made during the year. These included a porcelain dish of the Ming dynasty (Yung Period) decorated in blue, and a porcelain stem-cup decorated in red and green enamels and dated sixteenth century (Ming Dynasty).

Records of the Dominion Museum, Wellington, New Zealand

The "Records" of the Dominion Museum, Wellington, New Zealand (Vol. 2, Part 1; 1953), includes papers on ichthyological notes, with special reference to sexual dimorphism in some New Zealand fishes; the ecology of the vegetation of sand dunes at Piha; and a molluscan fauna from the Chatham Rise. Part 2 of the same volume consists of papers on Acantocephoba from Auckland and Campbell Islands, parasitic nematodes and trematodes from Campbell and Auckland Islands. Vol. 1 of this "Record" was published in 1942–44. Since that date, various publications have been issued; but it is now stated that, commencing with the present parts, the series of "Records" will continue.

Cross-Sections of Paints

An important article in the July issue of the *Museums Journal* by Joyce Plesters, of the National Gallery, London, details some experimental work on the preparation and study of layers of paint on pictures. For a proper microscopical study of the layer structure the paint fragment must be mounted and its surface prepared by sectioning. The embedding medium used is 'Maroo Resin S.B. 26 C', and full details of the process are given in the paper. The information about the physical structure of paintings that can be gleaned from a study of paint cross-sections is varied and a few specific and illustrated examples are recorded. Such matters as overpainting are quickly detected, and a clear distinction can be drawn between the original and subsequent additions. Facts of art-historical interest sometimes emerge from a study of paint cross-sections, and information regarding the technical methods used by the artists can generally be deduced. A collection of paint cross-sections is being made and with the corresponding chemical analyses form an interesting record of artists' techniques and palettes, and may indeed prove of definite diagnostic value in providing additional evidence for attributions.

Heat Transfer by Radiation

The Department of Scientific and Industrial Research and Fire Offices' Committee has produced Fire Research Special Report No. 2, "Heat Transfer by Radiation", by J. H. McGuire (pp. 29. London: H.M.S.O., 1953; 1*s.* 6*d.*), which deals with the configuration factor, and heat transfer between extended surfaces and between reflecting surfaces. The configuration factor, or geometrical factor, takes account of the geometrical relationship between a radiator of uniform temperature and emissivity, and a receiving element, and may be defined as the ratio of the intensity of radiation at the receiving element to the intensity near to the radiator. In the pamphlet the configuration factor integral, the additive property of configuration factors and the configuration cosine law are first derived, and then the geometrical and optical methods of determination of the configuration factor are briefly described. The various mathematical expressions for the configuration factors of the simple well-known surfaces—for example, plane, sphere, circular disk, cylinder, etc.—are listed and the use of the configuration factor tables relating to the various expressions is illustrated by the worked solution of a particular problem concerning a cylindrical flue pipe. The remainder of the report is devoted to radiative heat transfer when multiple reflexions can take place. Expressions are derived relating to infinite plane surfaces, two finite non-concave surfaces, concentric spheres and concentric cylindrical surfaces. The report is a useful collection of available information expressed in a form which facilitates numerical calculation, and with the increasing use of radiative heat transfer in industry and with the application of its geometrical principles to the illumination of buildings it should prove valuable to engineers working in these fields.

Solar Furnaces for High-Temperature Research

A brief but interesting account of recent progress in the design of solar furnaces for high-temperature research and development work, written by one who is actively engaged in this field of investigation, is given by W. M. Conn in the January number of the *Journal of the Franklin Institute* (257, 1; 1954). The principal advantages and disadvantages of solar furnaces in comparison with other means of obtaining high temperatures are discussed, and the various fields of study in which solar furnaces have been utilized or are expected to be of particular value are briefly outlined. A useful table is included in which data are given concerning recently erected solar furnaces at Jena, Germany, by the Zeiss Company; at Meudon and Mont Louis, France, by F. Trombe and co-workers; and at Kansas City, United States, by Mr. Conn and co-workers. The first large solar furnace units were used for qualitative work only; but recently solar furnaces for quantitative work have been developed, and various accessory equipment for heating and cooling a specimen according to a predetermined schedule, for maintaining it at a desired temperature and for air quenching is described. The development of solar furnaces for semi-industrial use is also discussed, and in one type mentioned the usual one-piece mirror is replaced by a collector consisting of a large number of small curved mirrors.

Work Study

The Association of British Chemical Manufacturers organized a two-day conference on works study at Buxton during October 9–10 for senior executives engaged in the chemical industry. The conference was arranged in order to implement one of the recommendations of the Heavy Chemicals Productivity Team, which visited the United States in the spring of 1952. The proceedings of the conference have now been brought together and cover all the addresses given, together with a summary of the main points which emerged at the meetings of the thirteen discussion groups. Among the addresses were descriptions of the techniques of method study and work measurement, the application of work study to financial incentive schemes, the effect of work study on labour relations and the introduction of work study into a factory. All these were contributed by members of the staff of Imperial Chemical Industries, Ltd., an organization which has probably had greater experience in the use of work study than any other in Great Britain. The whole volume has been well put together and will be of practical value not only to those who are introducing work study techniques into factories and offices but also to those who wish to familiarize themselves with its methods and jargon. Copies of the proceedings can be obtained from the Association of British Chemical Manufacturers, Cecil Chambers, 86 Strand, London, W.C.2.

Occupational Medicine in Finland

The Finnish Institute of Occupational Health has recently published its annual report for 1953, which shows how its work is rapidly expanding. In the past two years its staff has increased from 84 to 121 and now comprises the following departments: general, medical, physiological, psychological and industrial hygiene. In the physiological department particularly, a good deal of work has been carried out—some of it with the aid of money from State-controlled football pools—on such topics as the mineral composition of thermal sweat, age and athletic performance in ball games, ski-ing and in wood-cutting, factor analysis of hæmatological changes in heavy manual work and the effects of a ski-ing season on physical fitness. In the psychological section the following subjects have been investigated: job analysis in the metal industry, selection tests for miners, statistical analyses of accident proneness with especial regard to the relationship between age and accident proneness, fitness tests for drivers, method of selecting X-ray assistants for hospitals, studies of the condition of intoxication and so-called "hang-over studies". The report also contains a list of publications of the Institute during the year, which was marked by twenty generous donations amounting to a total of 1,350,000 Finnish marks. The donors came from industry, insurance companies and workers' organizations.

Pest Infestation Laboratory: Report for 1953

The annual report for 1953 of the Pest Infestation Laboratory, Slough, of the Department of Scientific and Industrial Research (pp. iv+46+4 plates. London: H.M.S.O., 1954; 2s. net), shows that the range of activities of this centre of entomological research continues to enlarge. During the year the new biochemical laboratories were opened, and this will greatly facilitate the more fundamental work in which the metabolism of various insecticides is being studied, with the object of discovering their mode of action and the nature of the resistance which many insects are developing to certain types of insecticides. But the greater part of the work reported is of immediate practical importance. The ability of a wide range of pests and potential pests to survive under winter conditions in unheated buildings has been studied. In preliminary trials it has been found that sacks impregnated with a mixture of pyrethrins and piperoxyl butoxide retain their insecticidal properties from six to nine months. A simple electrical device, depending upon changes in conductivity, has been developed for rapid estimation of the water-content of bagged grain. Although not so accurate as the usual methods, this procedure is extremely simple and rapid and should prove of much practical value. One of the most important changes in policy which is apparent in this report is a great increase in the amount of work which the Pest Infestation Laboratory is doing for the British Colonies. Most of these investigations concern storage problems, such as the underground storage of grain in pits, the susceptibility of rice to attack by mites, and the contamination of African maize by insect remains and much other filth since the adoption of hammer mills in place of the old method of winnowing the grain and grinding between stones or by pestle and mortar. It is a recommendation of the Pest Infestation Research Board that the Colonial side of the Laboratory's work should be still further strengthened.

Cytology of *Puccinia coronata*

Studies of chromosomes in germinating sporidia of *Puccinia coronata* f. *secalis*, by R. C. McGinnis (*Canad. J. Bot.*, 32, 213; 1954), show that three are present in the haploid nucleus. Hitherto, the very minute size of the chromosomes in the rust fungi has tended to deter cytologists from tackling these organisms. In an earlier paper (*ibid.*, 31, 522; 1953) the same author has reviewed the literature and also recorded a haploid chromosome number of six for *P. graminis* and presented evidence of polyploidy. For if this species is an auto- or allotetraploid, then species with a lower chromosome number must have contributed to its origin. The present study contributes part of the relevant evidence: one of the illustrations shows a nucleus at anaphase with six daughter chromosomes migrating to the poles. It is suggested that three is probably the basic number for the genus and that *P. coronata* may be a constituent species of *P. graminis*.

Forestry in New Zealand

The New Zealand Forest Service has started a new "Information Series" of pamphlets, the first number of which is entitled "Forestry in New Zealand" and is an extract from the "New Zealand Official Year-Book" (pp. 27. Wellington: Government Printer, 1953). The pamphlet is written for the public and deals with the present position of forestry in New Zealand under the headings of national forest policy, forest resources, forest authority, forest management, fire protection, soil conservation, public and private forestry, reclamation of sand dunes, finance of State activity, forest utilization, overseas trade research, principal forest trees, and strength properties of New Zealand timbers. The annual reports of the Service deal with those aspects of forestry work in the routine fashion. But, as the director of forestry complained in his annual report for 1950–51, the public does not read these reports—a fact scarcely to be wondered at in any country where government routine reports are in question. The pamphlet here considered is the director's answer. A periodical brief review for the public of the forestry position in every country owning forests drawn up on these lines would prove of interest to many public men apart from the general reader. The opening statement on national forest policy displays both the object and method of the pamphlet. Forest policy is essentially one of conservation of all existing forests and expansion in bringing on to the ground additional forest areas where they are obviously required, whether of indigenous or exotic species, both on uplands and plains. Not only productivity, but also protective scenic and recreational facilities, should be considered in the objectives. In short, a national forest policy should be drawn for the maximum understanding and enjoyment by the public of those economic and social benefits which forests alone can confer.

Courtaulds' Scientific and Educational Trust Fund: Postgraduate Research Scholarships for 1954

The Courtaulds' Scientific and Educational Trust Fund has recently announced the award of its postgraduate scholarships for 1954, these being the sixth such awards to be made since the formation of the Fund in April 1948. The Fund provides for the establishment and maintenance of scholarships to encourage study and research in those branches of natural science which may be thought likely to assist the textile, plastics or other allied industries. Postgraduate research scholarships in a branch of science related to the textile, plastics and allied industries (maximum of £400 for one year only, but renewable for further periods) have been awarded to the following for research at the places indicated: C. S. Chadwick (Manchester College of Technology), K. H. Garrett (Imperial College of Science and Technology, London), J. H. M. Hill (The Queen's University, Belfast), R. M. Hochestrasser (University of Edinburgh), R. Johnston (University of Liverpool), G. R. Kotten-Kaye (Royal College of Science, Imperial College of Science and Technology, London), J. H. Oxley (University College, London), P. R. Sewell and R. Worrall (University of Birmingham), and T. C. Stening (King's College, London). Postgraduate research scholarships in textile technology (£320 for the first year and £360 for the second year) have been awarded as follows: E. Attle, S. L. Fitton, K. Jarnell and A. Powell (Manchester College of Technology), D. Hardisty, W. G. Kaye, J. A. Leathley and A. Selwood (University of Leeds), and C. D. Ward (Nottingham and District Technical College).

Royal Technical College, Glasgow: Report for 1952–53

This report on research for the session 1952–53 carried out at the Royal Technical College, Glasgow (pp. 40; 1954), gives a brief indication of the range of research in progress in the Departments of Mathematics, Natural Philosophy, Chemistry, Technical Chemistry, Metallurgy, Civil and Mechanical Engineering, Electrical Engineering, Mining Engineering, Architecture, Town Planning and Building, Pharmacy and Bakery, Textile Technology and of Industrial Administration. To most of these departmental summaries a list is appended of the most important publications during the year, with abstracts, and the titles of theses approved for higher degrees are also listed separately under departments. The report replaces the former *Journal* of the Royal Technical College, the publication of which has now ceased.

Colonial Service: Recent Appointments

The following appointments have recently been made in the Colonial Service: P. S. Castle and L. F. Derraugh (agricultural officers, Gold Coast), senior agricultural officers, Gold Coast; W. E. M. Logan (regional assistant conservator of forests, Tanganyika), deputy chief conservator of forests, Tanganyika; R. G. Sangster (deputy chief conservator of forests, Tanganyika), chief conservator of forests, Tanganyika; W. J. Gray (veterinary officer, Nyasaland), veterinary officer, Northern Rhodesia; J. McCulloch (principal veterinary officer, Eastern Region, Nigeria), deputy director of veterinary services, Northern Region, Nigeria; R. I. McQuistan, agricultural officer, Sierra Leone; J. B. Taylor and B. Woodhead, agricultural officers, Nigeria; R. K. Claydon, veterinary officer, Nyasaland; M. R. E. Durand, veterinary officer, Kenya; D. Bleackley, geologist, British Guiana; D. I. Nicholson, ecologist, North Borneo; D. Slater, veterinary officer, Nigeria.

Announcements

To mark the bicentenary of the birth of William Murdoch, pioneer of the gas industry, a Murdoch Memorial Lecture has been arranged by the Institution of Gas Engineers, which will be delivered by Dr. Alexander Fleck, chairman of Imperial Chemical Industries, Ltd., in the Lecture Theatre of the Royal Institution, Albemarle Street, London, W.1, on October 5, at 6 p.m. Admission to the Lecture will be by ticket. Further information can be obtained from the Secretary of the Institution at 17 Grosvenor Crescent, London, S.W.1.

The Scottish Group of the Nutrition Society is holding a symposium at Dundee on October 23 dealing with "Disorders of the Alimentary Tract and their Nutritional Effects". Papers will be read that deal with the absorption of vitamins, minerals and fat, and also on the subject of food allergies. Further information can be obtained from Prof. R. B. Hunter, Department of Pharmacology and Therapeutics, The Medical School, Queen's College, Dundee.

The Sciences Committee of the Scientific Film Association is arranging a meeting to take place in the theatre of the Shell Film Unit, Shell-Mex House, Strand, W.C.2, on October 14, at 6.30 p.m., for the introduction and exhibition of films made to record or illustrate advances in chemical research—pure, physical or applied. The meeting is to demonstrate how film-making can implement investigational work. The meeting is open to the public.

The sixth Canadian High Polymer Forum, which is devoted to all aspects of high polymer chemistry, will be held at Ridley College, St. Catherines, Ontario, during April 14–15, 1955. Contributions to the Forum should be sent as soon as possible to the programme chairman, Dr. H. L. Williams, Research and Development Division, Polymer Corporation, Ltd., Sarnia, Ontario, and confirmed with a two-hundred word abstract not later than February 15. Inquiries regarding accommodation should be directed to Mr. D. S. Fensom, of Ridley College. General information on the Forum can be obtained from the secretary-treasurer, Dr. D. G. Ivey, Department of Physics, University, Toronto, Ontario.

An official Catalogue of the National Collection of Yeast Cultures is now available from the Brewing Industry Research Foundation, Nutfield, Redhill, Surrey, where the Collection is maintained.

Erratum. The report of the Royal Meteorological Society's symposium on "The Upper Atmosphere" (*Nature*, August 21, p. 334) contains an incorrect statement about the directions of *F*-region movements observed from the Jodrell Bank Experimental Station. In the auroral zone the drift movements are predominantly towards the west during the period 09–21 hr. and towards the south-east or south-west thereafter. In the zenith the movements are towards the west during 18–01 hr. and towards the east during 01–05 hr. A detailed account of these observations is given by Maxwell and Dagg (*Phil. Mag.*, 45, 551; 1954).

SOCIETY FOR THE STUDY OF FERTILITY

ANNUAL CONFERENCE

THE annual conference of the Society for the Study of Fertility was held in the Meeting House of the Zoological Society of London during July 22–23, when the opportunity was also taken to celebrate the fifth anniversary of the Society's existence. The proceedings opened with a paper by R. Irving-Bell on the routine clinical examinations carried out at the Male Subfertility Clinic at Bristol, followed by a group of three papers from the Department of Anatomy, Liverpool, by Prof. R. G. Harrison and his colleagues, on some fundamental aspects of the structure and function of the rat testis and the male accessory organs. In the first paper, concerned with the influence of freezing temperatures on the rat testis, Prof. Harrison and Miss Jean Macdonald elaborated in detail their thesis that the adverse effects of low temperatures on spermatogenesis are due directly to ischæmia. Next, E. W. Macmillan gave an account of his experiments on the anatomical factors in the male which determine the normal rate of disposal and dissolution of epididymal spermatozoa, and which predispose to the formation of spermatocoele. E. J. Clegg described the response of rat accessory glands to the interruption of arterial blood supply. His finding that, when deprived of the normal blood supply, the coagulating glands cease to secrete fructose is a good indication that the blood-flow in the accessory reproductive organs is of decisive significance for composition of the seminal plasma.

Dr. Cecilia Lutwak-Mann (Cambridge) spoke next on the physiology and biochemistry of the near-implantation stages of pregnancy in the rabbit. She has found that very little glucose is present in the young unattached blastocyst (six days after fertilization), but that the content of this sugar begins to increase markedly as implantation progresses. This is in contrast to the content of bicarbonate ions, which in the unimplanted blastocyst are almost three times more concentrated than in the maternal blood but which decrease to maternal serum-level after the implantation. The remarkably high content of bicarbonate in the free-lying blastocyst coincides with the appearance in the mucosa of the pregnant uterus of carbonic anhydrase, the zinc-protein enzyme which is well known to be concerned with bicarbonate metabolism in the animal body. From Dr. Lutwak-Mann's experiments concerning the passage of a variety of substances from the maternal blood stream into the blastocyst, it appears that, so long as the blastocyst remains free in the uterus, it is largely independent of major changes in the maternal blood composition. Once implantation is completed, several substances, including certain drugs, are capable of passing freely from the maternal blood into the blastocyst cavity.

This paper was followed by a group of three reports, all of them concerned with different clinical aspects of human infertility: D. M. Shotton (Birmingham) spoke on the obstetric management of infertile women, M. C. N. Jackson (Exeter) presented her records on the follow-up of infertility cases, extending over many years of observation, and Dr. J. Loewenstein (London) described in detail the use of mechanotherapy in subfertile men.

The session on the next day opened with a paper by Dr. E. J. Farris (Philadelphia) on the value of ovulation timing in the sterile couple, followed by two other guest-speakers from abroad: Dr. G. E. Seegar Jones (Baltimore), who discussed the relationship between adrenal hyperplasia and fertility, and Dr. Raoul Palmer (Paris), describing the use of cœliscopy in the diagnosis of reproductive disorders in women. The remaining papers centred largely on the problem of male sterility and sperm physiology and biochemistry. Dr. G. I. M. Swyer (London) commented critically on the value of testicular biopsy as a clinical procedure. Dr. A. S. Parkes and Dr. P. Spensley, from the National Institute for Medical Research, Mill Hill, reported on their experiments with 'Rehibin', a condensation product of gentisic acid, and on certain other new macromolecular polyacids in relation to their action on hyaluronidase and the fertilizing capacity of rabbit spermatozoa. An interesting fact brought to light by these researches was that, in spite of the marked inhibitory effect on sperm-hyaluronidase which coincided with a decrease in fertilizing capacity, 'Rehibin' and similar polyhydroxybenzoic acid condensation products are not necessarily spermicidal agents—for example, they do not deprive the spermatozoa of their motility and metabolic activity.

Metabolic processes in spermatozoa and their relation to the so-called dilution effect were dealt with by Dr. M. W. H. Bishop (Cambridge), who reported also on the use of a new glycine-containing artificial medium in the practice of semen preservation. He was followed by Dr. T. Mann (Cambridge), who spoke on the biochemical mechanisms underlying the action of spermicidal agents, and on his recent investigations which make it possible to distinguish clearly three groups of spermicidal substances: enzymic inhibitors, which act directly upon certain intermediary reactions in sperm respiration and fructolysis; sulphydryl-binding substances which combine with the vital thio-groups in spermatozoa; and surface-active substances which owe their spermicidal property to a detergent action on lipoprotein and other protein-constituents of the sperm-cell.

As in previous years, the papers presented at the Conference will be published by W. Heffer and Sons, Ltd., Cambridge, as a separate volume (No. 6) of the *Proceedings of the Society for the Study of Fertility*.

METEOROLOGY AND SCOTTISH AGRICULTURE

TWO symposia were held by the Royal Meteorological Society as part of its summer meeting during July 15–17 in the Natural Philosophy Department of the University of Edinburgh. The first was on "The Upper Atmosphere" (see *Nature*, August 21, p. 334), and the second, which was held on July 17, was devoted to "Meteorology and Scottish Agriculture". The first speaker at this latter symposium was Dr. John Grainger (West of Scotland Agricultural College, Auchincruive), who suggested, by graded examples, that studies on relationships between climate and crop diseases should consider effects on the host plant, in addition to those on the parasite.

The attainment of a soil temperature of 45° F. (7·2° C.), for example, imposes an initial limit to the activity of larvæ of the potato root eelworm, with no such limit to growth in the early Epicure potato-host. This has important economic and pathological repercussions, and the growth of such early crops provides, moreover, the only cultural possibility of obtaining even moderate yields on infested land. Low incidence of club root disease of swedes is associated with a relatively high soil temperature in July, relatively high amounts of bright sunshine in June, July and September, relatively low rainfall in September, and relatively high rainfall in October. The effect of bright sunshine on disease can only arise through its effect on the host. Practical measures for the grower would be to control soil moisture in September and October.

A second paper by Dr. Grainger, in which he had collaborated with J. L. Sneddon, E. de C. Chisholm and A. Hastie (Auchincruive), reported that higher yields of barley grain are related to lower maximum air temperature and higher rainfall in June. The production of bean grain is stimulated by higher average maximum air temperature in May, lower bright sunshine in June, and higher rainfall in July. Yields of oat grain are higher with lower average air temperature in July, and wheat grain with lower average air temperature in April and higher rainfall in July. Winter varieties of wheat give higher yields of grain when, in addition to these correlations with climate in April and July, there is a lower amount of bright sunshine in March. The practical value of the results lies in the precision they bring in suggesting that conservation of soil moisture is most necessary in particular months for each crop in a given area.

Dr. F. L. Waterhouse (University College, Dundee; University of St. Andrews) gave detailed assessments of seasonal and diurnal differences in climate within grass crops, with the view of their suitability for the development and successful existence of insects. The differences are mainly related to the height, density and mode of growth of the crop and also to the angle of the sun's rays. A matted basal layer of dead grass in wild grassland, or the co-existence of a clover crop in hay and silage fields, maintains a cool humid atmosphere next to the ground. This is favourable to insects when more arid conditions exist at higher levels, where wind speed is the most significant factor. These varying conditions can make available to an insect a considerable range of body temperatures and states of water-loss during periods of insolation. The presence of broad-leaved weeds can interfere with the relatively uniform habitat presented by pure grassland.

A preliminary report on continuous records of profile soil temperatures within an afforested area was given by Dr. J. R. H. Coutts (Soil Science Department, University of Aberdeen), who said that mean annual temperatures were found to be practically the same throughout the soil profile, but that inversions of the profile occurred in April and August. Future results from this study should yield information of considerable importance. Mr. J. M. Caborn (Forestry Department, University of Edinburgh) reviewed work on the effect of shelter belts on the climate of the areas influenced by them. He laid stress upon the density of the shelter. A completely dense belt, for example, is 80 per cent ineffective at 10 heights away in the lee, whereas a less-dense belt is effective 15 heights away, and a density of 50 per cent has been found to be the most effective. In detail the temperature in the lee of a shelter belt is often 1° F. higher than in the open, during the day; relative humidity is about 3 per cent less in the lee, and soil moisture is about 1 per cent higher in this area. Crop yields have also been found to be higher in the lee of shelter belts.

Mr. F. H. D. Green (Nature Conservancy) considered the importance of climate and climatic studies on the ecological work of the Conservancy. One important conclusion is that the climate and conditions in mountain-top valleys should not be considered on a basis of their floor altitude, but as part of the mountain top itself. An indirect effect of summer rainfall on the response to phosphatic fertilizers was mentioned by Dr. A. M. Smith and Dr. K. Simpson (East of Scotland College of Agriculture, Edinburgh). It is fairly common knowledge that response to phosphatic fertilizers tends to be small in a dry season and high in a wet one. It was found, however, that the percentage recovery of phosphorus is more closely related to soil pH than to summer rainfall. The correlation between phosphate recovery and soil pH is, nevertheless, much more significant when the effects of summer rainfall are eliminated.

The symposium served a most useful purpose. Biologists and meteorologists have remained separate for too long, and it is to be hoped that this conscious joining of their forces may be followed by further similar meetings.

ROYAL GREENWICH OBSERVATORY

ANNUAL REPORT FOR 1953–54

THE annual report of the Astronomer Royal for the period May 1, 1953–April 30, 1954 deals as usual with three separate sections of the Royal Greenwich Observatory in Greenwich, Abinger and Herstmonceux*. The Greenwich Octagon Room, which was formally opened on May 8, 1952 (referred to in last year's report), is accessible to the public, and Halley's transit and Bradley's zenith sector are displayed in the room, as well as copies of various old prints of the Observatory. A considerable amount of work has been done to the New Building, and the hot-air furnaces have been overhauled; repair and maintenance work has been carried out in the old buildings, and the boundary fences have been repaired and strengthened. A new boiler has been installed for heating the Record Rooms and Time Department Office.

The Yapp 36-in. reflector has been used with the single-prism spectrograph in continuation of observations of the standard stars of the Yerkes Atlas, and 86 spectra of 74 stars have been secured. During October 30–April 26, while the 21-ft. eclipse telescope was under test, the instrument was out of use. In last year's report reference was made to the proposal to televise Jupiter and its satellites, and on January 13 the scheme was carried out with great success; unfortunately, the next night, on which a full-scale programme was scheduled, was cloudy, and a 'stand-by programme' had to be substituted.

* Report of the Astronomer Royal to the Board of Visitors of the Royal Greenwich Observatory, Read at the Annual Visitation of the Royal Observatory, June 12, 1954. Pp. 30. (Herstmonceux: Royal Greenwich Observatory, 1954.)

Observations at the Magnetic Observatory, Abinger, are so disturbed by the local electric railways that the Board of Admiralty has approved, in principle, its removal to a site near Hartland, North Devon. It is highly desirable that observations in the new site should begin not later than the middle of 1957, and an overlap of observations with those at Abinger of at least a year will, it is hoped, include the International Geophysical Year. If it does, the magnetic data for that year would then include results from two observatories in the south of England and from the two northern observatories at Lerwick and Eskdalemuir.

While substantial progress in the removal to Herstmonceux has been made, it is disappointing that delays in the construction of the meridian group of buildings have taken place; the transit circle building is still unusable, and the photographic zenith tube building has only reached the foundation stage. The decision by the Admiralty that no official houses for the observing staff will be provided at Herstmonceux increases the need for close co-ordination between the building programme at the Observatory and the provision of houses for the staff through the local Rural District Council. The delay in the completion of the consulting architect's plans for the buildings to house the Time Department, the Nautical Almanac Office and the workshops will still further postpone the date of the removal.

Mr. J. Evershed has presented the Observatory with the principal parts of his solar spectroscope from his private observatory at Ewhurst; these include a coelostat for a 15-in. mirror, a train of three large liquid prisms and many accessory items. He had previously presented the Observatory with a pair of large solid glass prisms of 45° angle and a 21-ft. collimator lens. The large reflecting prism of 30° angle which the Royal Society had lent him has been transferred to the Observatory.

Cosmic ray recording with the Clintel apparatus has been continued, but some of the data obtained were unreliable: some modification of the apparatus has, in consequence, been done. The investigations of the atmospheric cosmic-ray Čerenkov effect have been discontinued because the slit in the solar dome was found to be too narrow for a satisfactory arrangement. A project of high-energy shower recording has been given some consideration.

The "Nautical Almanac" for 1955, which was published in April, contains a list of observatories, the first it has given since 1941, and, generally speaking, the list is confined to those observatories of which the work demands a knowledge of accurate values of the geographical co-ordinates. To comply with the recommendations of the International Astronomical Union made at the Eighth General Assembly in Rome in 1952, the first part of the "Nautical Almanac" for 1960 has been completely redesigned, and preparations of copy for 1960 will soon be started. Good progress has been made in the calculation of the ephemerides of the sun and planets for the years 1960–80. In the report of the Observatory for 1952–53, reference was made to the preparation of illustrative examples for the use of different methods of calculating perturbations of comets and minor planets for the third volume of "Planetary Co-ordinates", and Encke's method has been completed, while Hansen's method is nearly finished. Some progress has been made with the method of variation of elements and with Herrick's method of variation of parameters. In connexion with the "Star Almanac", the 1955 edition of which is expected to appear in June, it is interesting to know that it is now an established success and that reprints have been necessary in 1953 and 1954 in spite of printing increased numbers.

The figuring of the 98-in. disk of the Isaac Newton telescope has been suspended pending further tests in August during the works holiday period, when there will be an absence of vibration from heavy machinery. The broad features of the design of the mounting have been decided: it will be an offset fork mounting with polar axis in the form of an inverted and truncated cone.

INDIAN ASSOCIATION FOR THE CULTIVATION OF SCIENCE

ANNUAL REPORT FOR 1953–54

THE annual general meeting of the Indian Association for the Cultivation of Science was held on July 30 at Jadavpur, Calcutta. Prof. P. Ray, acting director, in presenting the annual report on the Association for 1953–54, said that the six research departments, the library, the workshop and the administrative office continued to function actively for the third year in the new research laboratory building at Jadavpur. The Association has prepared a five-year plan of development, covering the financial years 1954–59, which envisages, for the existing departments, the expansion of facilities with respect to equipment and staff so as to consolidate the present research activities and also improve the level of efficiency, but does not involve establishment of any new department. For the five years 1954–59, the non-recurring requirements of the Association for equipment, standard reference books, etc., have been worked out at Rs. 1,138,200, and the projected development under land and building would involve an expenditure of Rs. 1,771,393. During the same period the normal recurring grant for running the Association will have to be increased from Rs. 465,630 in 1954–55 to Rs. 777,415, thus requiring a total sum of Rs. 3,227,592 for the entire five-year period. It is expected that the Association's non-recurring demand will be met by the Government of India and the Government of West Bengal in the proportion of 2 : 1. The present recurring charges will continue to be borne by the Government of India, and it is expected that the additional requirements will be also borne by the Governments of India and of West Bengal in the proportion already mentioned.

Prof. Ray reported that the Association has under operation four research schemes of the Council of Scientific and Industrial Research of the Government of India, three research schemes under Prof. S. R. Palit and one under Prof. B. N. Srivastava. The Government of India, through the Ministry of Natural Resources and Scientific Research, has established a number of senior and junior scholarships for providing research training to deserving students at the Association under the Scientific Man-Power Committee Scheme.

During the year the Association started a publication section and undertook the publication of a number of books and monographs, including a book on the history of science in Bengali, "Bijnaner

Itihas", by Sri S. N. Sen, which was subsidized by the Government of Bengal, "Nuclear Induction", by Dr. A. K. Saha and Sri T. P. Das, and a monograph, "Non-aqueous Titration", by Dr. S. R. Palit, Dr. M. N. Das and Sri G. R. Somayajulu. Of the lectures given during the year, Prof. G. I. Finch, who was awarded the Association's Jay Kissen Mookerjee Gold Medal for 1950, delivered a course of three lectures on electron optics and study of surfaces, crystal growth in electro-deposition and in surface reactions, and polish, mechanical wear and lubrication; and another course of three lectures was given by Dr. J. N. Ray, as Coochbehar professor for 1949, on carbohydrate metabolism and the role of some plant nucleotides in the phosphorylation of glucose, curariform drugs and their action and anæsthetics. The Ripon professorship lecture for 1950 was delivered by Prof. T. R. Seshadri, who spoke on a line of investigation in the field of plant drugs and insecticides, and Dr. S. K. Banerjee, Dr. M. S. Krishnan and Dr. D. S. Kothari, the Ripon professors of the Association for the years 1948, 1949 and 1950, delivered lectures on, respectively, Himalayan earthquakes; ancient Indian iron-ore and its manufacture, the iron ore deposits in India, and the modern iron industry in India and its future prospects; and recent advances in statistical thermodynamics. Dr. Dilip Kumar Banerjee was awarded the Sri John Wood Burn Medal for 1950 and gave a lecture on steroid synthesis. Dr. J. C. Ghosh, the retiring president of the Association, delivered the Memorial Lecture, speaking on the petroleum industry with special reference to India, this being the occasion of the fiftieth anniversary of the death of the late Dr. Mahendra Lal Sircar, the founder of the Association. A symposium on high polymers, including rubber, resins and plastics and fibre, was organized during the year by the Department of Physical Chemistry of the Association, and was followed by a very successful three-day summer course on the subject.

In his report, Prof. Ray gave a brief review of the work carried out in the six research departments of the Association during 1953–54. In the Department of General Physics, X-rays and Magnetism, studies were made on transport properties of matter, thermodynamics of irreversible processes, low-temperature physics, X-ray crystallography, study of low-angle scattering, X-ray study of coal, X-ray study of glass, crystal magnetism, cryogenics, and semiconductors. Investigations carried out in the Department of Optics have related to ultra-violet absorption spectra or organic substances in the solid state at low temperatures, Raman spectra of some organic compounds in the solid state at low temperatures, Raman spectra of organic compounds in the vapour state, Raman spectra of liquids and solutions, relaxation time of polar molecules in the liquid state, absorption of ultra-high-frequency radio waves by organic liquids, absorption of microwaves by organic liquids, and cosmic rays. In the Department of Theoretical Physics, investigations were carried out in meson field theories and nuclear scattering, Born approximation and its connexion with covariant perturbation theory, capture of electrons by ions passing through gases, cosmology, and nuclear shell structure model. The Physical Chemistry Department has conducted its research activities under two broad headings: high-polymer chemistry, and general physical chemistry. Under high-polymer chemistry some of the problems investigated relate to chain transfer in vinyl polymerization, copolymerization, kinetics and chain transfer studies in polymerization initiated by hydrogen peroxide, vinyl polymerization with metallic soaps, kinetics and chain transfer studies with substituted peroxide and azonitriles, synthesis of hydro peroxides and their use in polymerization, polymerization in the aqueous phase, physico-chemical studies on cellulose compounds, polyelectrolytes, studies on reaction kinetics, fractionation and distribution of polymers. Kinetics of the decomposition of peroxides, studies in co-solvency, non-aqueous titration, alkalimetric determination of mercury, and measurements of dipole moment constituted some of the problems of study under general physical chemistry during the year. In the Department of Organic Chemistry, work was carried out in diterpenoids, dicyclic terpenes, steroids, polynuclear aromatic hydrocarbons and related subjects. The chemistry of co-ordination complexes and analytical chemistry were the two broad subjects for investigation by the research workers of the Department of Inorganic Chemistry.

The complete Council of the Association is as follows: *President*, Hon. Sri C. C. Biswas; *Vice-Presidents*, Prof. S. K. Mitra and Dr. K. S. Krishnan; *Director*, Prof. M. N. Saha; *Members*, Prof. N. R. Sen, Dr. Atmaram, Dr. B. C. Guha, Dr. Triguna Sen, Prof. P. C. Mahanti, Sri Ramani Mohan Roy, Dr. J. C. Ghosh, Dr. Hiralal Roy, Dr. B. B. Dey, Dr. S. R. Bose, Sri J. M. Sen and Dr. D. N. Wadia; *Trustee Member*, Hon. Mr. Justice R. P. Mookerjee; *Nominees of the National Institute of Sciences of India*, Dr. K. N. Bagchi and Prof. D. S. Kothari; *Nominees of the Government of India*, the Secretary of the Ministry of Natural Resources and Scientific Research (or his nominee), the Educational Adviser to the Government of India (or his nominee), Sri C. S. Menon, and the Joint Secretary to the Ministry of Finance, Government of India; *Nominee of the Government of West Bengal*, Dr. D. M. Sen; and *Professor Member*, Prof. B. N. Srivastava.

MELLON INSTITUTE, PITTSBURGH

ANNUAL REPORT FOR 1953–54

THE annual report of the president of the Mellon Institute, Dr. E. R. Weidlein, to the Board of Trustees for the year ended February 28, 1954*, refers to growth in the size of fellowships in operation and an increase in comprehensive fundamental projects. Almost a quarter of the Institute's expenditure of 4,375,712 dollars was spent on investigations in pure science in the Institute's six research departments and on eleven fellowships, 131 members of the Institute being engaged in pure science research projects. 383 members were engaged in the sixty-five fellowships in applied science, and, of forty-nine multiple fellowships and twenty-seven individual fellowships listed as in operation during the year, two had been proceeding for forty years, five for thirty-five, one for thirty, ten for twenty years and twenty-five others for more than ten years.

In the Department of Chemical Physics the Raman spectrum of dicyanoacetylene has been redetermined on a larger sample, using a new grating in the Raman spectrograph. The Raman-active fundamental postulated at 260 cm.$^{-1}$ in earlier work has now been observed at 263 cm.$^{-1}$, and the vibrational spectrum of hexafluoro-Δ^{2}-butyne has been interpreted in fairly complete detail. An extensive survey was made of the alkali metal content of calcite marbles by emission spectrographic analysis, and an earlier photographic technique for the study of the diffraction structure of carbon black has been replaced by a speedier and more accurate X-ray spectrometric method, in which the monochromatization of the X-ray beam is achieved through the low sensitivity of the argon-filled Geiger tube for the short wave-lengths of the white radiation, and a small residual correction made empirically. An improved quantitative method has been developed for measuring crystallinity in elastomers, and an instrument has been constructed for the precision measurement of linear distances on diffraction films.

---

* Scientific Research of Mellon Institute, 1953–1954. (Annual Report Series, No. 41.) Pp. iv+56. (Pittsburgh: Mellon Institute of Industrial Research, 1954.)

In the Physical Chemistry Department the Mellon Institute digital computer was being built for a new Department of Applied Mathematics, and is of the low-speed magnetic drum type with large storage capacity. At the end of the year this Department was combined with the Department of Physical Measurements, which has been responsible for several advances in the application of thermal diffusion to the separation of organic liquids, and has recently modified the gas-adsorption apparatus so as to permit the use of krypton or argon-gas for surface-area measurements of materials with low area. In the Department of Instrumentation a method has been devised for the determination of humidity based on the titration of a concentrated solution of lithium bromide with water until the solution humidity balances the atmospheric humidity, and a preliminary study made of the electrical pulse transmission characteristics of sodium chloride solutions.

A programme of research on drug standards which has been continued for twenty-three years in the Department of Organic Chemistry has now been divided, leaving the Department responsible for aromatic chemicals and surgical supplies. It is hoped now to turn attention to the development of systematic schemes for distinguishing chemically the individual analogues in groups all of which possess therapeutic value, and to the investigation of the use of heteropoly inorganic acids in the determination of organic bases. In the Division of Analytical Chemistry an attempt was being made to develop a scheme of analysis for sulphur compounds in crude oil and petroleum fractions, while the study by the Division of Microbiology and Microscopy of the bacteriology of bituminous coal-mine effluents has given a clearer understanding of the bacterium responsible for increasing the formation of acid from sulphuritic materials associated with bituminous coal.
